Niagara Falls, Ont.—The ratepayers will vote on a by-law calling for the expenditure of $7,500.00 on a new centrifugal pump. J. C. Gardner, city engineer.

Regina, Sask.—Mr. T. Aird Murray and Dr. M. M. Seymour, Provincial Medical Health Officer, recently paid a visit to Qu'Appelle to oversee well drilling operations going on at that point and to make investigations regarding the quality of the water.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Aylmer, Ont.—Mr. George W. Howse is making preliminary plans and estimates for the erection of a brick block.

Galt, Ont.—The management of the Galt Robe Works have arranged to build an addition to their present plant at a cost of $17,000.

Gerrard, B.C.—The Dominion Department of Marine and Fisheries will erect a large fish hatchery at this point Mr. F. A. Starkey, president of the Associated Boards of Trade of Eastern British Columbia is interested in the matter.

Lethbridge, Alta.—A letter received by the municipal authorities states that a contract calling for the erection of a new post office will be awarded within a few weeks by the Department of Public Works, Ottawa. The estimated cost of this work will be about $225,000.

Medicine Hat.—The management of the Alberta Glass Company have started work on their new plant. The building will cost about $10,000, and there will be required about $70,000 worth of machinery. Mr. W. Walch has been awarded the contract to erect the factory.

Port Arthur, Ont.—The Royal Hotel has been sold to Mr. Theo. Williams, of Winnipeg, Man., acting for an English syndicate and it is reported that a number of large stores will be erected.

Regina, Sask.—The Hospital Board have authorized the calling of tenders for the erection of a power house and laundry building to cost $75,000.

Sydney, C.B., Nova Scotia.—A report states that the management of the Alexander Cross Fertilizer plant are considering plans for the doubling of their present manufacturing facilities. C. R. Walker, general manager.

Toronto, Ont.—A report states that the management of the Canadian [illegible] will construct a large wharf at the foot of West Market Street 600 feet long and 100 feet in width.

Second Narrows, B.C. Plans and specifications of the Second Narrows bridge are practically completed with the exception of those portions depending upon the width of the draw span, and at a meeting of the Burrard Inlet Tunnel and Bridge Co. it was decided that construction work should start as soon as possible, the plans to include an opening span of 200 feet, in accordance with the order of the Railway Commissioners.

Vancouver, B.C. The Parks Commissioners have awarded a contract to have all the roadways oiled by a private firm once a month for the sum of $140.

Victoria, B.C.—The ratepayers of a certain section of this city are angered over the action of the British Columbia Telephone Company in attempting to tear up a pavement just two weeks old. It is probable that an injuction will be secured to refrain this action on the grounds that repaired pavement is inferior to that first laid.

Winnipeg, Man.—The municipal council has given notice of its intention to construct a sewer on Edward Street at an estimated cost of $341. Col. N. H. Ruttan, city engineer.

CURRENT NEWS.

Calgary, Alta.—The ratepayers will vote on the following by-laws, August 23rd:—To spend $405,000 on the enlargement of the water plant. To grant $150,000 to the Board of the Calgary General Hospital to be used in construction work. To spend $32,000 on the purchase of a portion of land to be used for public works purposes.

Cheam Lake, B.C.—W. B. Ellis, of Vancouver, has applied for a lease of the submerged bed of Cheam Lake in the railway belt of British Columbia, for the purpose of pumping or dredging from the lake a deposit of disintegrated lime to be used for fertilizing purposes. The department of agriculture for British Columbia recommends that the lease be granted as there is a great need for crushed lime rock for fertilizing. The term of the lease proposed is five years.

Edmonton, Alta.—A clause in the new building regulations adopted by the municipal council states that all buildings erected in future shall not be of a greater height than ten stories.

Montreal, P.Q. On the mornings of Thursday, August 29th, and Friday, August 30th, there will be held by order of the Board of Control, an auction sale of building materials, stone, brick, wood, etc. The purchaser will be required to [illegible] buildings. Further particulars may be had from [illegible] of Board.

Port Arthur, Ont. [illegible] will vote September 16, on the question of [illegible] the alternative [illegible] from one to two years.

Victoria, B.C. [illegible]

CITY ENGINEER'S REPORT, HAMILTON, ONT.

According to a report recently received from the office of A. F. Macallum, city engineer of Hamilton, Ont., expenditure of public moneys on municipal engineering work has been well proportioned and in many instances well within the amount set aside in the appropriations and may be tabulated as follows:—

Sewers expenditure to Dec. 31st, 1911	$ 6,78[illegible].10
Board of Works expenditure	105,606.60
Sewage disposal expenditure	21,454.50
Street lighting expenditure	39,680.58
Street watering expenditure	27,795.12
Waterworks expenditure	66,991.67
Garbage expenditure	42,354.78
Permanent roads expenditure	123,722.98

The local expenditures for the same period are tabulated thus:—

Sewers	$231,289.57
Cement walks and curbs	44,377.05
Waterworks construction	105,108.23
Roadways	10,097.73

During the year several alterations and changes were made in and about the Beach pumping station. A battery of five new boilers was placed in connection with the steam pumping engines, and these engines repaired and placed in good condition. Valves were placed in the wells and conduits so that each well and either conduit could be cut off if necessary. One conduit across the Lottridge inlet was uncovered and surrounded with six inches of concrete. This conduit was also emptied and repaired from within throughout its length wherever necessary.

While the electric pumps, recently installed, each pumped 6,000,000 gallons, as guaranteed, together they pumped but 10,500,000 gallons per twenty-four hours. By enlarging the impellers, which has just been done, this deficiency has been overcome, and the combined capacity of these pumps is now over 13,080,000 gallons per twenty-four hours.

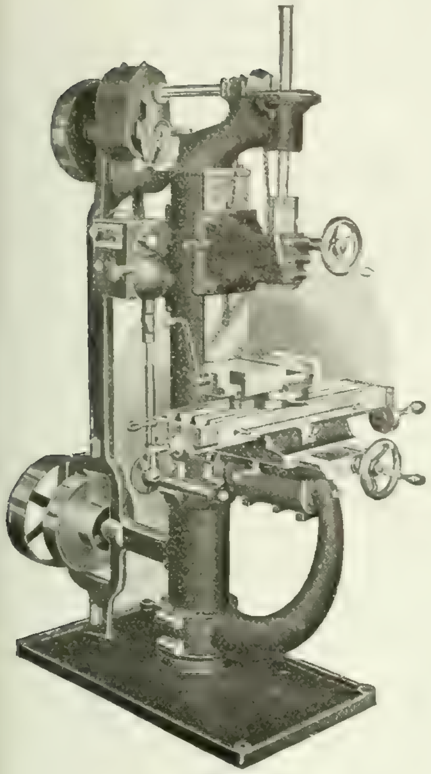
The crib on the end of the short intake to the lake, having been destroyed by ice, was rebuilt, and there is now less danger from blocking up with ground ice.

A new air compressor was placed in the Wentworth Street pump house, and a smaller one of insufficient capacity removed.

The present population of the city is 82,095; the acreage is 6,260, and the assessed value is $52,749,884.

NOVEL CANAL BOAT.

A railroad car driven by axle motors supplied with energy from a power plant carried on board, was recently tried out with considerable success in this country, but what will doubtless prove to be a still more novel combination is expected to appear on the Canadian canals in the near future. This will be a freight ship operating on the same plan, equipped with internal combustion oil engines, shaft-connected to dynamos instead of to the propeller, and the electric power thus developed will be used for driving the screw and handling the other mechanical equipment of the vessel, the captain handling them by switches from a bridge. Many experiments have been made along this line during the past few years in Scotland, and a fifty-foot model vessel was built and successfully operated before the contracts for the ship were let. Although it will be next year before the vessel appears in Canadian waters, the experiment is being watched in naval circles with great interest, and if it proves a success it is likely to be widely adopted not only for canal and lake work, but



You Need a Machine Like This on a Dozen Different Jobs

It's a No. 2 Knight Milling and Drilling Machine

This machine is very rigid, powerful and accurate, so that close work may be turned out with a high degree of satisfaction, and in the shortest possible time. The adjustments are quickly and easily made. On a large variety of work it is possible to make a saving of from 20 to 50 per cent. in time, as compared with other machines.

The fact that hundreds of Knight Machines are now in use in this and foreign countries proves that they are not experiments.

These machines are made in three sizes.

Briefly, the construction of the No. 2 Knight Miller is as follows :—Spindle of crucible steel, ground bearings ; working surface of table, 29 × 8½ inches ; feed, longitudinal and transverse ; floor space, 60 × 68 inches ; weight, crated for shipment, about 2,500 lbs.

MONTREAL, ST. JOHN, OTTAWA, TORONTO, WINNIPEG,
CALGARY, SASKATOON, VANCOUVER, VICTORIA.

[illegible] for the smaller types of war vessels in the British [illegible]

This novel vessel has just been contracted for by the Montreal Transportation Company as the outcome of suggestions and designs made by Messrs. John Reid & Co., of Montreal and Glasgow, with the Electric Marine Propulsion Company, of Glasgow, who are working out this new system of marine progress. The ship is being built to their plans by the Swan, Hunter, Wigham & Richardson firm, while the electric system to be adopted is the invention of Mr. H. A. Mavor, of Glasgow, who has taken a leading part in the adaptation of electricity to marine propulsion.

OLD TIN CANS.

Before the invention of the automatic solder wiper the collection of old tin cans and the heating of the same over a slow fire for the collection of the solder formed the means of profitable employment to certain rag and metal junk men in some of the larger cities in the United States. There has not been much heard of the industry of late owing largely to the economy of the manufacturers in the making of the tin and of the recent improved seam joint that permits of the manufacture of a water-tight can without the use of solder. Lately, however, a firm in Germany began to buy up shipments of scrap tin all over the world and had certain lines of tramp steamers call at stated periods and remove the rubbish from the manufacturing plants. The operation has proved so successful that they are now making propositions to many of the municipal authorities in the larger cities with a view of purchasing all the old tin cans that are now collected as garbage. The offer, as made to the city of Montreal, states that two tin presses would be forwarded and loaned to the council free of charge and that the sum of $6 per ton would be paid for the materials f.o.b., and it was suggested that the garbage collector throw the tins to one corner of his wagon as he makes his daily rounds. The German metallurgists detin the scrap and then melt the sheet iron for pig.

WATER PURIFICATION.

In the presidential address at the annual meeting of the Institution of Water Engineers, recently held in Cheltenham, England, Mr. J. S. Pickering, after a reference to works of [illegible] large [illegible] under construction in this country, urged the vital importance of the quality of a public water supply. Whatever might be the nature of the supply itself constant supervision by a competent engineer and staff was absolutely essential, and what was equally important was systematic and methodical ex[illegible] practice in submitting samples for analysis and bacterio[illegible]

[illegible] initial cost, and working expenses, and might frequently be used where a slow sand filter would be impracticable. The pressure-filter had been given preference over the gravity-filter, chiefly because it could be introduced on the service-main without much loss of head. Mechanical filters, properly arranged, would give as good results as slow sand-filters. The weak point in both types was their impaired efficiency after cleaning, but whereas the former generally had to undergo this operation very thoroughly at least once a day, the latter might continue for weeks without even the surface film being removed.

In many cases where ordinary slow sand-filters were in use, mechanical filters might be introduced as pre-filters with considerable advantage. Experience had proved that after the filtering skin had been removed a filter lost much of its power to remove the micro-organisms from the water, and it was only after running the water to waste for some time and reducing the speed of filtration that it gradually regained its efficiency. These precautions were recognized as necessary by all water engineers, but those who had charge of filters realized the difficulty of carrying them out in practice, particularly as there were no means of really testing the work a filter was doing except by bacteriological examination of the filtrate. As a safeguard, then, against the inefficiency of a freshly scraped filter, and as a second line of defence, as it were, against the passage of pathogenic bacteria into the supply mains, pre-filters were of the greatest value.

Sterilization.—The time would probably come when nothing short of complete sterilization would be acceptable. Many substances were capable of destroying infectious germs, but their application to drinking water had been rendered objectionable owing to a harmful residue left in the water after treatment. The use of ozone was not attended with this difficulty, and in recent years this had been adopted for the sterilization of the water supplies in many large towns. The chief disadvantage was the cost of working, and, until this could be greatly reduced, the process was not likely to become extensively used in this country. The use of hypochlorites had met with success, and had the advantage of being comparatively inexpensive in working. The bactericidal action of the ultra-violet rays had also been applied to the sterilization of water on a fairly large scale. In the "De-Clor" system, in operation at Reading, through the agency of a minute dose of chlorine the objectionable bacteria were destroyed, and the residual chlorine was eliminated by means of charcoal placed within the filters. The "De-Clor" apparatus took the place of ordinary sand filters, the river water undergoing preliminary treatment through coarse pre-filters.

CENTENARY EXHIBITION OF STEAM NAVIGATION IN EUROPE.

Captain James A. Stewart, of 551 Tenth Avenue, Vancouver, B.C., has in his possession a copy of an advertisement of August 5th, 1812, dealing with the Comet, the [illegible] in Europe. The advertisement [illegible]

"Steam Passage Boat, The Comet, between Glasgow, Greenock and Helensburgh, for passengers only. The [illegible] fitted up a handsome vessel to ply upon the River Clyde between Glasgow and [illegible] wind, air and steam, he [illegible] the Broomielaw on Tuesdays, [illegible] and to leave Greenock on Mondays, Wednesdays and Fridays in the morning, to suit the tide.

EDMONTON BENCH-MARKS.

By C. C. Sutherland, Roadways Department, Edmonton, Alberta.

The first bench-mark in the city of Edmonton was chosen on top of a stone ledge of the Bank of Nova Scotia. From this ledge levels were carried out and other bench-marks established, generally on the rim of manhole covers or on nails in electric light or telephone poles.

With the improvement of streets the manhole covers were adjusted and the poles removed, so that it soon became necessary to put in some permanent bench-mark system.

In 1908 a number of brass bolts, turned up at one end, were placed in public buildings throughout the business section of the city. The cost of the brass bolts was $1.25, and when established made a bench-mark costing approximately $3.25 each.

It was intended that as a district developed a complete system of bench-marks would be installed in this way, but for some reason the heavy buildings in the city do not stand well on this soil, and hence do not make good bench-mark supports. For example, we placed a bench-mark on the new Government post-office, and found by comparing it with old-established bench-marks that after one year it had settled 0.10 of a foot.

During the fall of 1909 bench-marks were placed at street intersections over a part of the city. These were made by boring a six-inch hole in the ground to a depth of four feet and refilling with concrete. In the top of the concrete was placed a rounded cast-iron bolt. The location of these bench-marks was kept as uniform as possible, being placed one foot off main streets and six inches from the property line. By this location it came at the inside edge of the plank walk, and was not disturbed by building operations except in some cases where the grade was lowered. The costs when complete was approximately $5. In dry, well-drained soil the elevations seem to remain constant, but in wet places it is found that the bench-marks have risen, probably due to frost.

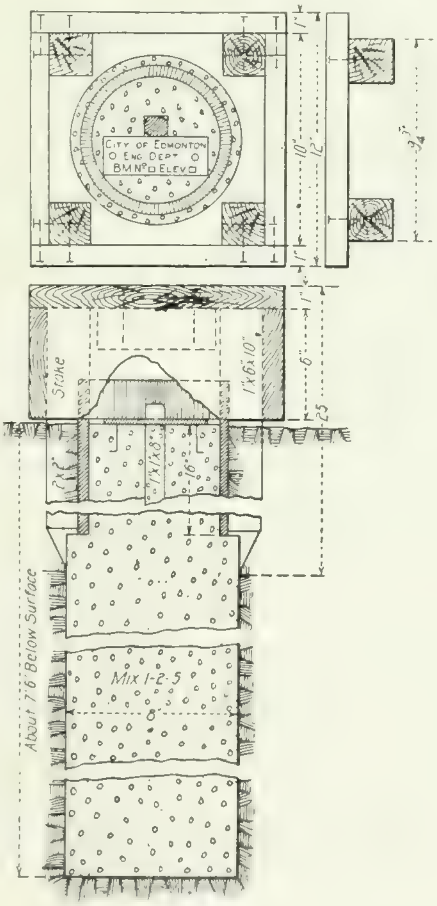

Fig. 1.

In view of these facts it was thought advisable, in the spring of 1911, to lay the basis for a complete new system. As the city is crossed and recrossed with railways, it was decided to place this system along the right-of-way of the different railways, each bench-mark being about one-half mile apart. Upon the advise from the railway engineers they were located two feet from the boundary of the right-of-way as the position least liable to be disturbed.

These bench-marks were made by boring an eight-inch hole seven feet six inches below the general ground elevation and refilling with concrete. The last eighteen inches of concrete was placed in a piece of six-inch cast-iron water pipe, which acted as a casing, and allowed the top of the bench-mark to be raised six inches out of the ground. In the top of the concrete was placed a square brass bolt, 1 x 1 x 8 inches long, and a brass number plate, as shown on Fig. 1. The bench-mark was then covered with a wooden box, made with four pointed legs, that were driven down over it.

In establishing the levels in this main system the original elevation was taken from the top of the brass bolt in the corner of the Bank of Nova Scotia, this elevation being transferred from the stone ledge above it, which had been taken as the first bench-mark in the city. From there levels were carried to bench-mark No. 1, and hence around the system.

In carrying the levels two rods were used with each instrument, and by cross-reading two turning points were obtained for each set-up. The ground was covered three times, and an average of the six elevations taken. The closing error in approximately thirteen miles was 0.06 of a foot, this error being distributed proportionately to the distance from bench-mark No. 1. This formed the outline of a rectangular system, having its longest sides above two miles apart.

From this main system secondary bench-marks are run out to cover the entire area within the city limits. The secondary bench-marks are of three kinds: those used in undeveloped and outlying districts; those constructed in boulevard or residential districts, and those constructed in business districts. In the outlying sections of the city it is found that a railway spike driven in a telegraph or electric light pole makes a good bench-mark. The pole may be painted white underneath the spike and the elevation painted on in red.

For residential districts a bench-mark similar to the main system is placed in the parking of the boulevard, and is located out from the corner of the block so that it may be seen from different directions. In some localities it may be desirable to use the cast-iron cover instead of the wooden box.

In business districts, where the entire area is covered with sidewalks or roadway, we are locating bench-marks in the sidewalk area, at a corner along a property line, and three feet back from the curb face. The construction, which is shown in Fig. 2, is similar to that used in the main system, except that it is fitted with a cast-iron cap that locks into the iron casing. This cap is brought flush with the sidewalk level. By placing this bench-mark three feet back from the curb face it is out of the way of telephone or electric light conduits, and may be seen from four ways on intersecting streets. Where possible, those bench-marks established on buildings which have had time to settle and those of the earlier systems are used as secondaries.

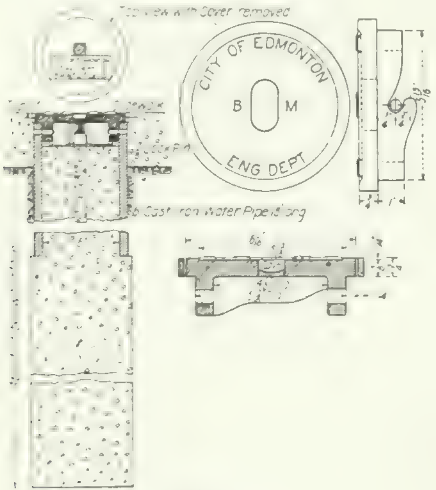

Fig. 2.

The city has now a belt line of bench-marks running two miles apart throughout the length of the city. The elevations, as shown by the closing error, are nearly perfect. From this belt line secondaries are run out a mile on each side. This gives a system of elevations distributed over the total area of the city that are as correct as it is possible to make them with an ordinary engineer's level.

◆

THE GRAND RIVER CONTROL.

The Ontario Government was approached on Wednesday, August [illegible], by a deputation representing the Grand River Improvement League. The deputation asked that a commission be appointed to investigate the conditions existing along the Grand River, and to recommend some method of improvement of conserving the water supply, prevent flood [illegible], and to [illegible] the advisability of instituting some plan of river control by a Board of Commissioners. The deputation was a large and influential one, representing [illegible] Mr. J. T. Jaffray, of Galt, [illegible] of the League, head of the committee. Mr. L. H. Breithaupt, M.L.A., C.E., presented the engineering aspects of the situation to the members of the Government.

[illegible] the different [illegible] were presented, Premier [illegible] expressed [illegible] sympathy with the movement and stated the Government would consider the [illegible] as [illegible] with regard to the entire province.

Mr. Breithaupt's argument is given in full herewith.

The Grand River from its source in Melancthon Township, Dufferin County, within twenty-four miles of Georgian Bay, to its outlet into Lake Erie, below Dunnville, has a length along its windings of approximately 140 miles. Its course is mainly southerly. Its drainage basin contains approximately 2,600 sq. miles, about one-sixth the area of the peninsula of south-western Ontario, and comprises nearly the whole of the Counties of Wellington, Waterloo and Brant and parts of Dufferin, Halton, Oxford, Wentworth, Norfolk and Haldimand. Tributaries of the Grand River are the Conestogo from the west, rising near the source of the main river, the Speed from the east, and the Nith from the west.

In topography South Western Ontario presents a high tableland, at elevation of from 1,400 to 1,700 ft. above sea level, near the northerly limit of the peninsula with slopes, abrupt toward the north and east, gradual toward the west, and at first steep, then gradual and becoming flat, toward the south-west and south, to the almost level rim of water of Georgian Bay and Lake Huron, with elevation of 581 ft. above sea level and Lake Erie, elevation 572. Its original condition was one of dense forestation. This has, except to small extent, disappeared, without, however, materially affecting precipitation, rainfall and snowfall, as shown by records extending over the past 60 years; the large surrounding bodies of water maintain humidity.

On or near the high table land rise practically all the larger rivers of the peninsula. Originally half or more of this headwater area was in dense swamp, excellent natural reservoirs for maintaining streamflow. During the past thirty to forty years these swamps have also been cleared and drained so that very little of them remains.

The great change that has come with deforestation of the country has been in the rate of run-off, of water precipitation, as shown in the flow of streams. Where formerly run-off was retarded and stream flow well sustained, the water now goes off rapidly, with the result that there are great floods at times of snow melting and floods after any heavy rain, with smaller stream beds dry and larger ones approaching that condition, during the dry months of the year.

The upper part of the Grand River, extending well into Waterloo County, and including the Conestogo tributary, is the part on which fluctuation of flow most largely depends. The drainage area of the upper river is at first flat and extended; further along it is steep.

High floods occur only once in the year, in the spring, with snow melting on the upper river. These floods have steadily become higher and the low water flow less. This year occurred the highest flood on record, in quantity of water discharge.

The prevention of damage by floods is to large extent practicable in many places by enlarging the regular waterway and by raising the banks by means of levees or dykes. This is well demonstrated on the Grand River by what the city of Brantford has done. Such control gives local relief only, and this is the only benefit. A method of control which benefits the whole river below where it is applied, and gives not only flood relief but also the great benefit of sustained flow, is of much greater advantage. Such a method is storage in sufficient quantity. Reforestation on a large enough scale to have proper effect would require so large an area as to render it of doubtful practicability on the Grand River.

The conditions determining requirement for storage are:

(a) The flood flow of the river;

(b) The amount of sustained flow, for low water period, that can be provided for.

The maximum flood discharges this year, obtained approximately at Elora, at St. Jacobs on the Conestogo, at Bridgeport, at Galt, and at Brantford, demonstrate that if a flow of 12,000 to 15,000 cub. ft. per second for 48 hours can be held, flood control is entirely practicable, and enough water can be stored to give a minimum flow of 400 to 500 cub. ft. per second throughout the low water period and therefore throughout the year.

The drainage area of the main river above Waterloo Township is approximately 460 sq. miles, and that of the Conestogo River to its outlet approximately 330 sq. miles. Precipitation on this area is indefinitely known; it is taken to be between 30 and 40 inches of water per annum. On run-off there are no data. It appears likely that the minimum run-off is not under 12 inches of the precipitation, and this for 600 sq. miles of drainage area would give sufficient water.

A dischargeable storage capacity of two and one half billion cubic ft. would be ample to effect the desired purpose. This would mean an area of 5 sq. miles with 18 ft. average depth. It could be in several separate basins. The first thing to be ascertained is whether the topography of the river valley offers suitable basins and in location with enough contributary drainage area. There are various sites that appear to be well adapted.

The minimum summer flow on the lower part of the upper river (from a drainage area of more than 800 sq. miles) has been under 40 cub. ft. per second, while the maximum flood flow this spring at the same place was approximately 24,000 cub. ft. sec.; the low water flow one-sixth of one per cent. of the maximum flood flow.

A sustained flow of 400 to 500 cub. ft. sec. would mean a gain of 4,000 to over 5,000 h.p. on existing water power developments on the lower river alone and there would in addition be large available horse power, below the range of lowest level, at the storage basins. The gain in water supply, sanitation, and general benefit, due to well sustained flow of the river would be inestimable.

GRAPHITE MINING IN CEYLON.

An interesting account of the methods of mining graphite in Ceylon, the largest producer of this useful mineral, is contained in an advance chapter on graphite by Edson S. Bastin, of the United States Geological Survey, from "Mineral Resources" for 1911. The graphite is mined either from open pits or through vertical shafts connecting with underground workings. Most of the mines are not deeper than 100 feet, though a few go as deep as 400 or 500 feet. In a few mines steam pumps and hoists are employed, but as a rule the mining methods are still crude, the acme of mechanical ingenuity being reached in a windlass operated by five or six men for hoisting the graphite in a sort of tub. The workmen usually ascend and descend by means of rough wooden ladders, tied with jungle ropes, and rendered exceedingly slippery by the graphite dust and water.

The mineral as it comes from the pits is conveyed in bags to a dressing shed, where it is picked over and the impurities reduced to 5 or 10 per cent. It is then packed in barrels for transportation to Colombo or Galle. At these ports it is unpacked and submitted to further treatment known as "curing." The graphite merchants have fenced yards or "compounds" for the final preparation of the graphite for the market. The large lumps and the screened pieces are broken with small hatchets by Singhalese women to remove the coarser impurities, such as quartz, and are then rubbed by hand on a piece of wet burlap, and finally on a piece of screening to give them a polish. Finally, various grades coming from several mines or differing in size or texture are blended to meet the requirements of purchasers.

The poor material is usually beaten to a powder with wooden mauls or with beaters shaped like a rolling pin and is then sorted into different grades.

One of the most important uses of graphite is for lubricating. The addition of graphite to oil results in a lower frictional resistance than would be obtained by the use of oil alone. The quantity of oil required for a given service is also reduced and a lighter grade of oil may be employed without decreasing the quality of the lubrication. A small quantity of graphite only is required, and the benefits derived from its use persist long after the application has ceased. Both the amorphous and the crystalline varieties of natural graphite are extensively employed for lubrication.

The use of graphite in the manufacture of pencils is probably both its oldest and its best-known application. This industry in Germany and England is several centuries old, and many of the modern factories manufacture hundreds of varieties of pencils, yet the percentage of graphite used for this purpose is not large, being undoubtedly less than 10 per cent. of the world's production, and one authority estimates it as low as 4 per cent.

The manufacture of artificial graphite is conducted by means of the electric furnace, an anthracite coal carrying small amounts of evenly distributed impurities being the material from which the ordinary grades are made. For obtaining the purest grades of graphite, petroleum coke is substituted for anthracite. The process for the manufacture of graphite was patented in 1896 and its commercial development has been so rapid that at present the output of artificial graphite in the United States is greater than the whole domestic production of natural crystalline graphite.

WOOD PAVING BLOCKS.

Consequent upon several articles appearing in the Weekly Report of the Department of Trade and Commerce relating to the opening in Great Britain for Canadian wood paving blocks, the commissioner interviewed the Secretary of the Highways and Paving Department of the Manchester Corporation, and the following information was obtained, viz.:—

"The area of wood block paving laid in public streets in Manchester is 37,634 square yards.

"Nearly the whole of the above paving is laid with Australian hardwood, Karri and Jarrah; the remainder is creosoted English beech.

"Wood paving is not considered suitable to the traffic of Manchester, and team owners strongly object to it. It is a costly pavement to lay and maintain and in consequence of these objections it has been laid only in front of public institutions (hospitals, schools, &c.) and in places where applicants have paid the cost of laying it.

"There is no prospect of an increasing trade in Manchester. The sizes of blocks used are 3 inches wide, 8 inches or 9 inches long, and 4 inches or 5 inches deep for Australian hardwood, and 6 inches deep for beech. The Australian blocks are not specially treated, but the beech is creosoted.

"A new length of wood pavement, requiring about 50,000 blocks, is about to be laid opposite a school, and creosoted deal blocks 3 inches wide, 8 inches long and 5 inches deep are specified for the work. The blocks will probably be Baltic timber, and the creosoting will be carried out at the place where the blocks are sawn, i.e., probably at the port of entry.

"Prices for delivered into Manchester vary from £6 to £8 10s. per thousand blocks, i.e., deal blocks."

STREET CLEANING AND REFUSE DISPOSAL.*

By F. W. W. Doans, City Engineer, Halifax, N.S.

In this [illegible] it is admitted generally that sanitary science and public health have made such rapid progress as to become a part of the order of every careful person's life.

Public health and sanitary science have many and varied phases of approach. The medical officer keenly dissects from week to week the vital statistics of his district, for by so doing, he is enabled to discover the cause of death and disease, together with the locality where such are especially prevalent.

The measure of success which the sanitary inspector meets in the performance of his detailed work among the people often ranks with the diligence with which he applies preventive measures. "Prevention is better than cure," and the most eminent scientists and medical men of the day are ever striving not only to "cure" disease but to educate the community in the best methods which may be applied to "prevent" disease.

When disaster overtakes a citizen through a defective sidewalk, street or sewer, woe to the official who knowing of the defect, failed to remove the danger. His negligence will cost the town many dollars and may cost him his position, and his family bread and butter. Nay, more, it may cost a human life. Is not the man equally negligent who, knowing the danger to the health of his fellow-citizen and knowing also how that danger may be removed, makes no effort to give his fellow-man the benefit of his knowledge.

The foundation and the most important feature of sanitary science, is "scavenging." Sewers and water supply are secondary considerations if scavenging is neglected.

During the last century, our cities and towns have become congested areas, densely populated, and each producing a vast amount of filth in its midst. Irrespective of the many perhaps at present unavoidable unsanitary areas in almost every city and many towns, there will always remain to be dealt with the natural filth products from the population and business connected with all cities and towns.

It is because of this latter factor more especially, that within the last quarter of the century there has been brought to the front that great preventive science for the suppression of the cause of diseases, "scavenging," as applied through the machinery of a scavenging department under the control of a superintendent with scientific knowledge.

A few years ago this department was created in some of the larger cities when it was regarded as a luxury, but to-day the smallest town realizes that something similar is an absolute necessity. Why? Because it has become recognized generally that filth and noxious refuse in or around the centres of communities has more to do with the creation of disease than any other one [illegible]. Each town has [illegible]

[illegible]

The people who are tied to the town and more especially the slum area, have neither time nor thought for public or even personal health. The insanitary conditions of their district and its surroundings have become second nature to them, and if they think of them at all, they resign themselves to the conclusion that it is a penalty attached to their station in life, and must be endured.

It is here that scavenging can work wonders. This science properly applied, cleanses the streets, purifies the air these people breathe, the houses they live in, the shops they work in and the yards and recreation grounds (too often the streets) their children play in.

The principal that should control every scavenging department is to provide such measures as will enable it to get in touch with all the filth and refuse as soon as it is created and to keep hold of it until it is permanently destroyed. This immediate action will lessen the danger of it becoming disseminated. Dirt and refuse upon the roads, streets, or in the back yards of dwellings cannot be said to be under effective subjection. It is so only when it has been collected, stored in some suitable receptacles (whether it be a garbage cart or a sewer) and is on its way to final sanitary disposal.

There is no section of municipal work under the public eye so persistently as that of street cleaning. The public watch every movement and are prompt in lodging their complaints. The work is one which deals wholly with dirt in one form or another, and is always objectionable and an ever-present asset to the fault-finding taxpayer. Sometimes the objector has good grounds for complaint, consequently the object of any system of cleaning should be to remove the cause as rapidly as possible and with the least amount of inconvenience to the citizen. The object of street cleaning should not be to obtain a favorable appearance only, but to insure sanitary conditions.

Street sweepings consist of the waste products of hundreds and thousands of human beings and animals and include the constant wastes that are being thrown off by the industries in our midst, the debris caused by the wear and tear upon the road surfaces, the dust and dirt from the pulling down or repair of buildings, soot and fine ashes from hundreds, perhaps thousands of chimneys, twigs, bark, and leaves from trees, pollen seeds and spores of plants, the expectoration from human beings, the excrement and urine of dogs and horses, and the leakage of the contents of loaded vehicles both in transit and while loading and unloading.

Even the scavengers add very materially to the filth of a town. The horses contribute droppings and urine and the carts are sometimes so imperfectly suited to the duty they have to perform, as to distribute in part the filth they are supposed to collect.

The streets of a town are the avenues over which its produced filth has to be carried and each receptacle deposits its quota on the road as it journeys through.

Shopkeepers sweep out their collection of dust and dirt and housekeepers shake their mats on the highway to make a further addition to the miscellaneous accumulation of filth that finds its way into the streets and pollutes the air. This custom should be prohibited and each such offender should be obliged to dispose of refuse in such a way as will not menace the health of his neighbor.

If the public were only educated in these things and taught what not to do, many lives might be brightened and lengthened. As conditions now prevail we inhale particles of filth which are being continually stirred up by passing traffic. Our food and even the liquids we drink are affected by [illegible] of these street filth, that it [illegible] our clothes and [illegible] blackens our buildings and doubtless tends to lower vitality.

---

*Paper read before the Union of [illegible] Municipalities, [illegible].

Now what do we do with this filth? The custom in most towns has been to use it to fill up low places in streets and sidewalks in the suburbs, and low ground elsewhere. It is absolutely necessary that stringent regulations should be made and carried out under which street sweepings should not be deposited on roadways or sidewalks to make a wearing surface. On the roadway, passing wheels fling its fine particles into the face of pedestrians and from the sidewalk it is carried on hundreds of boots into the home. It should be used at finished grade only for the boulevard part of the sidewalk and should be covered with a thin coat of good soil and sown or sodded as soon as possible after it is deposited. On the travelled part of the road or sidewalk it should never be deposited except to fill up below grade and then only when it can be covered with good clean material. In all towns there are streets which require thousands of loads to fill them up to passable condition. Thousands more may be disposed of on the town property and when such town places of deposit are exhausted there are many private properties on which there is low ground to be filled up.

The deposits removed from the catchpits should be used exclusively for the redemption of waste land, but no such disposal of catchpit or street cleanings should be permitted except by permit from the local health authority. A record should be kept of such dumping grounds. The date and character of the deposit should be recorded and no permit should be given for the erection of a building on such made ground until the health authorities are satisfied that nature has rendered the foul matter harmless.

In Halifax for some years the ashes collected by the city scavengers have been used to fill up low places in streets and sidewalks. Recently nearly all such available material has been utilized for sidewalk repairs except that in the summer it is used as a frost cushion under concrete sidewalks. During the past year the City Health Board has protested against this practice, on the ground that outbreaks of such diseases as scarlet fever and diphtheria have been caused by it. Whether or not their contention is correct, I am not prepared to express an opinion to-day, but it cannot be denied that the danger is possible.

It is claimed that householders empty sweepings into the ashpan and not into the stove. Although this is done in violation of the regulations of the Health Board, it is by no means an easy matter to prevent it. Frequently the kitchen maid finds it much more convenient to empty the dustpan into the ashes than to remove for that purpose the pots and kettles that cover the fire. The dust and dirt particles which may include the scarlet fever carrier, pass under the scavenger's eye without detection and consequently the regulation prohibiting the removal of ashes mixed with any other matters fails to protect.

Another objection urged is that householders expectorate in the ashes. I must confess that I have not been convinced that this practice is so dangerous as the deposit of sweepings, yet while there is any danger it should not be defended. It is not desirable to encourage such a custom, yet next to the fire, the best spitoon for any householder who cannot afford a cuspidor, is the ashes.

By the time the ashes are turned out of the pan into the barrel, turned out of the barrel into the cart and turned out of the cart on the place of deposit, the sputum is well covered with ashes and is not such a menace to health as it is when deposited on the dry impervious pavements where it can dry up and blown about. The ashes contain carbon, charcoal and recalcined lime which are deodorants and disinfectants. It is doubtful, however, if the natural process of humification becomes active in ashes as soon as deposited.

The natural soil is primarily derived from the subsoil which may itself be regarded as the weathered portion of the underlying soft or hard strata. Science has taught us that the upper layers of the soil are teeming with forms of or-organic life whose hunger is inexhaustible and whose power of absorption is so active that anything that is even thrown on the surface of the ground speedily disappears, and whether animal or vegetable, becomes humified and so incorporated with the soil as to become actually indistinguishable from it.

In time the objectionable matter in the ashes would undoubtedly be reconstituted into harmless mould by the action of micro-organisms and earth worms. The doubt, however, respecting what may happen in the meantime, prohibits us from defending the general use of such ashes in repairing sidewalks in the neighborhood of residences. "Separation of ashes from all other refuse under whatever system of collection, is always more or less imperfect and incomplete. Some house or store dirt will find its way into the receptacle intended only for ashes, and house dirt is peculiarly exposed to infection and is doubtless often really infected dirt. Hence it follows that not even ashes can be regarded as certainly free from infection, while garbage must be recognized as peculiarly exposed to it. There is one class of ashes which is so little exposed to infection as to belong in a group by itself, and that is the ashes from factories and other large establishments into which food does not enter.

It would be safer to dispose of the house ashes in the same manner as suggested for street sweepings and the same precautions should be taken by the health authorities respecting buildings on such deposits.

The best method of disposing of the house garbage cannot be determined so readily. A brief statement of the problem with an outline of general methods adopted for its solution may be of timely interest.

In Minneapolis the citizens are required to drain off all moisture from garbage and to wrap the solid in paper before putting it in the garbage barrel or can. If the collector reports to the scavenging department that the garbage is not properly drained and wrapped in paper no further service is rendered until the rule is complied with. If the householder then fails to care properly for his garbage or have it cleaned up, he is brought into court and fined.

It is claimed that the drained garbage will neither smell badly in hot weather nor freeze and stick to the can in cold weather.

Under existing conditions in almost every town, the can or the barrel is frequently a greater nuisance than the garbage itself. In primitive days, the Indian when the offence from the waste product of his house-keeping became too noisome, moved away, but in our day and generation we remove the garbage and keep the odor. With the presence of heat, moisture and flies, garbage very soon becomes a foul, maggotty, fly-breeding mass of putrefaction.

In the humble opinion of the writer, the Minneapolis regulation is admirable, although it may be a half measure only. A by-law requiring the draining of garbage is a good regulation but only half as good as it would be if it provided for burning in the kitchen fire after draining.

At a house in Halifax, which I visit frequently, although it has been occupied for over a dozen years, not one ounce of kitchen garbage has been removed from the premises by the city. All garbage and other combustible refuse is burned in the kitchen stove, the burning being carried out when there is a good bright fire. A removable strainer basket is kept in the corner of the kitchen sink. It costs 50c. and will last for years.

Peelings, the scrapings of plates from the table, porridge, soup or vegetable pots, pans, &c., leaves from the teapot, solids in the dishwater after washing, all go into the strainer in turn, and shortly afterwards into the fire. Fat skimmed from soup, gravy, &c., is cooled in a cup or saucer and then burned. Bones meet the same fate. There has never been a garbage can about the premises nor has one been needed. The only refuse which requires removal is bottles and cans.

As a result of practical experience, therefore, it is claimed that a by-law compelling householders not only to drain their kitchen garbage but to burn it, would be a great improvement on the draining alone.

It would not be a panacea, however, for all garbage ills. In summer, especially, in some houses the cooking is done on oil or gas stoves. Hotels and boarding houses have too large a quantity of garbage to burn, while some means must be provided for disposing of the garbage from grocery, provision, fruit, meat and fish stores, and many other properties where there are no fires in summer.

The most important part of this problem which we are called upon to solve is the method of final disposal. When a town has advanced sufficiently in population and public spirit to warrant a co-operative effort to handle and dispose of its household waste, the method of disposition invariably adopted in the first place is to gather all the refuse which would create a nuisance and be a menace to health at the individual residences and haul it all to one spot where it is dumped. It will be admitted readily that this method although so widely used, does not really dispose of the nuisance. It simply changes its location, and as the town extends, new dumping sites have to be found, with the added expense of a longer haul in order to place the danger at a more or less safe distance. It is questionable, however, whether there is any safe distance within cartage limits of a town.

With our present day knowledge of the causes and dissemination of disease, two minutes thinking should convince anyone that to collect decaying and putrid vegetable and animal matter and spread it out in the open atmosphere is unsafe, insanitary and unscientific.

A visit to a refuse dump will show it to be a breeding place for flies, rats, etc., and a source of offensive unwholesome odors, which are carried by the wind for long distances. Flies from such a place may be expected to carry disease into any residence they may enter. The danger to public health is further increased by the sorting over of the refuse by men and women and boys, who find articles which they consider of value. The fact that these articles have been in contact for hours, perhaps days, with the mixed refuse and garbage, together with the fact that the articles are not likely to be free from filth and disease germs themselves, [illegible] the risk of [illegible] these [illegible] back again to the [illegible] of dirt and disease germs.

The [illegible] and refuse in a manner conforming to sanitary law, is becoming a matter of vital importance and should receive the immediate attention which so important a factor in the welfare of the town deserves. It is most essential that adequate means be provided for the efficient disposal of all decomposing refuse, including dead animals and night soil. Sanitary authorities agree that the complete destruction of garbage or a complete change in its characteristics is the only solution that will satisfy sanitary [illegible].

[illegible] which [illegible] the reduction [illegible].

[illegible]

The reduction method which consists of passing the garbage only, through a digestive process and extracting its oils and grease, is not popular for the following reasons, namely, that it is expensive to install, it is very difficult to carry on the process without causing a nuisance by offensive odors, it deals only with the garbage, and some other means must be provided for disposing of the night soil and remaining refuse. Separate collections must be made and the town must compete in the open market to sell its grease and tankage. In a few towns night soil is disposed of by dumping into large intercepting sewers. It must be done in an enclosed chamber and under town supervision. The location must be chosen where an abundant supply of water is available and the carts used should be of the latest design.

The most successful means of disposing of town wastes is by incineration.

Furnaces are in use to-day in many towns having a population of only a few thousands and are solving the refuse disposal problem satisfactorily and economically. Time will not permit a description of the method employed.

Inquiries from Windsor and other members of the Union prompted me to prepare the foregoing information in the hope that it might make investigation easier for municipal officials who are convinced of the necessity for some improved method of refuse disposal.

FOREST RESOURCES AND MILLS OF NEWFOUNDLAND.

Reporting on conditions in Newfoundland, United States Consul James S. Benedict, of St. Johns, says of the forest resources and growth of the paper mills during 1911:—

"The resources of the forests are a steadily increasing factor in the development of Newfoundland. During 1911 there were fifteen lumber mills working under license, and 271 fishermen's mills without a license. The latter are permitted by the Government to operate for the sole purpose of supplying the fishermen with material for the construction of their buildings, vessels, etc. The output of the mills for the season amounted to 53,187,000 feet, as against 45,000,000 feet for 1910. The pulp wood cut amounted to 100,000 cords, as against 30,000 cords during the previous year. The men employed in the woods numbered 3,715 and in the mills about 1,500. For the fiscal year 1911, 6,085,000 feet, valued at $125,270, were exported, as against 7,707,000 feet, valued at $144,666 for 1910. The export of laths amounted to 2,315,000 pieces, valued at $4,768, as against 4,868,000, valued at $9,646, for the previous year. The local building operations consumed the larger portion of the lumber and laths manufactured, and there is an increasing demand.

"The pulp and paper mills at Grand Falls and Bishops Falls got fairly under way, and the two companies exported 21,064 tons of news paper during the fiscal year 1911, valued at $[illegible], and [illegible] tons of pressed ground wood pulp, valued at $[illegible]. For the last six months of 1911 the export value of the products of the two mills amounted to $[illegible], and for the calendar year 1911 the estimated value of paper and pulp was placed at $2,250,000. The importance of the paper and pulp industries may be seen by the fact that the company at Grand Falls at present employs about [illegible] men in its mills and 100 to [illegible] more in loading vessels. The total wages paid amount to about $[illegible] a year, and the mills, with the new machines installed, are expected to have an annual output of at least [illegible] tons of ground wood pulp and about [illegible] tons of paper. The company at Bishops Falls also employs a large number of men in similar work. At present it is at work on the extension of the pulp-making plant, and further extension within a year is contemplated for the manufacture of various grades of paper."

REPORT ON RAIL CORRUGATION.*

By Arthur Busse, Chief Engineer of Way Grosse Berliner Strassenbahn.

The investigation into the cause of rail corrugation which has been continued by this association during the past two years has brought out a number of facts which have been more or less new, as well as opinions of many of the member companies on this subject. Some of these follow.

The Amsterdam Tramways believes that for a given composition of rail the length of the corrugations will depend on the speed of the cars. This opinion, however, is contrary to that enunciated by this committee in its last report that the metal of the rails itself contains the germ which gives rise to rail corrugation. Moreover, we believe that such a theory would be difficult to sustain. In our reports of 1906, 1908 and 1910 we showed that corrugations on a railway over which cars were run at the same speed varied in length when measured at two neighboring points. These measurements were taken not only on straight track, but also at stops and stations. There was no relation between the length of the corrugations and the speed of the cars.

The Antwerp General Tramway Company has observed small corrugations on the heads of new rails, but it does not consider that these are sufficient to start real rail corrugation, and has found that after a short period of service they disappear and the surface of the rail in contact with the wheel becomes polished. It does not believe that the method of rolling causes corrugation. Thus it calls attention to the development of corrugations in cast-steel special work, even in cast manganese-steel frogs, as noticed by other companies, although such material never passes through a rolling mill. In this connection the committee might add that such corrugation has been noted in Berlin in a section of cast-steel rail laid in an experimental track by the Berlin Tramways. The depressions were slight, but were visible, and their origin, in the opinion of the committee, is attributable to the method of manufacture. Manganese steel in track is not immune from corrugation, as shown by the experience of the Berlin Elevated Railway. In Antwerp the company report that the rails most corrugated are those on the outside of long curves and grades. The corrugations on the up grades are spaced 7 cm. (2.8 in.) apart and on the down grades 11 cm. (4.4 in.) apart, whereas on straight track the spacing is usually 9 cm. (3.6 in.). For this reason the company does not think that the incipient cause of corrugation exists in the rail before it is put in service. The committee, however, does not agree with the company in this conclusion, because if the active agent for developing this incipient corrugation is the sliding of the wheels the different lengths on up grades and down grades can easily be explained. Those on the down grade should be longer and those on the up grade shorter than those on level track, and the average should be about half way between the two, as shown in Antwerp.

Another company in Berlin, the Antwerp Tramway Company, is inclined to adopt the theory that corrugation is the result of a cold rolling of the rails by the wheels, according to a theory advanced by Mr. Beaumont in Engineering for September 8th, 1911, but differs with the conclusions of that gentleman in believing that the movement of the metal in the head of the rail is toward the sides of the rail, and is checked on the inside only by the pressure of the wheel flange. This checking force is not continuous, but intermittent, as the flange strikes against the side of the rail, and the effect of these two forces, one vertical and one horizontal, is to produce nodes.

The Bamberg Electric Tramway Company has found corrugations in light sections of rail, but not in heavy sections, and thinks that the light rail is too light. But, as the committee has already shown on other roads, corrugations occur on certain sections of rails, but not in others of exactly the same section when both are exposed to the same traffic conditions.

The Bern Municipal Tramways reports that corrugation developed in track laid on a bridge on a base of concrete. In 1906 a wood flooring 3 cm. (1.2 in.) thick was placed between the rails and the concrete for a distance of 60 m. (200 ft.). Since that time there has been no corrugation on this section, although elsewhere on the bridge the rails have become badly corrugated. The management believes that an elastic roadbed will reduce the trouble.

The Berninabahn, in Switzerland, which believes the process of rolling to be the initial cause, cites among other interesting facts that a part of its system some time ago was operated by steam, and the rails on straight track of this steam road developed corrugations. Later, this line was equipped electrically, and during the past three years there has been no change in the conditions either for good or bad. Later, some new rails were installed in a part of the line on which no corrugations had previously formed, but they developed the trouble.

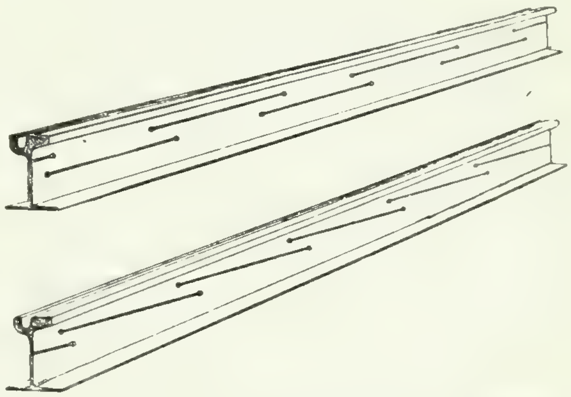

Fig. 1.—Rail with Slotted Web, Used in Cöteborg.

The Municipal Tramways of Dresden has conducted a number of experiments, and is of the belief that corrugation is due essentially to the sliding of the wheels, although it may have had its origin in the method of rolling. In some recent track it laid alternate sections of hard and soft rail, the hard rail with an ultimate resistance to tension of 80 kg. per sq. mm. (114,000 lbs. per sq. in.), and the soft rail of 67 kg. per sq. mm. (95,000 lbs. per sq. in.). Corrugations appeared without an appreciable difference in both kinds of rail. It had been able, however, to reduce corrugations by laying rails on wooden ties. The conclusions of the Dresden company correspond with those of the committee, which, in its reports of 1906, 1908 and 1910, held sliding of the wheels to be one of the causes of corrugation, but expressed the belief that the initial cause was to be found in the method of rolling. The report from Dresden also tends to show that low-carbon rails, when used with low-carbon wheel tires, wear less rapidly than high-carbon rails with high-carbon tires. The Dresden company also found corrugation in its overhead trolley wire, which is of silicon bronze, confirming previous observations made by the committee.

---

* Abstract of a report submitted at the biennial convention of the International Street and Interurban Railway Association, Christiania, Norway, July 2nd to 5th, 1912, and recently published in the Electric Railway Journal.

The Geneva Tramway Company has experienced trouble with corrugation in the Phœnix 18-C rail, but not in the Phœnix 5-F rail or in a T-rail. The 18-C rail was generally laid in concrete and the T-rails are on wooden ties. The corrugations did not appear on steep grades, but on level track and slight grades. The committee thinks that the difference in corrugation between the 18-C rail and the 5-F rail may have been due to their difference in height and method of support, and its absence in T-rail to the different method of rolling this section.

The Göteborg Railway had experienced corrugation not only in rails, but in special work which is not rolled. It has also tried in experimental service some rails with slotted webs, as shown in Fig. 1, finding that corrugations disappeared in rails so treated. It believes that the corrugations observed on new rails have the same origin as those corrugations developed in service; that is, that the former are caused by the chattering of the rolls, and the latter by the vibratory wear of the wheels, but that the car wheels alone will produce corrugations, even on rails not initially so predisposed, and that the remedy is an elastic construction. The committee adds that the Berlin Tramways noticed some four years ago that very low rails do not seem to become corrugated. In consequence, it has, as an experiment, laid a section of track with a rail only 100 mm. (4 in.) in height. This rail is mounted in a concrete block. The experience with this section of rail, so far as absence of corrugation is concerned, has been so satisfactory that the company is planning to adopt a modified type of elastic rail, which it is working out in detail. The experience of the Berlin company indicates positively that the corrugations may be attributed initially to the method of rail manufacture, and that light and elastic sections are less subject to the trouble, and are often exempt from it.

The Leipzig Tramways reports that grooved rail mounted on concrete or stone ballast is rapidly attacked, and T-rails on wooden ties on stone ballast are entirely exempt.

The Hamburg Tramways Company attributes the difficulty principally to the method of rolling. The tendency to corrugation is increased (1) when the number of passes at the mill is large, but especially during the formation of the groove, when the change in shape of the metal is rapid, and also (2) when the tensile strength of the metal in the rail is high and the modulus of elasticity is small. The committee adds that its views coincide exactly with those enunciated.

The North Side Holland Traction Company lays stress on the necessity for elastic foundations. It notes that there is necessarily some slipping of wheels on the rails, both when they pass around a curve, and even when they move on a straight track, on account of the nosing of the cars. This slipping causes a vibration, which is transmitted by [illegible] and the company thinks that it is this varying pressure between the rail and the wheel which causes corrugation. An elastic track is better [illegible] in the present conclusions of the committee.

The Christiania Electric Tramways proposes to experiment with the [illegible] rail now being tried in [illegible].

[illegible] the opinion that corrugation is due to the method of rolling [illegible]

be made to overcome the differences in temperature existing between the different points of the same billet and the differences in pressure during the eleven or twelve passages which the wheel makes in the mill.

The Nuremberg Tramways states that on its system the rails which have been corrugated and afterward carefully ground down have developed other corrugations without exception, but in places different from those embodied by the first. It has found corrugations in T-rails as well as in grooved rails, but a longer time is required to develop corrugations in T-rails. In cases which are not favorable to the production of corrugation, such as short-radius curves and low speed, the initial corrugations have disappeared at the end of about three to six months. Light rails resting upon a basis of sand are immune, but heavy rails, even those rolled in the same way as the light rails and of the same metal, have been attacked. The corrugation has been particularly rapid in rails laid in a bed of sand on a foundation of ballast. Hence it does not appear that it can be avoided, even with an elastic foundation.

The Shanghai Tramway Company, China, has part of its system laid on ties with stone ballast, the other part on concrete. The former section has shown but slight corrugation and the latter a great deal, although the rails were secured from the same mill and rolled at the same time.

Edgar Rhodes, New York, calls attention to the Romopac duplex rail, which has not been attacked in Leeds, England, although ordinary rails under similar conditions have become corrugated.

Discussion by the Committee.—The committee in considering these reports says that in general they accord very closely with the opinions published in previous reports and the conclusions reached in other years by the committee. These conclusions were briefly that the factors causing corrugation were:—

(1) The quality of the rail. (Recent observations indicate that this is the principal cause of corrugation.)

(2) The use of hard tires.

(3) Too rapid braking at high speeds.

(4) Too rapid acceleration.

(5) Too high speeds.

(6) Nosing or side oscillation of the car, which can be produced by (a) the usual rigid mounting of two wheels on the same axle; (b) unequal diameters of the two wheels on the same axle; (c) difference in elevation of the two rails in the same track; (d) unequal division of the weight; (e) variations in resilience of the different springs of the same car; (f) play in the journal boxes; (g) irregularity in the gauge of the wheels; (h) irregularities in the surfacing of the track; (i) effect of torsion and distortion due to the method of driving the axle at one side; (j) axles out of square; (k) bad construction of the car; (l) too short wheel base.

(7) Large radius curves.

(8) Character of track substructure.

In the opinion of most of the companies of the association the nature of the metal in the rails (No. 1) is considered as the principal cause for corrugation, and the points mentioned under Nos. 2 to 8 favor the development of corrugation, but do not cause it. Many experiments have shown this. Thus, rail bought from different manufacturers, or from the same manufacturer, but rolled at different times, were laid without any particular order on the same trunk line, so that the operating conditions were the same, but it was found that their wear was entirely different. Those from one manufacturer or from one rolling showed a marked corrugation, whereas those from other manufacturers or from different rollings were not attacked. The railway companies and the manufacturers are equally interested in endeavoring to find a metal which will resist the wear.

Several years ago at the meeting of the Iron and Steel Institute of Great Britain Thomas Andrews called attention to the quality of metal in the rails. His analysis showed that there was often considerable free carbon, sulphur and phosphorus at certain points, and that this condition would not have occurred if the ingots had been allowed to stay longer in the annealing pits before rolling.

Mr. Peterson, manager of the Municipal Tramways of Dortmund, who has made an exhaustive study of this subject, has reached the opinion that conditions inherent in the process of manufacture, such as the rolling of the rail at too low a temperature and insufficient malleability of the ingot during the rolling, are the cause of the trouble.

An interesting discussion in Stahl and Eisen for March 7th, 1912, also appeared, by Karl Neu, on observations upon steel ingots during rolling. These observations are especially remarkable, as they contradict the general opinion on the processes of cooling of steel ingots. They were made on ingots, some of which had remained in the soaking-pit the usual length of time, and on others which had been in the soaking-pit for an abnormally short length of time only. In one case an ingot weighing 1,800 kg. (3,960 lbs.) was first cooled in the ordinary manner, and then placed in a reheating furnace, since no soaking-pit was available. The ingot was taken out after seventeen minutes and rolled down to a cross-section of 170 mm. to 200 mm. (7 in. to 8 in.). A notable thing was that after the first passes the ingot presented an expansion at the middle. While according to laws of solidification the metal should be purest on the outside and the largest cavities should develop in the interior, the opposite was found to be the case. A second ingot, 2,010 kg. (4,420 lbs.) in weight and 450 mm. x 450 mm. (18 in. x 18 in.) in section, was allowed to remain fifteen minutes in a pit which was not heated. Then it was rolled down in twenty-five passes to a section 175 mm. x 220 mm. (7 in. x 8.4 in.). Here again there was produced an enlargement which resulted after the third pass in a split forming in the direction of the rolling, and liquid steel ran out of the crack. The explanation suggested by Mr. Neu is as follows: When the central part of the ingot is still in a fluid condition before rolling it is naturally predisposed to be occupied by the impurities, although the exterior or that already solidified presents a great degree of purity. When rolled too soon the plastic material in the centre is forced into the outer parts of the ingot. This suggested to the author the desirability of leaving the ingot in the pit longer so as to improve the quality of the metal.

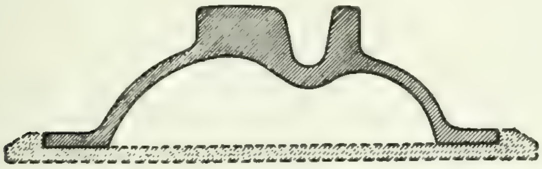

Fig. 2.—Rail with Double Web Being Tried in Germany.

L. Potin, another recent contributor to Stahl and Eisen, states as the principal cause of corrugation a too high temperature of the material when the rolling is begun and irregularities in the manufacture of the rail. He points out that when a rail is being rolled there are many abrupt differences between the speed of travel of the rail and of the rolls. When this difference of travel is large there is the drawing of the metal from behind the roll and a wave of the metal in front of the roll similar to that which occurs on a canal upon the passage of a boat. This produces a series of waves in the rail, and these will be particularly noticeable in the rolling of the head, where the cooling has been most rapid. He suggests that the way to avoid this trouble is to include in the specifications a limiting temperature for the last pass.

Dr. Poppe, of Breslau, disagrees with these conclusions, and says that it is erroneous to believe that corrugation began to appear only at the time when the mills commenced to roll rails at a high temperature. He also says that the soft iron rails of previous years were rolled much warmer than the steel rails employed exclusively today. He points out that the "creepage," or difference of speed between the rails and the rolls in the mill is much greater when the temperature is low. Consequently, corrugation ought to be less when the rails are hot, and not greater. He thinks that the length of corrugations depends on the speed of the cars and their weight, and hence it is unnecessary to impose special specifications on the rail-makers. These ideas ought not to pass without protestation.

G. E. Pellissier, in an article in the Electric Railway Journal for September 30th, 1911, believes corrugation due to a crushing of the surface of the rail by the wheel, and seeks for improvement in a different form of head. But this theory can hardly be admitted. If it was a question simply of superficial pressure, there would not be a difference in corrugation between rails rolled at different times, as has been observed, nor would there be corrugation of third rails, as shown on the Elevated and Underground Road of Berlin. Moreover, photographs of corrugated rail show that the corrugation extends the entire way across the head of the rail.

An interesting discussion on methods of measuring rail wear has appeared in recent issues of the Zeitung des Vereines Deutscher Eisenbahnverwaltungen. Theoretically, the ability to stand wear is in direct relation to the resistance to abrasion of the steel. Practically, the tests given are shock and rupture tests. Several methods have been proposed actually to determine the ability to stand wear. One is by an abrasion machine operated by electricity, a measure to be taken of the electrical energy required to remove a certain amount of material. Another method is to subject the rail to a blast of sand, a plan which should give good results if a basis of comparison could be chosen. A third method is to measure the effect produced by the rolling and the sliding simultaneously of steel wheels on the rail.

There is no doubt that the mills ought to endeavor to produce a metal more uniform as regards structure, density and durability. Railway companies at the same time ought to turn their attention to means of lessening the rigidity of the track structure, such as by using lower rails or a more elastic roadbed. By this means only can the trouble be reduced. As already cited, the plan of the Berlin Tramways is to use a low rail, and that of the Göteborg Tramways is to use the roll with a slotted web. Another effort toward introducing elasticity in the rail, shown on this page, has recently been patented in Germany. It has a double web, and compared with the centre web rail presents the great advantage of being rolled in such a way that at each pass in the roll the head tends to become more dense.

Conclusions.—The conclusions reached by the committee this year are not greatly different from those of preceding years. Nevertheless, there is added evidence that the primitive cause of corrugation is the method of rolling. Great interest attaches also to the use of elastic rails.

Appendices.—The report contains two appendices, one a report of some tests made by Mr. Peterson, manager of the Dortmund Municipal Tramways, on rolling lead ingots. These showed marked corrugation after they came from the rolls. The second appendix is a paper on the subject of rail corrugation read by Messrs. Schwartz and Cunliffe before the Institute of Electrical Engineers at London, March 18th.

PROBLEMS OF ROAD CONSTRUCTION.*

By Major W. W. Crosby.†

Possibly the problems of organization, administration, planning and recording might easily be considered to be included under the title of this paper. But to attempt to consider properly all these items would require the writing of a book, and even to attempt to touch on all of them in the limited time available for the speaker, would require so hasty a skipping "from crag to crag" as to result in almost entire waste of effort on the part of both the speaker and yourselves. Consequently, the speaker conceives it to be best to confine his remarks to details of actual work, out on the job itself.

Generally speaking, the first operations are those of grading and of installing the underground structures, such as culverts, abutments for bridges and underdrains.

If any clearing or removing of trees and old stumps is to be done it should be done promptly and thoroughly. Where practicable, the removal of trees should be accomplished by cutting off the roots around the tree a little distance away from the trunk and then pulling the tree over so as to rip out the stump proper. The roots thus left in the ground will do no serious harm unless within a foot of the road surface. It is sometimes the practice of the speaker to allow trees to be cut off close to the ground and the stump to remain, provided that there is to be not less than two feet of new fill between the top of the stump and the bottom of the surfacing. It may be trite, but it is at least safe to remark that in no case should a foreign stump be allowed to be placed in any embankment.

Underground structures, especially those that cross the road, should almost always be started as early in the proceedings as practicable. Such procedure not only insures their being out of the way of the later work and gives more opportunity to conveniently handle the public traffic generally to be provided for over a road, but also allows more careful construction and better results in the backfill. Only too often serious defects and extra expenses occur in the surfacing over culverts too recently installed before covering them. In this connection, the speaker will state that it is his practice to use vitrified clay pipe for all culverts 12 ins. to 24 ins. in diameter where the covering over them is not less than 2 ft. in depth and concrete boxes or cast iron pipe where the headroom or cover is less. He has experimented in a very few instances with corrugated wrought iron culvert pipes, but is as yet unconvinced of their general desirability. In his experience, he has had no difficulty with the use of first-class vitrified clay pipe even under heavy fills of, say, 20 ft. or more. Above 24 ins., the speaker prefers what is called "double strength" if clay pipe is to be used, but generally concrete boxes would be cheaper. Of course in the use of clay pipe, care must be exercised in the laying and backfilling, especially to prevent the presence of anything like a stone nearer the pipe than, say, one foot. The speaker has seen a stone about the size of one's two fists forced by the fill above directly through the wall of an 18-in. clay pipe.

The bed on which a pipe culvert is to rest is a consideration frequently slighted. [illegible] allowed to [illegible] changes. This is of especial importance where [illegible] of pipe are used. A bed of sand or fine gravel on which to lay the pipe is often desirable and advantageous. Even oyster shells or crusher screenings may be used. The speaker had one case some ten years ago where a road crossed a bight of salt marsh by a pile trestle about 200 ft. long. It was proposed to fill in the space, instead of making the necessary renewal of the old wood work, and to care for a small stream crossing the road through the marsh by means of a double line of 30-in. cast iron pipe. The surface of the marsh was at about mean high tide and the marsh mud of unknown depth. Therefore, along the slight stream depression through the marsh, the speaker laid a bed of oyster shells—the cheapest available mineral material—about ten feet longer than the pipe and about 12 ft. in width. The shells were dumped from carts through the floor of the old bridge and spread out as necessary to probably an average depth of 2 ft. and with their upper surface level and just above high tide. The pipe was then laid on the centre of this bed and the filling over them placed. The results have been entirely satisfactory.

Especial attention to drainage is necessary in Maryland work owing to both the prevalence of loamy or clayey soils and to the "open" character of the winters. A great deal of "French drain" is used. The pipe is vitrified clay and generally 4 ins., though sometimes 6 ins. in diameter, with bell and spigot joints. Stone, gravel or shells may be used for backfilling with apparently equal results. We think it preferable to install the underdrain just ahead of the surfacing work in most cases.

Practically all pipe ends should be protected by masonry head walls as a matter of protection and economy, to say nothing of appearance. Generally our masonry is concrete on designs made in our own office. Flat slabs or girders, reinforced when necessary by twisted or corrugated steel rods, are usually sufficient. Occasionally, special circumstances warrant an unusual design. In such a case, bidders are given the opportunity to submit their offers with their own designs. These latter are checked by our office and the comparison made between the offer and the office plans and estimates so that a decision may be had.

Of course, the key to successful bridge work is in a proper foundation and this is a subject by itself. Not much more can be said here than that almost all kinds of foundations have their place and the real problem in each case is one of proper selection.

Preliminary to the placing of the surfacing comes the preparation of the roadway for it, or what is generally known as "subgrading." The speaker considers the matter of a proper subgrade one of the most important of all construction problems and regrets to be obliged to state that it seems to be one too often neglected. In his judgment more failures in the surfacing have had their rise in defects of the subgrade than in any other source. In fact, the importance of a proper subgrade can hardly be overestimated. A proper subgrade should be firm, even and as little susceptible to damage by water as possible. Gravel, preferably sandy or with no excess of clay, gives an ideal subgrade when properly shaped and rolled. Clean sand will furnish a most satisfactory one, though it may bring about some waste surfacing material. In many localities, neither sand nor gravel is available. Crusher screenings may be substituted with very satisfactory results. Some clays will make a very good subgrade, if not so wet as to be muddy or rubbery, nor so dry as to be dusty, provided the surfacing and underdrainage are so installed as to keep the clay in good condition. Other clays cannot be handled thus. The speaker has secured satisfactory results in some instances by the use of a layer of gravel, sand or screenings 4 ins. to 6 ins. thick immediately below the surfacing.

---

*Read before the American Road Builders' Association, [illegible]

†Chief Engineer, Maryland State Road Commission.

Also, rolling a layer of stone into the subgrade after shaping it but before applying the first course of the regular surfacing, frequently relieves the defects in the subgrade. Another way is to prepare the subgrade by shaping and rolling as usual and then applying a first course of the macadam of special composition. That is, instead of using for this course, one size of stone, to mix with the ordinary No. 1 stone, say 50 per cent. of sand or screenings (for instance by running the screenings and No. 1 together from the screen). Then spread this mixture on the prepared subgrade, harrow it, and then roll. This has proved a very satisfactory solution in many cases where otherwise the failure of ordinary 8-in. macadam was almost certain. Probably the fine material in the No. 1 stone prevented the coming up of the subgrade material into the macadam and thus its destruction in freezing and thawing wet weather.

In passing, the speaker wishes to state that he considers that this matter of subgrade is only too often neglected in city work where a concrete base is to be used under the surfacing proper. In many cases too much dependence is apparently placed on this concrete base and even unnecessary expense is had for such concrete when by proper attention to the subgrade beneath it, not only better results, but also much saving in cost, might be secured.

In the reconstruction of old roads, it frequently happens that but slight changes of grade are desirable. Many of these old roads, such as the "pikes" have been "stoned" in the past and so massively, but withal so crudely, that they now present to travel surfaces that are solid beds of stone (mostly large) whose unevenness and roughness furnish the main, if not the only, reason for their treatment. Many of the audience will recognize readily a statement from the speaker to the effect that those familiar with such an old road are hostile to any idea of digging into or removing the old roadbed, if only for the purpose of breaking up the large stone. Nevertheless such a procedure is often the economical thing. If it cannot be done for any reason and the old stone bed must be allowed to remain, then the grades for the finished surface must be properly adjusted so as to provide at least a minimum thickness of new surfacing on top of the high points of the old stone. And this minimum cannot successfully be less than 4 ins. in the case of water bound macadam. With proper care in bituminous work it can probably be reduced to 2 ins. and possibly in some cases to even less.

Further, in such work on an old road, the depressions to be removed present a problem. It will not do to fill them with an absorbent material like clay or loam, and filling them with surfacing stone may be necessary even if expensive. Frequently, however, a cheaper roadside stone of inferior quality will answer. The same remarks apply to thin layers of material to come between the old roadbed and the bottom of the new surfacing.

In what may seem perhaps to have been rather a cursory way, the speaker has at last reached the problems of surfacing. And here perhaps a breath should be taken in view of the vast outlook.

Are there anything but "problems" in the subject of surfacing? And what a wide field of them, a field yearly becoming wider and more diversified, thanks to the activity of the proverbial American ingenuity, offers itself! To discuss, or even to review, a list of all the problems in this field, would be beyond the bounds of the present conditions, so the speaker will, in closing, merely mention a few salient points under the various kinds of surfacing on which he has convictions, or to which he feels it might be proper to direct your attention.

With sand-clay surfaces, it is important to get an intimate, even, and properly proportioned mixture of the sand and clay. With unscreened gravel surfaces, it is necessary that the gravel be free from stones larger than, say, a goose egg, and from an excess of fine material, i.e., either sand or clay. It must have, however, sufficient "fines" to fill the voids of the gravel stones, and preferably these fines should be of a highly cementitious character. If too weak in cementing qualities naturally, then something such as pitch, must be added to make up for the lack of bond among the round gravel stones and thus to remedy their tendency toward displacement under traffic, especially in very wet or very dry weather.

With screened gravel surfaces, when the correction of the sizing is had by the screens, the same remarks then apply. In some cases, screened gravel may be satisfactorily "bound" with limestone screenings. With marl surfacing the problem is to secure the necessary uniformity of the material and then to properly compact it in place. Plentiful watering and rolling is important.

With broken stone macadam, in the experience of the speaker, the most necessary, and at the same time, the most difficult thing to obtain is apparently the proper compaction or interlocking of the broken stone. Almost always the rolling of the different courses is less than it should be for the best results, and the deficiencies in rolling are attempted to be made up for by using the screenings too soon and too profusely. Another problem is the securing of the utmost degree of uniformity in the macadam layer as to thickness, evenness and homogeneity—no irregular depths of stone, no irregular thickness of courses, no pockets of material which varies greatly in size, etc.

And with all these surfaces just mentioned, the speaker, at the risk of repeating, must again call attention to the problem of getting proper rolling or compaction.

With bituminous surfaces, the main problem is perhaps again the securing of uniformity; practically all defects may be traced to the lack of it. The use of mechanical appliances of course always helps in securing regularity and homogeneity and generally tends to ecomomy as well. Their desirability is beyond question.

With pavements of various kinds, perhaps a general statement might be made that one important problem is to get them as dense as possible, that is, with sheet pavements, such as asphalt, bitulithic, concrete, etc., the mineral portion must be so proportioned that the voids will be at a minimum and the cement must then fill the voids. The other necessities of homogeneity, or uniformity and compactness also apply. With block pavements, the joints must reach a minimum and then be properly filled. The blocks themselves need uniformity and they must be placed evenly and solidly.

The speaker trusts he may have given an idea of the problems to be encountered in construction, if not a solution for all of them. In solving them, one and all, no factors will count more than carefulness and experienced intelligence.

The mines branch of the government department of mines states that its demonstration of the commercial possibilities of peat as a fuel in Canada has been successfully completed, and that henceforth the activities of the branch would be applied in another direction, probably the economic production and testing of fuel, concerning which the department already has a man in the west. The peat industry in Canada will now become a matter of private enterprise. There are two big plants under construction, one at Alfred, Ont., and another at Farnham, Que., which are expected to supply Ottawa and Montreal and possibly other cities with cheap fuel. Their capacity is about 30,000 tons per year.

ROAD WORK IN MASSACHUSETTS.*

The Massachusetts Highway Commission during 1911 was successful in applying some of the extremely heavy bituminous materials with a pressure distributor, the pressure being provided by an ordinary air pump operated by steam from the traction engine. This has been applied in grouting as well as in surface treatment, and it seems probable that in the future it may be possible to use some of the more lasting bituminous materials containing large quantities of asphalt by this method and thus secure more permanency in both construction and surface treatment.

During the year the commission used over 1,500,000 gallons of various bituminous materials in the construction and surfacing its roads, including various tars, tarvias and asphaltic oils sold under different contract names. The chemist for the state Board of Health, H. W. Clark, reports that from a laboratory point of view the materials were rather better during 1911 than formerly; that there was, however, altogether too much variation between the different lots of what purported to be the same materials, sold under the same trade name, and that altogether too many of them frothed badly when heated. This lack of uniformity in the materials is largely responsible for the fact that while some of the roads on which these materials were used are now in very good conditions, others are not. For instance, one asphaltic oil had a viscosity of 390, while an oil sold under the same name and used at another point had a viscosity of 540, and still another shipment had a viscosity of 590. Another asphaltic oil varied in viscosity from 240 to 340.

Some of the sections that were treated with oil or tar two or three years ago have had to be treated. On the other hand, some roads which had considerable automobile travel were treated with a surface coating of asphaltic oil three years ago and are now in very fair condition, nothing having been done to them since except to patch the holes.

It now seems to the commission that a surface coat of asphaltic oil would not prove to be economical or satisfactory on a road which has a large amount of heavy teaming though it is satisfactory, or has been up to the present time, on roads which have a large amount of high-speed automobile travel, with but few heavily loaded teams.

The state highway in North Beverly was given a coat of heavy asphaltic oil, one-half gallon to the square yard, in the summer of 1910, but it did not wear satisfactorily. It began to wear out first on the north side of the road, where heavily loaded ice teams travelled. The other side of the [illegible] in fairly good condition for a longer period of time. By the end of the sea- [illegible]

---

*[illegible]

In general, other failures, not due to excessively heavy team travel, have been due to the qualities of the materials themselves, though in some cases they have been due to faulty application or to the fact that the road was not properly cleaned before the oil was applied.

It seems probable now that quite a few miles of the roads which had a surface treatment three years ago will only require extensive patching to carry them through another season, and that on others a little patching and a coat of one-quarter of a gallon of asphaltic oil to the square yard, instead of the half gallon which was first applied, will be sufficient to carry them through two seasons more.

◆

COST OF ROCK BALLAST.

The following figures of the actual cost of putting stone ballast under track, taken from the Railway Age Gazette, are of interest to track men as illustrating what can be done in this work with a good organization, where attention has been given to a careful planning of details. This work was done on a heavy traffic line where it was necessary to pass a large number of trains daily, the total raise amounting to about 10 in.

Number of yards	58,883
Digging out, unloading, putting under and dressing up	$ 7,763.40
Labor cost, per yard	$0.1318
Stone, 58,883 cu. yds.	$30,619.16
Digging out, unloading, putting under and dressing up	7,763.40
Engine service	2,385.00
Stone inspection	222.00
Total	$40,989.56
Cost per yard	$0.696
Putting in 9,310 ties, putting on 8,400 tieplates, gauging	$ 893.76
Cost per tie	$0.096

◆

REGULATION OF ST. JOHN RIVER.

A system of storage dams and other devices for regulating the flow of the St. John River is the principal recommendation by a board of consulting engineers to the International Commission, appointed some time ago to remedy conditions which now obtain. About a million dollars will be needed for the work, the expense of which will be borne jointly by Canada and the United States.

Beginning at a short distance above Grand Falls, N.B., where Canadian capitalists are now planning the erection of large pulp and paper mills, the river becomes international, and is the boundary between the United States and Canada. There have been recurrent difficulties in regard to the log drives, and at one time there were open hostilities, culminating in what is known as the Allejash War, when a dam was blown up by Canadian interests, and men employed by the American mill proprietors crossed the stream armed and threatened to shoot up those of the rival concern.

The commission appointed to enquire into the flow of the river, in order that uniformity at different seasons might be established, consisted of M. G. Teed, K.C., and John Keefe, of St. John, for Canada, and Hon. G. A. Murchie, of Calais, and Hon. P. C. Keegan, of Van Buren, Me., for the United States. S. Jefferson Chapleau, of Ottawa, and H. S. Ferguson, of New York, were joint engineers.

ELECTRIC FRANCHISES.*

By L. A. Cannon, K.C., Alderman of the City of Quebec.

The word "franchise" has various significations, both in a popular and in a legal sense, and confusion often arises from a failure to discriminate in what sense the word is used.

Thus, in a broad and popular sense, it embraces the right of trial by jury, the right of habeas corpus and political rights of subjects and citizens like the elective or electoral franchise.

In a strict legal sense franchises are special privileges which are conferred by government on individuals, and which do not belong to the citizens of the country generally of common right or by the operation of the "common law."

Franchises are of various kinds and may include amongst others, the right to construct and maintain electric lighting plant, the power to exercise the right of eminent domain, and as such, are of paramount interest to municipalities. It must be noted that the use of the streets of a municipality for delivering electricity to the consumer is a franchise—Parnell v. McLean, 96 Md. 589, 56 Atl. 83. But the right to produce and sell electricity as a commercial product is not a prerogative of government but is open to all, and hence is not a franchise.

Corporations or bodies politic, or the privileges conferred thereon, are the most usual franchises. The right to exist as a corporation is itself a franchise, and in addition to this the different powers and privileges which may be exercised by the corporation are, as a general rule, also franchises, but a corporation may possess powers which are not strictly franchises, such, for instance, as powers which belong to individuals by common right.

There is a marked distinction between a franchise which is essential to the creation and continued existence of a corporation—a right to exist as an artificial being, a right conferred by the sovereignty of the state—and those rights subsidiary in their nature by which the corporation obtains privileges of more or less value, to the enjoyment of which corporate existence is not a prerequisite. State v. Topeka Water Co., 61 Kan. 547, 558, 60 Pac. 337. In People v. State Bd. Tax Comr's, 174 N.X. 417, 435, 67 N.E. 69, it is said: "The general franchise of a corporation is its right to live and do business by the exercise of the corporate powers granted by the state. The general franchise of a street railroad company, for instance, is the special privilege conferred by the state upon a certain number of persons known as the corporators to become a street railroad corporation and to construct and operate a street railroad upon certain conditions. Such a franchise, however, gives the corporation no right to do anything in the public highways without special authority from the state, or some municipal officer or body acting under its authority. When a right of way over a public street is granted to such a corporation, with leave to construct and operate a street railway thereon, the privilege is known as a special franchise, or the right to do something in the public highway, which, except for the grant, would be a trespass."

It is essential to the character of a franchise that it should be a grant from a sovereign power.

The grant of a franchise, in so far as it is ambiguous, is to be strictly construed against the grantee and in favor of the public, and nothing will pass unless it is granted in clear and explicit terms.

Accordingly some of the authorities lay down the rule that a municipal corporation cannot confer a franchise, grants or privileges by municipalities being regarded by some of the courts as mere licenses or contracts. On the other hand it is held in some cases that the state may indirectly grant franchises, acting through the agency of a municipality.

When the application of electricity for light, heat, power and traction purposes was first introduced, the promoters of these different public utility corporations were looked upon to a certain extent as public spirited citizens who were investing their money and energy for the benefit of their fellow citizens, in ventures of a more or less secure character. Hence the very general tendency to grant to these persons or companies extraordinary privileges for the use of public streets, for the laying of tracks or the erection of poles, and the stringing of wires. These charters granted, as far as the Province of Quebec is concerned, from the early eighties to quite recent years, are now the cause of difficulties and problems with which municipal administrations have to contend.

In the Province of Quebec, special legislation must be obtained to incorporate a company for the construction and operation of either an electric or steam railway; companies, however, for the purpose of manufacturing, selling and distributing light and power can be incorporated either under Letters Patent granted under the Federal or Local Companies Act, or by a special act of Parliament or of the Legislature.

As a rule, however, since the organization of this Union of Canadian Municipalities, through the efforts of our representatives and officers, the Legislature of the province, and also, I believe, the Dominion Parliament, have protected the rights of the municipalities as to the control of their streets.

In our province the Legislature has even gone so far as limiting the powers of the municipal councils to grant franchise. The action of the elected representatives of the people must in some cases be ratified—to have full force and effect—by a special direct vote of the electors.

As a general rule, in the Province of Quebec, whenever a municipality grants to any person, firm or syndicate the privilege, right or franchise, for over ten years, of running a tramway or introducing an electric or gas lighting system in the municipality, the by-law or resolution relating thereto, must, before having force and effect, be approved by the majority in number of the municipal electors who vote on such by-law or resolution. Such vote must be taken within three months after the date in which the by-law was passed by the council, otherwise the latter would be null and void.

It must be said, however, that in a great many instances, under the terms of their charters, companies have been exempted from the operation of this clause, which, in some cases involving a large expenditure of money, might prove repellent to capitalists.

I may be permitted, before closing these remarks, to expose in a few words the situation of the city of Quebec with respect to this question of electric franchises.

For the last few years the ancient capital of Canada has been handicapped by the effects of inflated public service corporation capitalization. Since the consolidation, under the guidance of a well-known Montreal financier, of the different companies who had been competing together to furnish traction, light, gas and power to our population, the price of electric light and power had become prohibitive for industries intending to establish themselves in Quebec. You must bear in mind that the capital stock and bonds of the Quebec Railway, Light, Heat and Power Company amounts to nearly $20,000,000, which is out of all proportion to the size of the community which it serves. Quebec and Levis have a population of about 100,000 and in order to pay interest on this capitalization, the amount to be levied from the citizens is probably heavier than anywhere else in Canada. Although the company have done their best to swell their income, the operating expenses are too heavy, and the directors of the merger have been compelled to pass dividends on the common stock. It has been figured that each family in Quebec would have to pay about $200 yearly for traction, electric light and gas, in order to warrant the payment of such dividend.

---

*Paper read at the Convention of the Union of Canadian Municipalities at Windsor, Ontario, August 28th, 1912.

In 1910 the municipal elections were fought on this issue, and Mayor Drouin pledged himself to encourage competition at least for electric light and power.

A company, The Dorchester Electric, was organized with a capital of $1,000,000 to carry out this purpose, and, despite numerous difficulties which had to be overcome, was in a position to tender for lighting of the city streets for a period of ten years. This was a rather valuable contract and our call for tenders was framed in such a way that the interest of the consumer would be protected. The tenderer, besides quoting prices for the lighting of the public streets and squares, was called upon to bind himself to sell, during the period covered by their contract with the city, electricity to the public at a price not exceeding a certain maximum to be agreed upon. I will now quote some of the clauses which we have embodied in this contract and in the resolution granting them the right to enter the city of Quebec which had been previously given them. Our experience in the matter may be useful to younger municipalities who may have to deal with similar situations.

When the Dorchester Company applied for the authorization to introduce and sell electricity in the city of Quebec, we tried to ensure permanent competition by inserting the following conditions to prevent, as far as possible, the merger from taking control of the new company, either by buying a majority of the common stock or by obtaining their withdrawal from the field:—

(a) The said company binds itself not to cede or sell to any other company the powers conferred upon it by its letters patent, as regards the city of Quebec, without having previously obtained the consent of the city and the payment [illegible]

(b) If the company ceases to exercise its franchise in the present and future limits of the city during the ten years following the first of January, 1912, it will be subject to a [illegible]

(c) [illegible] ten cents per kilowatt hour for the price of its electricity in the present and future limits of the city, and that the maximum rate cannot be changed without the consent of the city.

(d) The company binds itself to pay to the said city of Quebec as a penalty $1,000 for each infraction of the above conditions, save in the case where a higher penalty has been [illegible]

[illegible]

[illegible]

year before the end of the contract then in force. Our call for tenders contained the following clauses:—

(a) The tenderer will be required to mention the price at which he binds himself to supply the current, lamps and lamp renewals, including the cost or rental of the electrometer for residential purposes in the city limits, at a maximum price not to exceed so much per k.w. hour net, and the rate charged to remain in force till the expiry of the contract with the city.

(b) The tenderer will be required to mention the price at which he binds himself to supply the current, lamps and lamp renewals, including the cost or rental of the electrometer for commercial purposes in the city limits, at a maximum price not to exceed so much per k.w. hour net and the rate charged to remain in force till the expiry of the contract with the city.

(c) The tenderer will be required to mention the price at which he binds himself to supply motive force in the city limits, at a maximum price not to exceed so much per horse power net, and the rate charged to remain in force till the expiry of the contract with the city.

The Quebec Railway, Light, Heat and Power Company did not care to bind themselves under these clauses, and the Dorchester Electric secured the contract under conditions entirely satisfactory to the public and at the same time a fair price that will enable the company to make a reasonable profit for their shareholders in view of their moderate capitalization.

The merger has been charging 15 cents per kilowatt hour for current consumed by private customers, while the Dorchester Electric Company will only charge seven and one quarter (7¼) cents for the same service for the next ten years. The city will pay nearly 50% less to the new company than they are paying under the present contract, and for lamps of the newest and most improved type. This should bring the conclusion that, although the universal high cost of living has manifested itself in Quebec as elsewhere, Quebec will not have cause for complaint in so far as the electric lighting and power business is concerned, when the new competing service begins operation next fall.

We have also decided to begin the installation of a system of ornamental posts on the principal streets designed to carry clusters of five lamps. These poles will be supplied, erected and wired by the city, and we will endeavor before the expiration of the contract to build a complete system covering the whole city.

I am strongly convinced that all municipalities should at least, even when the idea of a municipal plant for the production of electricity does not meet with favor, become owners of a complete system of poles and wires to distribute electricity all over their territory. This would make the city much more independent when renewals of contracts come, would secure cheaper rates for public lighting and would also be in the interest of the companies. The municipality would simply have, like all other private consumers of power, to buy the current at the switchboard direct from the producer and use it in its own plant or distributing system.

The company, not having to take into account when preparing its tender, the heavy cost of erecting, for a period of [illegible] years, a very expensive distributing plant that might prove useless if it failed to secure a renewal of their contract, would necessarily quote much lower figures not only for the lighting of streets and squares, but also for the current sold to consumers for ordinary commercial and residential purposes.

Thus we feel that, at any time, with a city-owned electric lighting plant, we will be in a splendid situation to municipalize the service if we deem it advisable.

There are many other aspects of this question of electric franchises that I would have liked to consider, but I must, under the rules of the association, close these remarks and thank you for your indulgence and kind attention, hoping that the foregoing may prove useful to some of our sister municipalities.

THE OVERHEAD PLANT OF A MODERN TELEPHONE SYSTEM.*

By Sergius P. Grace.

The public is ever wanting all poles removed and sees no reason why it should not be done, since the success of the underground wire distribution in the business districts of so many cities has been thoroughly demonstrated.

Now, all progressive telephone companies believe most thoroughly in underground distribution and are extending their underground conduits as rapidly as good economy for the benefit of both the public and the company will permit. Underground wires are cheaper to maintain than overhead wires, but the additional fixed charges brought about by the large sums required for underground work, make underground distribution prohibitive except in thickly settled business districts and along main feeder routes to the residence and other sections of the various cities.

In curve No. 1 are shown the varying costs between underground and overhead construction, from which it can be seen that not until we reach 800 to 900 pairs along a route can we truthfully say that underground construction in annual charges will be cheaper than overhead construction. The economical point will, however, vary in different parts of the country. Consequently the publicly despised pole lines must be brought into use on many streets and alleys of our various cities if we hope to give the public telephone service at a reasonable cost.

Those who are familiar with the congested and thickly settled cities of the East, such as Philadelphia, New York, Baltimore and Washington, where the entire city area covers a few square miles only, and, therefore, a large amount of underground conduits for distribution purposes is perfectly justified, perhaps do not realize the different conditions existing in some of the western cities, and particularly Pittsburg, where, because of the river valleys and the extremely rough topography of the surrounding hills, the city must necessarily spread over many square miles of area. Pittsburg, rather than being a condensed city, consists of a series of settlements, usually connected together along main business arteries through the valleys. For these reasons, we have had to confine our underground construction principally to the feeder routes through the valleys and rely upon side pole lines for distribution.

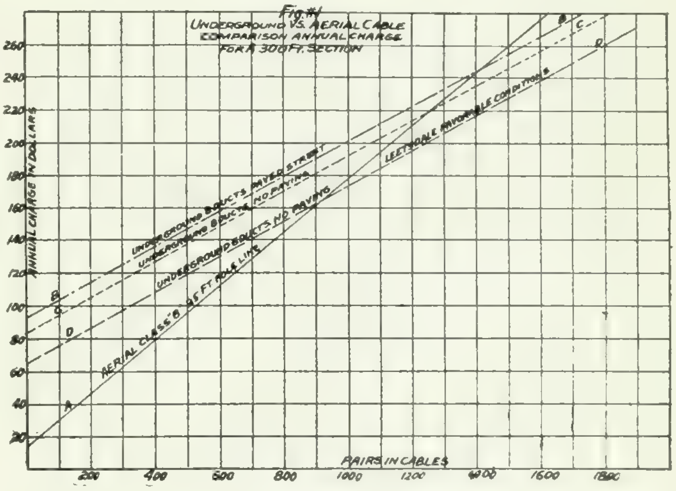
To have attempted a comprehensive scheme of underground distribution for each individual block throughout the city's territory would have been so enormously costly as to have financially embarrassed the company. Nevertheless, we have in Pittsburg about 110 miles of trench feet of conduit, in which is contained approximately 78 per cent of the total wire mileage of the city. You can see from this percentage, the part the main feeder routes play in the carrying of the main cables.

Realizing that in the present state of the art, we must make use of pole lines for distribution in cities, let us for a few moments trace the development of the pole line for telephone distribution service in exchange areas. The telegraph lines with high poles and bare iron wires on cross arms were developed before the invention of the telephone, and, with the introduction of telegraph engineers in the telephone business, it was only natural that the distribution lines should be patterned after the existing telegraph lines. Therefore, in the earlier days of distribution of telephone wires, wherever pole lines were used, it was the almost universal practice to erect very high poles, fifty to sixty feet high, and equip them with eight, ten or more cross arms, as the cases demanded.

These old-fashioned bare wire lines through city streets were very unsightly, and besides, gave an exceedingly large amount of trouble. In those days, the line trouble was very much greater than the switchboard or instrument trouble, and the bare wire distributing plant was usually considered to be the offender when any troubles occurred in the service.

When no more cross arms could be added to a pole line, recourse was had to short sections of cable, which were considered merely as auxiliaries to the bare wire lines.

In the territory of the Central District & Printing Telegraph Co., it was early seen that this type of distribution was practically impossible because of the winding streets, heavy grades, ravines and river valleys which are the accompaniments of a topographically rough country. Therefore, about 1896, to obviate these difficulties in the growing plant, the engineers of this company, principally Mr. Snyder and Mr. Donaldson, started a development and design of the aerial cable system of distribution which is standard to-day among all companies.



Curve No. 1.—Annual Charges of Underground and Aerial Construction.

The development of these designs changed the entire appearance of the overhead plant. Instead of high poles, with many cross arms filled with bare wires, we find to-day low poles, usually not over thirty-five feet in height, with aerial lead cables attached near their tops, no cross arms, but tapping boxes at alternate poles, with arrangements for connecting the distributing wires to the buildings. Practically no wire is carried back and forth along the lead, since by the multiple tapping scheme, a certain number of pairs are brought out to the terminals on alternate poles, so that, even for party line connections, the service wires may be run direct from the terminal to the subscribers' premises. The aerial plant of the C. D. & P. T. Co. now represents 36 per cent. of the total plant investment, over one-third of which is cable.

Besides greatly improving the appearance of the overhead plant, and thus lessening the chances of public criticism, this style of construction has greatly reduced the troubles from the wire plant. In studies which we have made of trouble in modern plants, we find about the following percentages:—

---

* Paper read before the Philadelphia Telephone Society and published in the Telephone News.

Switchboard trouble ....58 per cent.
Inside wiring and substation trouble....28 per cent.

This leaves only 14 per cent. as chargeable against the outside plant between the terminals on the main frame and the terminals of the protectors at the subscribers' houses.

In other words, the outside wire plant, which is exposed to all the elements, is responsible to-day for only 14 per cent. of the total service interruptions. This is a direct reversal of conditions in the older days, and perhaps the principal comment would be that there is no necessity for so much switchboard and substation trouble. The maintenance of substation apparatus costs as much as the maintenance of the entire outside plant.

There are a variety of opinions as to the economy of party line service from a plant standpoint, particularly in exchanges of 500 to 2,000 stations, in which places the outside plant is nearly always an aerial cable system. It has been said that any existing party line plant could be changed to single line with a comparatively small investment in cable pairs. This is true, but our exchanges do not grow that way in lumps, but gradually. Additional new lines would cost still more, or, because of the increased number of lines and reduced annual charges per line, party line service could be given more cheaply than ever.

In a gradually growing plant, if supervision is given to effecting party line combinations of an average of 1.8 for two-party and three for four-party, our studies indicate that the annual cost of a single line station is 1.5 times more than for a two-party and 2.3 times more for a four-party station. Curve No. 2 shows this relation for exchanges in which the annual cost constant varies from $20 to $32 per line. The annual cost constant is for all the outside plant except drops and substation apparatus. There is clearly plant economy in party line service.

The principal units entering into overhead construction are poles, cross arms, cable, insulators, hardware and wire. In this country practically all telephone poles are of wood. The kinds of wood most generally used are cedar, chestnut and creosoted pine. Each has its locality where it is most economical and most generally used. There is, however, an increasing tendency to make use of other kinds of timber, particularly after being given a creosoted treatment.

Steel poles have been used very little in telephone work, although extensively used by the railway companies for trolley poles. In large sizes they are many times more costly than wooden poles, and, besides, require constant upkeep in the way of painting. I feel sure that in the next [illegible] properly designed [illegible] present the least [illegible]

[illegible] to reduce the number of poles in the various municipalities. It must be admitted that this is a reasonable request on the part of the [illegible]

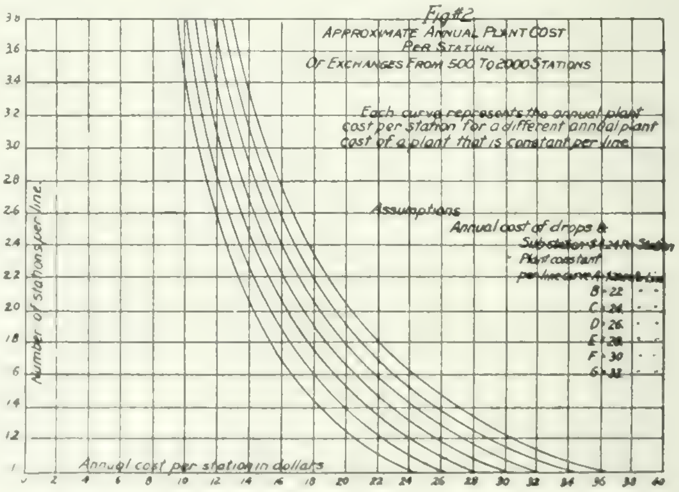
[illegible]

[illegible] joint pole line construction is safer to life and property than separate lines.

In many parts of the country, joint agreements have been perfected with the light companies, the standard specifications of the American Telephone & Telegraph Co. being substantially followed.

As a word of warning, I wish to say that unless we voluntarily go into these joint pole propositions, we will in a short time be facing regulation of our construction by the engineers of the various public service commissions, which is very likely to introduce special methods for each State. At the present time the Bell system is national in its scope and we are able to effect great economies in engineering and construction by uniform design. To have this great advantage in uniform methods set aside would be a decided step backward.

Of course, you have all heard of Pittsburg smoke and are willing to believe that Pittsburg is just as black as it is painted. It would be futile for me to argue with you on this subject, and tell you of the glorious sunrises I see from my home on Squirrel Hill, when Dooley is authority for the statement that in Pittsburg every other building is either a blast furnace or a Carnegie library. We do have smoke in our river valleys and blast furnace fumes in the air, which, aside from their esthetic effect, are decidedly destructive to our pole line hardware, such as braces, bolts, terminals, hangers and strand. For years we have had rigid specifications for this class of material and found it necessary to use only the best of galvanizing for protecting the steel.



Curve No. 2.—Annual Plant Costs per Station, Different Size Exchanges.

Unless one is thoroughly familiar with the principles underlying the protective action of galvanizing or zincing, when applied to steel, he will be deceived at the apparent long life of even defectively galvanized or cracked materials. Zinc is electro-positive to iron, and when a scratch or worn part goes through to the iron, there will be an electro-chemical effect set up which slowly consumes the zinc, but protects the iron from rusting; consequently for several months or years, the exposed iron or steel will show very little rust or corrosion until finally the surrounding zinc has been so thoroughly eaten away that it can no longer protect the iron electro-chemically, and then rusting will start at a rapid rate. This is why galvanized material that has stood up well, for perhaps four, five, six or seven years, may [illegible] of two additional years be completely rusted away.

Having heard so much about it, I know that you will be interested in an analysis of Pittsburg air made by Doctor

Phillips, of the University of Pittsburg. Doctor Phillips collected samples or rain-water at the beginning, the middle and the end of various showers. This water, having passed through the atmosphere, would naturally collect any foreign gases soluble in water and would also carry along with it any soot particles with which it came in contact.

The most remarkable thing about these tests, and the least expected, was the fact that rain-water collected, after passing through the Pittsburg atmosphere, contained no trace of sulphuric acid. There was, however, found a small amount of ammonium sulphate, showing that the nitrogen in the air had combined with the sulphur dioxide and neutralized it. The amount of carbon dioxide was only two-thirds greater than in normal air, such as is found in Northern Canada. Whatever nitric acid might have been generated had been converted into ammonia. The atmosphere seemed to be entirely free from acid; in fact, was quite alkaline. It was found, however, that there was an active corrosive agent in the Pittsburg atmosphere. This is the soot, which, being very porous, absorbs a considerable amount of sulphur, and when wet contains about two per cent. of free sulphuric acid. Apparently, then, the corrosive action in the Pittsburg atmosphere is largely due to the collection of soot upon the surface of the coated metal and the liberation of sulphuric acid during the rain-storms.

The recent introduction of loading coils in aerial toll lines has made it particularly necessary that the insulation of these lines be kept very high. This has led to the very careful maintenance of the right of way of the pole lines and the trimming of all tree limbs that might come in contact with the wires. Also on some of the longest lines, porcelain insulators, which have a higher insulation resistance during rainstorms than glass, have been used to good advantage.

In the Pittsburg district, where the toll lines traverse the river valleys in the neighborhood of the steel mills, we find it difficult to maintain a high insulation due to the accumulation of soot, and on a number of routes we have had the utmost difficulty in keeping the lines working because of the accumulation of iron ore dust on the insulators and cross arms. This dust is of a metallic nature and floats through the air because of slips which frequently take place inside the blast furnaces during the feeding.

For toll line purposes, where bare wire is necessary, the universal practice is to use hard-drawn copper, with the possible exception of certain rural districts, where it is certain that no very long distance calls will be made. Under ordinary atmospheric conditions, copper is practically indestructible. There is an authentic case of a sheet copper statute in one of the interior towns of France, that in 200 years has lost in thickness only 1/1000 of an inch. Copper wire in the Pittsburg district does not seem to deteriorate except in the vicinity of coke ovens, whose fumes contain the hundreds of coal tar derivatives.

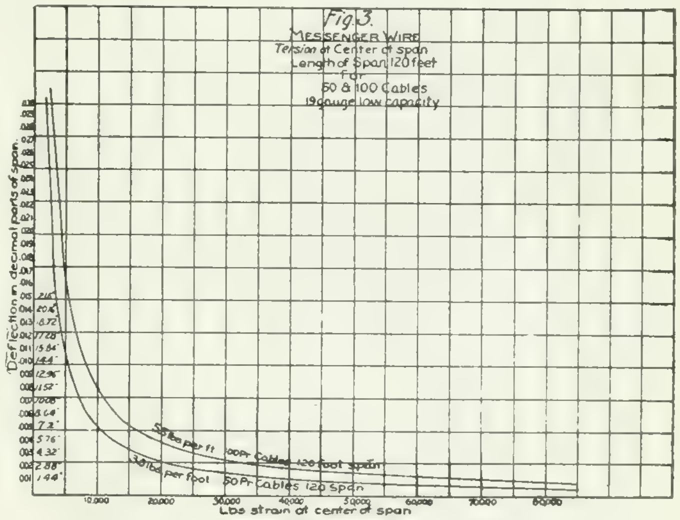
In some locations we have had to renew copper wires every three or four years. Iron wire is of practically no value in the Pittsburg territory except in the remote interior country sections. In exchange distribution, because of the introduction of the aerial cable system of distribution, there is very little need of bare wire for distribution purposes. There are a few places, particularly suburban districts, where bare wire on cross arms is more economical during the initial period than cable or insulated wire.

Generally speaking, the distribution in exchanges to-day is made almost entirely with cable and twisted pair distributing wires. There are many advantages in the use of twisted distributing wire, among which may be mentioned the freedom from trouble with electric light and power crosses. The twisted wire does not need to be strung on expensive cross arms, but can be attached, by means of small iron brackets and porcelain insulators, direct to the pole itself. The labor of stringing is very much less than bare wire, and the same thing may be said of removing the wire after it is out of service.

It makes a very convenient and economical type of unit construction, which can be used for establishing service prior to the time it is thoroughly demonstrated a cable will be warranted along the route. When the cable is placed the drop wires can be connected directly into the terminals, and that portion of the twist strung along the pole line can be taken down and used for other drop wires. The transfer expense is therefore small.

Until March, 1910, it was the general practice to use, for distributing purposes, No. 14 B. & S. gauge copper, rubber covered and braided distributing wire. This made a first-class installation, but the wire was needlessly large and contained more copper, rubber and braid than necessary. Since the drop wire is usually connected to a 22-gauge cable pair, it can readily be seen that No. 14 copper wire was used for strength alone and not for its conductivity.

For the past two years the practice has been to use No. 17 B. & S. gauge copper steel, rubber covered and braided distributing wire. This wire has nearly the same tensile strength as the old No. 14 wire, but because of its lesser weight per foot, has a much greater factor of safety under all conditions of sag and ice-loading. Its cost is about $25 per mile less than the old No. 14 wire.



Curve No. 3.—Tension of Messenger Wires in Centre of Span.

While on the subject of rubber covered wire, I would like to state that a good rubber wire is an economical investment, whereas a poor rubber wire is the poorest kind of an investment.

During the early period of the introduction of the aerial cable system in our territory, we were particularly careful as to the quality of the rubber wire we purchased. As a result all of the earlier wire has stood up in practice exceedingly well and undoubtedly has had a life of at least ten years. As an argument in proof of this statement, I wish to give you tests we made on samples of rubber wire from Wheeling, W. Va., which we were positive had been in service for a period of ten years.

Except for a few spots where the wire was mechanically injured it was in fairly good condition and capable of giving several years' additional service. The rubber still had considerable life and, when the wire was subjected to a tank insulation test, showed an insulation resistance of 232 megohms per mile after an immersion of 18 hours.

(To be continued.)

HYGIENE OF THE STEEL TRADE.

Before the Industrial Hygiene Section at the Royal Sanitary Institute Congress at York, on July 31st, Professor J. M. Beattie (University of Sheffield) read a paper on the above subject, in the course of which he said that a great deal of attention had been centred on the dust problem, and much of the legislation relating to the industries with which they were dealing was concerned with the protection of the workers from dust inhalation. To his mind the much more serious problem, the prevention of infection with tuberculosis, had not received justice at the hands of factory inspectors and factory legislators. During a five years' experience in Sheffield it had been abundantly demonstrated to him that the cutlers and grinders die from tuberculosis, and not from non-tuberculosis fibrosis of the lung.

Professor Beattie exhibited a number of lantern slides, showing how dust blocks the lung tissue, and expressed the view that whilst the tubercle bacillus obtained an easy lodgment in these parts, yet its spread was hindered by the fibrous tissue. The means for the distribution of the tubercle bacillus were obvious to anyone walking through the grinding hulls. The men spat on the wheels in the trough in which water for the wet grinding was contained, and on their hands as they got renewed grips on the blade they were grinding. During the grinding process the blade was dipped constantly into a bucket of water, which the man had at his side, and the sputum which had got on to his hands and on the blade was washed into the bucket, which soon became a perfect storehouse of tuberculosis. The spray, loaded with bacilli, was scattered over the hull, the man himself and his fellow workers. This applied particularly to the wet grinder, who was not supposed to inhale much dust. The grinders themselves said they inhaled no dust, but very little inquiry soon showed the fallacy of this assertion. The wet grinder acknowledged that he got a considerable amount of irritation about his throat, but attributed this to fumes resulting from the heat generated during the grinding process. There was no doubt that the finer particles of the stone were dried by the heat generated during the process of grinding, and that this fine dust was inhaled, and he (the speaker) believed the irritation to be due to this. He did not wish to take too much of the view that fibrosis hindered the spread of tuberculosis, but he thought there was room for further investigation as to whether the inhalation of a mixture of dust and tuberculosis was not less likely to produce rapidly spreading tuberculosis than an inhalation of tuberculosis alone.

It is unnecessary to deal specially with the dry grinder and the cutler. It was unquestioned that the tuberculosis from one man might infect a whole workshop if that man's sputum was allowed to get mixed up in any way with the dust. In fact, the distribution was more easy with the dry grinder than with the wet. He would urge much more care in eliminating the tuberculosis from the workshop. So long as they allowed people infected with tuberculosis to work among their fellows, and at the same time did not enforce the strictest regulations to stop spitting, then all the elabor- [illegible]

THE SPOUTING OF CONCRETE.

[illegible]

Having given the proper proportions to the ingredients it is absolutely necessary that enough water be added to the conglomerate to produce a specific gravity such that the rock is held in suspension; the mixture will then flow like a thick gravy with no sign of excess water; in other words, it should have a saturated amount of water and no more. This particular mixture is surprisingly slippery and flows readily around all steel. It has an oily nature which is due to the cement.

In placing concrete by the gravity system there are three operations: The mixing of the ingredients, stone, sand and cement, in a suitable batch mixer; hoisting of the mixed concrete by skip to an elevated hopper; and the transferring of the concrete through pipes leading from this hopper to the point where it is desired to be poured.

The following general instructions for operating a spouting system may be of value:

1. Run about 10 feet of water in skip.

2. Charge mixers, using mostly sand with the cement and plenty of water.

3. Run up skip with water and drop at once, following up as quickly as possible with a charge of concrete.

4. Run the mixture so that it may have the consistency of a thick gravy, so that when it levels off the rock is seen held in suspension. If when dumped in the skip it stands up, it is too thick; if it levels off and shows one inch of water, it is too thin.

5. There should be a man in the tower to operate the concrete gate on the hopper to regulate the flow of concrete through the pipes. The stream should fill about one-third of the conveyor pipe and the charge should be so timed that the stream will be as continuous as possible.

6. The continuous and successful running depends on the uniform mixture. Be careful not to get it too thin. After a shut down of over ten minutes, flush the pipe by sending up ten feet of water in the skip.

7. At the end of the day's run clean out the mixers with two charges of water. Send these through the pipes.

8. All pipe joints should be oiled with thick grease so as to prevent sticking.

It is in general not advisable for any contractor to use the gravity system for the first time on a job of less than 2,500 cubic yards. However, it has been successfully used on jobs as low as 250 cubic yards. In these cases the apparatus was on hand and the men were acquainted with its operation.

◆

LABOR UNREST STILL ON THE INCREASE.

Industrial conditions were seriously disturbed by labor disputes during July, the number in existence in that month being considerably greater than the number existing during June. The number actually commencing, however, during July compares favorably with that of the previous month. In all, forty-six disputes were reported to the Department, an increase of nine as compared with June, and an increase of [illegible] as compared with July, 1911. About [illegible] employees were affected by these disputes as compared with [illegible] during June and 19,000 during July, 1911. A termination of the garment workers' strike in Montreal occurred during July, which caused a resumption of operations by more than four thousand employees after nearly two months of idleness. Few of the disputes commencing during July were individually of serious consequence as factors in disturbing industrial conditions.

THE DOUBLE-DECK STREET CAR.

An aid towards the solution of the problem of handling transportation in the larger cities of the States has materialized in New York and Pittsburg in the use of double-deck cars. These cars have been introduced almost simultaneously, and are now in operation. Their use in these cities will be viewed with considerable interest.

Their use is attended by many favorable conditions. The double-deck car takes only the track space of one car, but gives the seating capacity of two. At the times of congested traffic this is a decided advantage, in that it will allow the doubling of the number of cars on any one street. In England the double-deck car, or omnibus, has been used for a considerable period of time, but these cars are the first appearance on this continent. The operating expenses will be lessened by their use on account of only one crew being requird to operate the car.

If these cars are a success, as in all probability they will, no doubt their use will be taken up by the larger Canadian cities where congested conditions exist. Their use, for instance, in Toronto in the down-town areas would do much to relieve conditions during the rush hours.

◆

THE CONTROL OF OUR RIVERS.

The increasing damage resulting from floods on the streams of the more settled sections of the country will necessitate, in the near future, some adequate action for the control of the water during times of freshet. A deputation waited on the Ontario Provincial Government last week to secure action with regard to the control of the Grand River. The deputation from the Grand River valley urged the Premier to initiate an investigation into the effect of spring floods on that river with a view to taking some preventative action.

The Grand River question has been brought to the attention of the Government before, but as yet no move has been made towards conducting an investigation. In this argument presented to the Government it was shown that not only could the damage by floods to a great extent be obviated by control, but that the increase in the minimum summer flow as the result of storage would mean a considerable gain in horse-power on the existing water-power developments of the river, with the addition of new water-power possibilities. Water supply, sanitation and general benefit would be the result of securing a uniform flow on the river. The Grand River drainage area and the hydrographic conditions surrounding it appear to point to storage as the economic and feasible solution for the control of its water. Reforestation is of doubtful practicability in connection with this river.

The Premier seemed rather cool towards the delegation. His answer that the people in other sections of the province were troubled in the same way is quite true, and the subject opened up is a large one. Nevertheless, it is time that some action was taken with regard to the problem. Before any constructive work can be done it will be necessary to investigate the conditions existing, and this will take some time. It is desirable, therefore, that some immediate action be taken towards securing the necessary data, and it is hoped that the provincial government can see their way clear to provide the funds for an engineering invesgation.

THE PANAMA CANAL BILL.

One more milestone was reached when the United States Senate two weeks ago passed the Panama Canal administration bill. This bill contains a provision exempting United States merchant ships from the payment of canal tolls, while foreign ships remain subject to them. That exemption is a direct violation of the Hay-Pauncefote Treaty, which was ratified in 1911. The bill was passed in the face of direct protest registered by the British Government and against public feeling in the United States as expressed by the responsible newspapers. We feel satisfied that the prevailing sentiment throughout the United States is against this action on the part of the Senate. It will have the effect of making nations dubious about trusting to the honor of the country in future negotiations. It is no light thing in international politics to repudiate pledges made by one responsible country to another.

Aside from the effects of this breach of faith on the part of the Senate, it is an open question whether it is good business to subsidize water-borne commerce. It is a well-known fact that water rates are adjusted to fall slightly below the rates of the railroad. The coast shipping of the United States, which is expected to benefit by the exemption of tolls, is well able to pay the same tolls as the ships of foreign register, and there is no reason why they should not pay these tolls to help cover the investment in the Panama Canal.

The western harbors of Canada have a great future ahead of them in the opening of this new avenue of commerce. Even if Vancouver is penalized to the extent of $1.25 toll over Seattle, there remains a great future for the port as a result of the opening of the Canal. It is pleasing to note that the Canadian harbors on the Pacific are being prepared for the greatly increased development to be expected in the near future. In this issue of *The Canadian Engineer* some details are given of the improvement to be made at once on the Victoria harbor. The Government is alive to the necessity for prompt action with regard to the development of the western ports.

◆

DEVELOPMENT OF MONTREAL PORT

The Harbor Commissioners of Montreal have in view a comprehensive plan for the development of that port, a plan, in fact, which involves the expenditure of many millions and the practical transformation of dockage facilities. When the commissioners took office some years ago, they paid immediate attention to future requirements as well as to those of that time. As a result they had the engineers prepare plans which they expected would take a dozen years to materialize. These plans are gradually developing as the work proceeds.

Among the objects of the commissioners is that of reducing the flow of water which now meets the ships coming up the current in front of the city. For that purpose they have considered plans by which much of the water will be diverted between St. Helen's Island and the south shore. The reduction of the current in the upper part of the harbor and the possible changing of the inlet to the Lachine Canal are under discussion.

The commissioners may likely construct a bridge to connect the city and the south shore. The city end of the bridge would apparently rest upon the end of [illegible] pier to be built outward from the city. The other end would rest upon the west end of St. Helen's Island. From there to the south shore, the work will be a simple matter. By following this route, the difficulty of carrying the bridge above the masts of incoming steamers disappears, as the vessels do not proceed so far upwards from the sea. Residents both of Montreal and of the south shore welcome the announcement. No doubt street car facilities will be provided.

◆

EDITORIAL COMMENT.

The Canadian National Exhibition is again in full swing, bigger and better than ever this year.

* * * *

Hamilton is up against the sewage disposal question. The city has grown so fast that the present methods of handling city sewage are considerably overtaxed. The city engineer has impressed on the council the necessity for prompt action. It is to be hoped that such action will be taken without the necessity of intervention on the part of the Provincial Public Health Department.

* * * *

The City Council of Kingston appear to know more concerning technical matters than their expert advisers. They have decided to enlarge the present steam plant in the face of the advice of their consulting engineers, who are strongly opposed to such a step. The education of our public men must be developed in the near future, if the public are to secure the economical spending of money for public utilities.

* * * *

The Medical Health Officer of Toronto certainly understands the art of procuring advances in salary to hold his employees. The civic position of epidemiologist has been created to keep one of the assistants in the Medical Health Department of the city. If the city engineers of some of our cities were as earnest in the securing of reasonable remuneration for their assistants, the engineering profession in Canada, as a whole, would be on a higher plane.

* * * *

During the progress of the inquest at the time of the Neilson building collapse at Toronto, we had occasion to refer at different times to the methods of carrying on the City Architect's Department. Since that time serious criticism has been levelled at this department from many sources. It is time that some adequate endeavor was made by the city officials to put this department in shape. The complaints of the structural engineers of the city justify energetic actions at once.

THE NEW TRANS-AUSTRALIAN RAILWAY.

The placing of contracts for the immense amount of material required for the construction of the Kalgoorlie, W.A.-Port Augusta, S.A., railway has been delayed owing to a difficulty which had arisen between the Commonwealth and South Australia. The point in dispute was that of the land desired by the Federal Government, and this issue has now been settled by compromise. Tenders for 135,000 tons of steel [illegible], [illegible] tons of iron dog spikes, 2,200,000 sleepers (reinforced concrete, timber or steel), and [illegible] pairs of wheels and axles, are now under consideration. The total amount of expenditure on materials is estimated approximately at [illegible]. It has been decided to call [illegible] tenders for the supply of points and crossings, and [illegible] of the railway. While the State Government of Western Australia stipulates that the railway will require a large number of local (jarrah) sleepers, it has not yet been definitely decided whether the sleepers will be of wood, steel or reinforced concrete.

NEW BREAKWATER FOR VICTORIA, B.C.

Plans and specifications for the construction of the breakwater from Ogden Point, Victoria, B.C., have been prepared by the Department of Public Works. Tenders will be received from contractors up to September 5th. The work is to be completed in three years. The specifications provide that the construction is to be commenced immediately that the successful tenderers have been notified, and must be proceeded with in such a manner as will satisfy the Department of Public Works that the whole work can be completed within thirty-six months from the date of notification of acceptance of the tender.

The breakwater will extend from Ogden Point for a total length of 2,580 feet. It will run 330 feet south and thence westerly 1,500 feet, and curve thence northwesterly 750 feet (Fig. 1). The plans and specifications provide for a rubble mound surmounted by a wall of mass concrete for the whole length, with heavy granite blocks on the seaward side.

This is the first part of the harbor works to be provided to properly equip the port of Victoria to handle the great shipping trade that will follow the opening of the Panama Canal. It will shelter five modern concrete piers to provide berthing space for twenty or more of the larger steamers. These piers will be equipped with warehouses, cranes and all modern facilities for cheaply and expeditiously handling cargo. Spacious basins will be provided between the piers, and when the whole scheme is complete it will offer a harbor second to none on the North Pacific coast.

The plans under which the breakwater will be constructed are shown in the figures, and indicate the character of the work. The rubble mound will be 64 feet in width at the line of extreme low water at the ordinary stage of the tide. From this elevation the mound will slope on the exposed side at an inclination of 1½ feet horizontal to 1 foot vertical, and the slope on the harbor side will be 1 foot in 1 foot. These slopes will be continued when the concrete, topping the mound, is completed. A core of quarry stones will be allowed to a height of 35 feet, with a width of 62 feet at the top, and with a slope of 1 in 1 to the bottom. The remainder of the stone in the mound, except the large blocks shown in Figs, 2 and 4, on the exposed side, will be built with stone blocks of approved quality at least half weighing not less than a ton each.

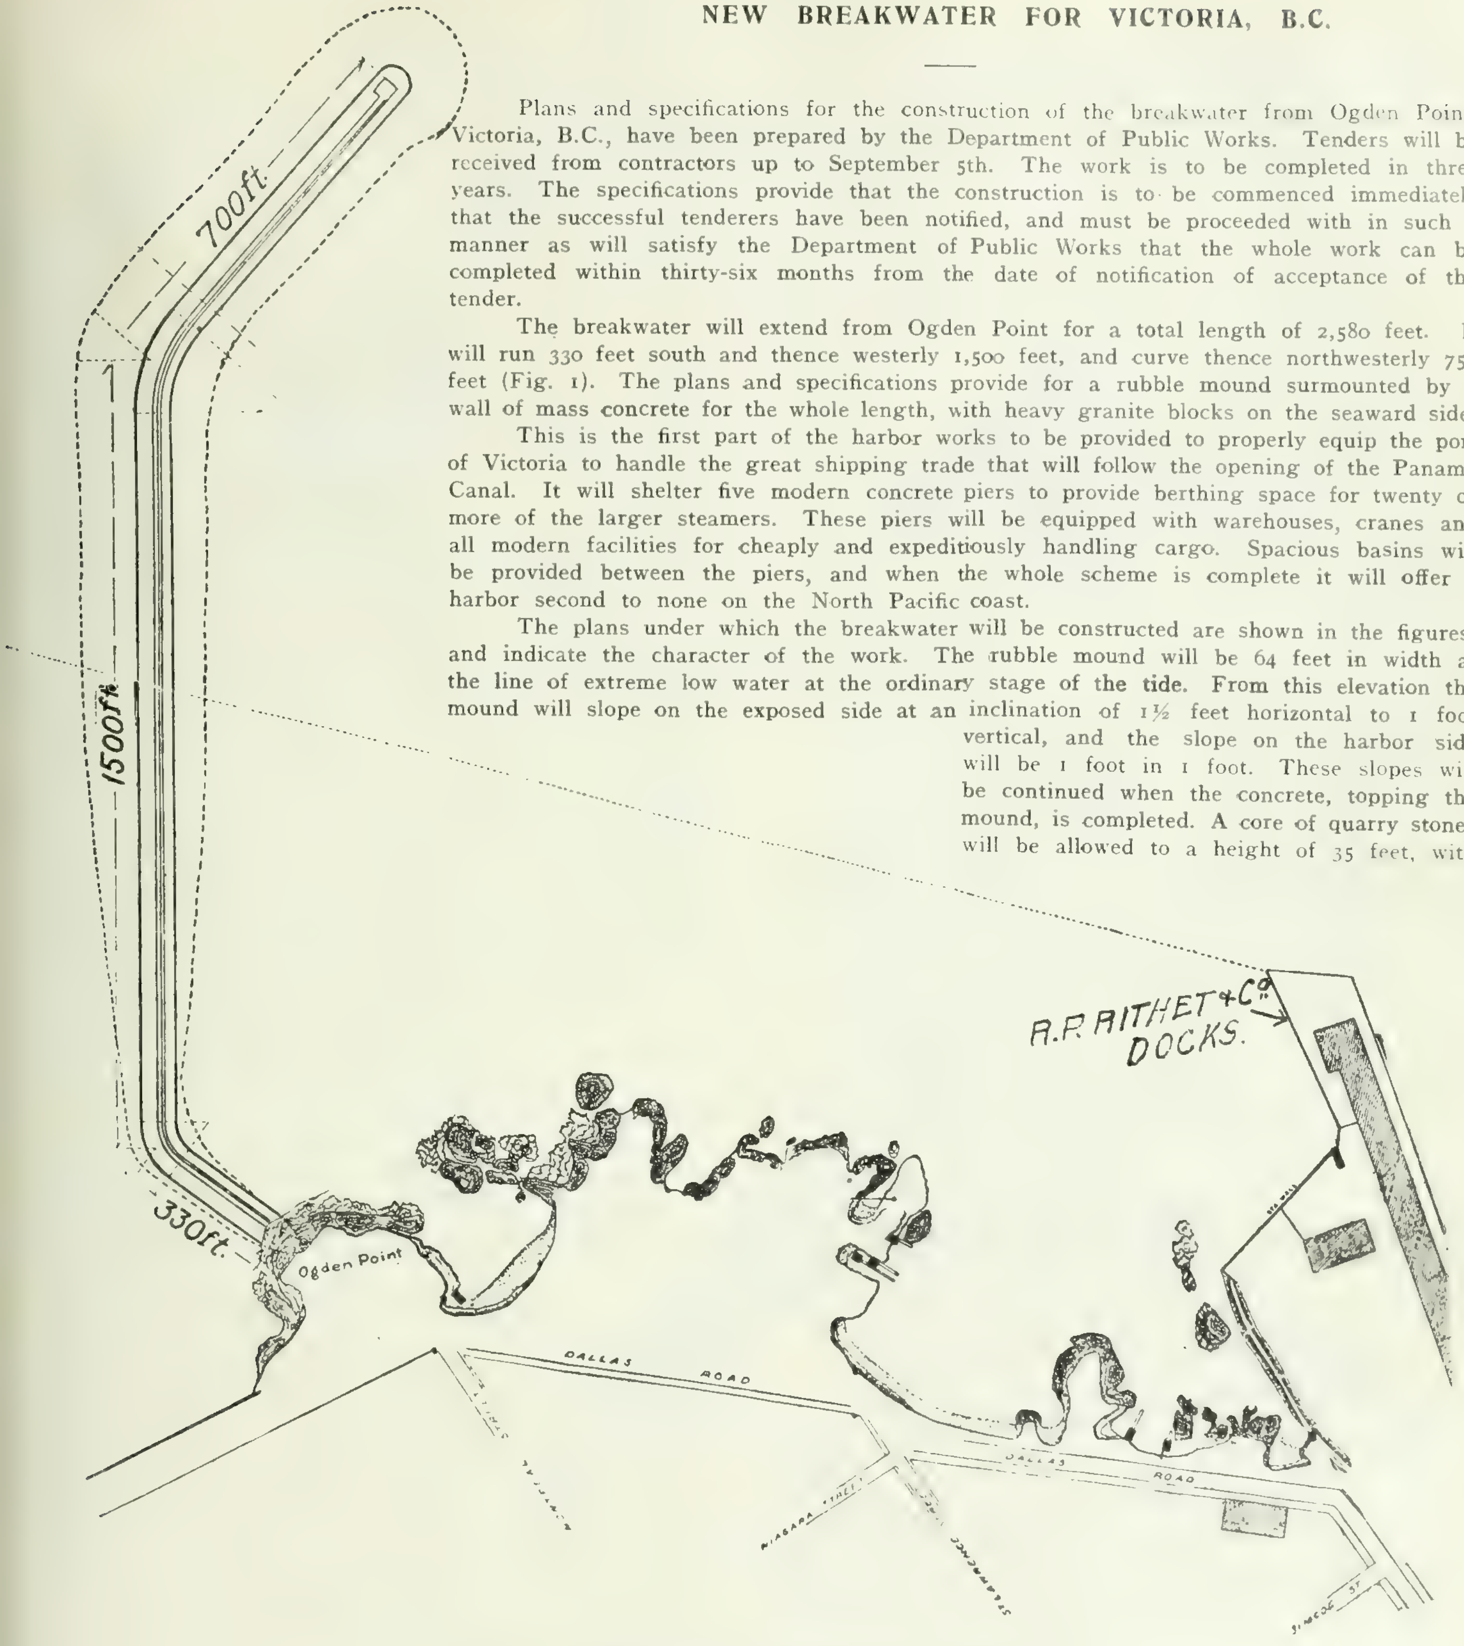

Fig. 1.—Location of New Breakwater at Victoria, B.C.

The large blocks on the exposed side, from a depth of 20 feet below water level, and averaging 18 feet in thickness, will be built of granite blocks weighing not less than six tons each, and 50 per cent. of the facing stones of this part shall weigh not less than eight tons each. These stones are to be carefully quarried, cut in rectangular blocks, laid so as to bond well, the joints not to be wider than eight inches in any part. All of the stone used will be durable rock of approved quality, to weigh not less than 170 pounds to the cubic foot, the least dimension of any stones to be not less than a quarter of the largest dimension. The large blocks on the exposed face will be all of granite.

The concrete wall will be built the full length of the breakwater. The bottom of this wall will be built on the top of the rubble mound, 20 feet wide at the bottom, and 26 feet in height. The bottom of the concrete wall will be about the height of extreme low water, and will batter on the harbor side to a width of 15 feet at a height of 21 feet, and the remaining five feet will be 10 feet in width. The section shown in Fig. 3 indicates the elevation of this wall and the manner in which it will be battered and stepped. Provision will be made for the construction of a lighthouse at the end of the breakwater.

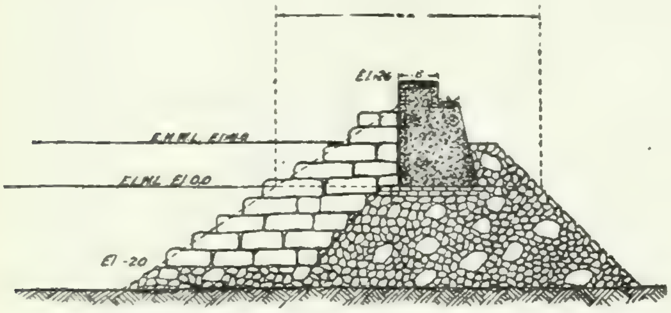

Fig. 2.—Section Through Breakwater at Shore End.

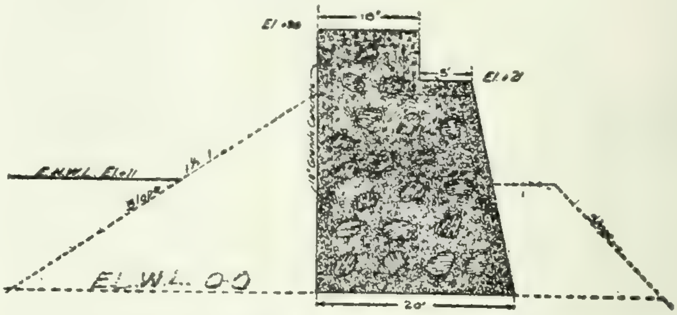

Fig. 3.—Section Through Concrete Wall of Breakwater.

The specifications provide for the fair and proper treatment of workmen who will be given employment. The contractor will be obliged to conform to regulations respecting the accommodation, medical treatment and sanitary protection of all workmen on the work.

All workmen shall be residents of Canada, unless the Minister is of opinion that Canadian labor is not available, or that emergencies or other special circumstances exist [illegible] this.

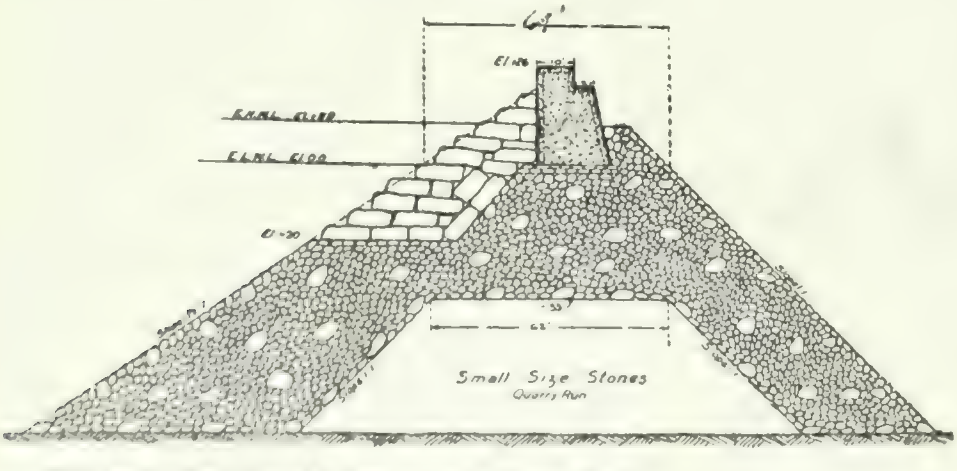

Fig. 4. Section Through Breakwater at Outer End.

No workman shall at any time be paid less than the [illegible]

[illegible]	$4 75
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
Hand drillers	3 00
Powder men	3 50
Quarrymen	3 00
Laborers	3 00
Diver, with outfit	15 00
Diver, without outfit	10 00
Driver, with one horse and cart	5 00
Driver, with two horses and wagon	7 00

The following minimum monthly rates of wages are to be paid, in addition to boarding men, as follows:—

Tug captains	$100 00
Tug engineers	90 00
Tug firemen	60 00
Deckhands	45 00
Scowmen	45 00
Timekeepers	65 00

The bids to be submitted will be compared on the basis of estimated quantities of work to be done, the quantities to be considered as approximate, and the Department reserves the right of increasing or diminishing any or all of the items. Core stone, quarry run, 306,381 tons; rubble stone, 50 per cent. to the ton, 719,838 tons; granite blocks of six tons and over, 113,322 tons; concrete for facing, 9,031 cubic yards; concrete, 39,832 cubic yards.

◆

INDUSTRIAL ACCIDENTS.

During the month of May there were 108 fatal and 272 non-fatal accidents recorded by the Department of Labor. This is an increase of 46 fatal and 38 non-fatal accidents compared with the record for June, and an increase of 10 fatal and 73 non-fatal accidents compared with July, 1911. Accidents recorded in which more than two workmen were killed were: One as the result of a falling derrick at Kenogami, Que., on July 1st, by which seven men were killed; one by which four railway construction hands were killed by a premature explosion of dynamite on July [illegible], near [illegible], Ont.; one at Kenogami on July [illegible] by which four men were killed. Two accidents were occasioned as the result of a falling pile driver coming in contact with live wires at Meaford, Ont., on July [illegible].

The municipal council of Toronto has recently awarded a contract for the manufacture and installation of a number of target light reflectors for the night illumination of various clocks about the city that are under the care of the council. These appliances are to cost $[illegible] each.

BRIDGE RENEWALS.

A number of wooden Howe trusses on the Louisville division of the Pennsylvania Lines West have been replaced with steel girder or truss spans during the last few years, and in the work of replacing these bridges considerable care has been taken to eliminate the necessity for heavy false work, and also to economize in the use of work trains by substituting a light maintenance derrick car whenever possible. Two examples typical of the methods used in this work were described recently in the Railway Age Gazette and are illustrated herewith.

In the first case, shown in Fig. 1, a 146-ft. 5-in. Howe truss and three spans of trestle approach were replaced by three deck girder spans, one 40 ft. long and two 70 ft. long. A spur track was built immediately south of the old bridge, and from this track all material used in the work was handled by the derrick car under its own power. The masonry was first completed and the iron bent for the central girder support was erected on the new pier. The 40-ft. girder replacing the old trestle approach was placed in the usual manner. Two additional floor beams were inserted in each panel of the old truss and the truss was raised about 20 in., the elevation of the rail being kept constant by removing the ties and stringers and spiking the rails directly to the floor beams. The two main-girder spans were assembled and floored on the spur track and were put in place on two successive Sundays when a period of 5½ hours between trains was available. A yard engine was brought 10 miles for the purpose of moving the girders. The rails, floor beams and lateral bracing of the old bridge being removed, the girder spans were lowered into place with jacks, the track was replaced and the load carried on the girders. False work was then driven under the Howe truss and it was dismantled and loaded. As shown in the illustration, this false work was very light, as it carried only the dead weight of the old truss and was only in place for a short time.

In the second case, shown in Fig. 2, a 160-ft. through truss was replaced by two half through girder spans, each 80 ft. long. The delivery of the iron was contracted for in December, making it certain that work would be under way during the winter season when trouble can be expected from running ice and drift. All the masonry work was completed during the early fall except the portion of the abutments under the old through truss. Three heavy cluster pile bents were driven adjoining the abutments and the centre pier on the down stream side, being anchored to bed rock and built strong enough to carry the girders under traffic. A light trestle was erected between these cluster bents 18 feet from the main track centre to centre, and a spur with a capacity of three cars was built north of the bridge, the fill being widened for the purpose. When the girders were received the four cars were set on this spur and the girders unloaded and placed with cribbing and jacks on the new masonry and the cluster bents. The division derrick car worked on this track under its own power, placing the floor beams and stringers and removing the light trestle as it receded. The riveting and flooring of the girders were then completed and the fill was widened south of the bridge so that the main track could be carried around the old bridge over the new girders. This track was used at a speed of 10 miles an hour during the dismantling of the old truss. As the derrick car had the freedom of the old main line for the dismantling work there was no necessity for the use of travelers or work trains. The trestle that had been removed from the run-around was driven under the old truss to support it during dismantling. When the truss had been removed and the bridge seats finished to conform to the masonry plan, the girders were moved sidewise into place between trains and the main track restored to its original location. While this work was under way there were two floods, clearing the stream of heavy ice, and on neither occasion was there any false work in the channel to obstruct the flow. This work was done under the direction of D. B. Johnston, division engineer to, whom we are indebted for this information.

PANAMA CANAL BILL MAY HELP CANADIAN RAILWAY.

Without intending it, the Panama Canal bill in its present form may give enormous advantage to the Canadian Pacific Railway, thinks the Wall Street Journal. Ownership of ships by the railroads of the United States trading through the canal is extinguished, while the Interstate Commerce Commission is given power to regulate ships trading elsewhere so owned. But it is diplomatically impossible, on all construction of international law, for this country to decree the ownership of foreign vessels using the canal. This necessarily gives the Canadian Pacific an enormous advantage, in the ownership of its fleet, over the Southern Pacific or the New Haven, to say nothing of its competitors in the North-West with no ships at all.

This advantage would be emphasized by the possibility of retaliation by Canada in the matter of its own ships canals, which would not be subject to the question of discrimination in favor of our own coastwise trade through the Panama Canal. The American tonnage through the Canadian canals is 18,250,000, as against 1,118,000 for Canadian vessels. A preference to the latter would be of far-reaching consequence, and would, of course, help all the Canadian railways.

AN INTERESTING REPORT ON DESTRUCTION OF REFUSE.

Mr. James Bee, superintendent of the Street Cleaning Department of Blackpool, England, in his annual report states that the quantity of refuse dealt with at the destructor last year amounted to 18,372 loads, the weight of which was just over 18,943 tons. This quantity, though considerably below last year with regard to the number of loads removed, is only a slight decrease as regards tonnage, the figures for 1910-11 being 18,734 loans and 19,000 tons. The difference is accounted for by the carts taking larger and heavier loans.

There has again been a slight reduction in the cost of dealing with the town's refuse, which during the year averaged 1s. 0¾d. per ton, whereas the average cost per ton for the previous year was 1s. 1d. It is worthy of note that the cost has gradually decreased from 1s. 6½d. per ton in 1906-7.

Profits from By-Products.—There is, it appears, a steady increase shown in the profit-earning by-products.

"I have pleasure in being able to report," says Mr. Bee, "that the tremendous increase which has taken place within the last half-dozen years in the revenue from the sale of by-products at the destructor has been maintained. During the year the unprecedented sum of £1,660 was derived from this source, an increase of £55 on the income obtained from last year's sales. To show the wonderful possibilities which lie in what is apparently the waste material of the town, it is only necessary for me to point out that during the year 1904-5 we were deriving what was then considered the respectable sum of £248. We have thus increased our revenue in eight years by £1,412."

A table of statistics shows how the money is obtained. Compared with 1910-11, there are considerable decreases in the sale of ashes and clinkers and mortar, but the yield from fish manure has risen from £558 to £815, which brings about the total increase. During the year 2,327 loads of ashes and clinkers were disposed of, a decrease of 782 loads, which represents a loss of revenue of £102. The quantity of mortar manufactured was 1,490 tons, or 570 tons less than last year, which created a record by bringing a revenue of £470. This year the amount was £330.

Dust Collection.—The work of removing the town's refuse has again been carried out in a satisfactory manner, a daily collection having been maintained in connection with the hotels, hydros, restaurants, and the larger boarding-houses; while from the ordinary company-houses the refuse has been removed from two to three times weekly. All other premises have had attention weekly.

[illegible] large and [illegible] medium galvanized [illegible] cost price, to replace the less sanitary wooden receptacles.

[illegible] the beginning of the year, of [illegible] to be collected by private enterprise, [illegible] by the corporation.

[illegible]

carting 3s. 5¼d. per ton, making a total of 5s. 5¾d., an increase on last year of ¾d., accounted for on carting.

Street Cleansing.—The system of collecting street sweepings by means of orderly trucks has been so successful that six additional trucks have been obtained. On the Promenade and in the main thoroughfares men are continually at work. During the past year, for instance, Bank Hey Street was swept no fewer than 4,181 times. All the principal streets are swept from ten to twelve times daily. The less important thoroughfares receive attention daily, and the back streets weekly.

The quantity of sweepings removed during the year shows a large increase, 4,969 loads having been removed by the carts, and 38,237 bins by the orderly trucks, making a total of 8,155 ordinary cart loads, this number being an increase of 485 loads on last year. The corporation carts engaged on this work were employed for 10,306 hours, and were supplemented on 2,447 hours by hired carts, making a total of 12,753 hours. Last year the total was 11,814 hours. The streets swept within the borough during the year amounted to approximately 100 miles.

The expenditure in wages for carrying out the work of street sweeping for the year has been £6,777 for labor, and £713 for team labor and horse hire, a total of £7,490. This is an increase of £305 on the previous year, when £7,185 was expended. This does not include washing streets. The cost per mile has been £74 18s.

During the twelve months washing operations were carried out by the carts on 72 days. The water used amounted to 640,500 gallons, of which 15,050 were fresh water, and the remainder salt water.

In four days in January 1,209 loads of snow were taken away, at a cost of £108. The cost per load works out at 1s. 10d., or 1s. 2d. for labor and 8d. for carting.

It was necessary to grit or sand the streets on 184 days, compared with 211 the previous year.

Street Watering.—Mr. Bee adds: "During the past summer the utility of the new salt water main extensions was very early demonstrated, for during the prolonged drought, when we were prohibited from using fresh water, a plentiful supply of salt water was available, and this enabled us to water the streets without any restriction whatever. Moreover, this work can be done more efficiently and economically by using salt water, for after a road has been watered with it consecutively for three or four days it is practically dustless, even to the fastest motor car. Its deodorizing properties are also a factor in support of its use, not only for street watering, but for flushing gullies and sewers. The salt water mains have now been extended so as to make us entirely independent of fresh water."

Street watering operations were carried out on 162 days. The quantity of water used amounted to 4,898,250 gallons, of which 3,975,300 gallons were salt and 922,950 fresh water. No fresh water was used after the beginning of June. As showing the economy of using salt water, last year the total consumption was 5,056,250 gallons. Fresh water used was 2,129,150 gallons, and salt water 2,927,100 gallons. The quantity of water used last year was the lowest on record. The cost of street watering was £[illegible], or £[illegible] per mile.

◆

SHAWINIGAN POWER COMPANY.

Shareholders of the Shawinigan Water and Power Company will be asked at a meeting called for September 3rd to authorize the issue of $[illegible] additional capital. The authorized capital stock of the company is at the present time $[illegible], of which $10,000,000 remains unissued.

ELECTROLYTIC ACTION ON UNREINFORCED CONCRETE.

In a brief paper before the International Association for Testing Materials, Mr. Cyril de Wyrall, Chief Inspector, Interborough, Rapid Transit Co., New York City, cites observations indicating the destruction of plain concrete by electric currents. We abstract a portion of his remarks as follows:

Four years ago an inspection was made of a concrete wall, which was erected in 1902. This wall, which carried no load, is below tide level, is 3 ft. thick, and is made of 1:2:4 mixture of cement, sand and trap rock. It was placed with care and under competent superintendence. The examination showed a disintegration to such an extent that the surface was practically mush. A year later another examination was made, and large sections, from 4 to 6 ins. thick, which crumbled in the hands, could be pulled off the face Last year still further deterioration was found to be in progress, and a chisel could be driven 12 ins. into the wall by hand alone. A voltmeter test showed that current under 11 volts pressure was passing through this structure. It was believed at the time of the second examination that the "failure" was due to the action of salt water alone, and no test was made for stray electrical currents until lately.

This is not an isolated case. There is an exact duplicate in almost every particular, except that the latter structure was erected a year later and different brands of cement were used. In the summer of 1911 the writer made an inspection of some concrete tunnels and bridges erected by three different railroads entering New York. This work has been only recently finished. Each of the railroads had its own cement laboratory, and the different brands of cement used were rigidly tested. The structures are all above tide level, and wet only in spots. Where the concrete is wet, from one to five volts was found, and the concrete is deteriorating, though not as much as in the former instances. Where the concrete is dry no voltage was found and the concrete is in excellent shape; this occurs in the same tunnel. the concrete apparently being the same mixture and placed at the same time. It seems to make no difference whether the concrete was placed in cold or warm weather, deterioration goes on just the same, the only difference being between the wet and dry places.

It is a known fact, although wet concrete is an excellent conductor, dry concrete is practically a non-conductor. The combination of electric current and water seems to act as a disintegrating agent on the cement, destroying its cohesion and reducing it to a paste, which when dried can be pulverized with the fingers. This condition demands immediate remedial measures, or serious trouble will undoubtedly ensue.

It is only the effects, which careful and continuous examinations have shown, which are brought to your attention. One efficient means of preventing the damage may be mentioned, however: waterproofing thoroughly all parts of a concrete structure that is surrounded by earth. Such protection acts in two ways; it keeps the structure dry and it insulates against electric currents.

ABITIBI PULP LIMITS SOLD

Greater activity is evidenced in the development of Northern Ontario. Settlers are entering the country more rapidly, but are not likely to patronize that region in large numbers until the advent of ready made farms. Messrs. Shirley Ogilvie and F. H. Anson of Montreal, are the successful tenderers for the Abitibi pulp limit offered by the Ontario Government. The amount of the bonus to be paid to the government is $5,000 per year, distributed over a period of twenty-one years, making $105,000 from this source alone. This represents only the right to cut pulpwood and timber on the limit, which comprises 1,560 square miles, and entitles the successful tenderer to obtain a lease, upon the usual terms, of Iroquois and Couchiching Falls for power purposes.

An additional undertaking, not required by the government, which Messrs, Ogilvie and Anson have inserted in their offer, is that during and after 1913 they will advance for the purpose of being expended or shall expend $50,000 in preparing buildings and land for settlers in the neighborhood of Iroquois Falls. None of the land on the limit goes with the lease, so the conditions under which this money is to be expended will be decided by the Minister of Lands, Forests and Mines, although a lien will be retained on all property sold until the purchasers repay the amount on each farm in easy instalments.

The tenderers also agree to buy wood and agricultural products from the settlers and covenant to promote as far as in their power the development and settlement of the district.

A joint stock company with a capital of $1,500,000 is to be organized to carry out the enterprise.

An integral part of the scheme is the construction of a pulp mill costing, with equipment and machinery, not less than $500,000, with a daily output of one hundred tons of pulp and the employement of two hundred and fifty-nine hands on an average for ten months in the year. This investment is distributed—$100,000 during the first year; $200,000 during the second year; and the balance during the third year. Cutting may commence on the limit so soon as $100,000 is expended on the mill.

The successful tenderer is also under agreement to erect a paper mill on the order of the Lieutenant-Governor in Council, which shall have a capacity of one hundred tons of paper per day and shall turn out not less than seventy-five tons of paper per day.

Another likely development is the starting in Northern Ontario of a system of forest industries, employing trained men and operated upon lines that will mark a departure from the wasteful lumbering methods of the past. Negotiations are proceeding by which, it is expected, a large area in the north will be secured by private interests and devoted to the making of wood products that will utilize every inch of the trees from roots to top. With it will be carried on reforesting and the scientific culture of existing timber.

Mr. F. L. Barledt, a British capitalist who controls similar industries in Germany and Russia and is interested largely in a number of enterprises in England is behind the project. Mr. Barledt is in Toronto awaiting the outcome of the negotiations. Although a British citizen he is German born.

NEW PUMPS AT WELLAND, ONTARIO.

The pumps at the new pumping station at Welland, Ontario, have recently been put into service. The pumps were constructed by Messrs. Frank Pearn and Company, Limited, Manchester, England, and supplied by the Canadian Boving Company, Bay Street, Toronto. The water wheel is designed for the following:—Net head, 7 feet; normal output, 200 brake horse-power; maximum output, 250 brake horse-power; normal speed, 58 revolutions per minute.

THE CLEANING OF WATER MAINS.*

By F. W. W. Doane, City Engineer, Halifax.

The injunction from the secretary, limiting the extent of these discussions to one thousand words, makes it very difficult to deal fully with this important subject.

On the inside of all water supply pipe which has been in use for any length of time, there will be found an incrustation of oxide of iron more or less heavy. This coating presents a very rough surface compared with the original finish. It consists of tubercles or blisters shaped like a rivet head and varying in size, between which is an accumulation of sediment or ferruginous slime which greatly reduces the internal diameter and consequently the discharging power of the pipe. In some cases the discharging and carrying capacity of the pipe is reduced more than 50 per cent. and the thickness of the incrustation varies from ½ inch to 1¼ inches.

This incrustation has been removed annually from the pipes supplying the city of Halifax ever since 1880, by a mechanical scraper forced through the main by the pressure of water.

The scraper used there consists of two distinct portions, the front portion carrying the steel scrapers and the rear propelling the machine. There is a stout centre rod of wrought iron in two pieces, coupled together in such a manner as to allow a little play, so that the machine may pass round and bend or angle in the pipe line. There are eight arms of spring steel varying in width and thickness according to the diameter of the pipe, arranged in two sets of four each, the set behind breaking joint with that in front, so as to effectively scrape the entire inner circumference of the pipe. Each spring has a cutting edge tapered towards the centre of the pipe with the double object of cutting or splitting longitudinally any heavy incrustation of iron rust, and also of preventing the barbed knife from catching in any valve or defective or open joint in the pipes which would also cause a stoppage. A ferrule or similar obstruction striking the knife will cause the scraper to turn partially round and thus pass the obstruction without getting blocked, or the springs will yield sufficiently to enable it to pass.

The pistons or discs do all the work in propelling the machine forward. They are made double in order to insure steadiness, and they do not do any cutting work whatever. The discs are of iron, somewhat smaller in diameter than the the bore of the pipe, so that water may pass them to wash out the accumulated scrapings cut away. The iron [illegible] by radial cuts and stiffened at the back by lead plates, their construction giving them sufficient stiffness to withstand the pressure [illegible] backwards to pass any obstruction not removed by the cutters. In large sizes, small springs are attached to the back [illegible] exactly in the centre of the pipe. This is necessary with the large scrapers on account of their great weight. They also preserve the leather discs from being worn out too [illegible]

[illegible] in contact with the metallic iron through minute defects in [illegible] a knife after the tubercle is removed. The action of chemical salts and substances which form marsh land, and the salt water, corrode the iron rapidly from the outside and soften it in the same manner as the corrosive action referred to above, on the interior.

To prepare for cleaning, a section of pipe must be removed at each end of the main to be cleaned. The scraper is inserted, the section of pipe replaced, and the water turned on. The scraper starts off with a rumbling noise, by which it can be easily followed by men running along the pipe line. The rate of speed varies from ¼ of a mile an hour on the flat ground under a small head of water or going up a hill, to six miles an hour or faster, going down a hill. Where there are hydrants or blow-offs, they are left open and the approach of the scraper may be detected first by a current of air, followed by a rush of water which has accumulated in front of the machine. The water turns to a dirty brown color and as the scraper passes, the water becomes black. After the passage of the scraper, if the water is allowed to run from the hydrant, it gradually becomes clearer. It is out custom, however, to close the hydrants at once after the scraper passes, so that the pressure behind it may not be reduced.

In the city of Halifax the greatest length of pipe cleaned in one day is a supply main in two sizes, 15-in. and 20-in., and seven miles in length. It has been the custom to clean this main three times a year, while the other supply main is cleaned once a year only, and distribution mains when required. The first cost of cleaning the first twelve miles of mains over 30 years ago, averaged 3½ cents a foot for everything, including manholes, the lowest cost being 1⅔ cents and the highest 7 1/5 cents. The average cost, not including manholes was 2 8/10 cents.

Twenty-nine thousand five hundred feet of 15-in. main has been cleaned in 95 minutes, and the whole seven miles at a cost of $8.30, or 3/100 of a cent a foot. The lowest head operated under is 11 ft., but cleaning could not be done under such conditions except by an experienced man The heaviest incrustation removed is 1¼ in. from a pipe which had been laid between 30 and 40 years and was uncoated, while a 1-in. pipe has been closed in four years.

The cost for re-cleaning supply mains during 25 years was 1/16 of a cent per foot. On one occasion they were cleaned for 1/20 of a cent. Cleaning distribution mains is a little more expensive and varies from 1/10 of a cent to ½ cent a foot. The cost of cleaning by hand, before the mechanical scraper was used, was 14 2/10 cents per lineal foot.

Some of the immediate results were that the average pressure on 25 hydrants increased from 34.2 lbs. in February of one year, to 54.4 lbs. in February following, or 53 per cent. In another district there was a pressure of 19 lbs. after the cleaning, on hydrants where in the previous year there has been no water at all. In one cleaning an improvement of 400 per cent. was obtained, while at Louisville, Kentucky, they claim an improvement of 654 per cent. in one case.

The cleaning in Halifax has saved the city a large expenditure, the cost averaging about $3.25 a mile, while if it had not been possible to clean with a mechanical scraper, most of the mains would have been renewed long ago at a cost of many thousands of dollars.

◆

Contracts have just been let by the Montreal Transportation Company by which the Canadian canal trade will have the first electrically propelled merchant vessel ever built. The principle of propulsion for this vessel is identical with that of the "Gas Electric" railway car, of which an example was recently seen in Toronto on the line of the Canadian Northern.

---

*[illegible]

CANADIAN PACIFIC'S EXPANSION

The increase in the capital of the Canadian Pacific Railway, noted in last week's Monetary Times, and which will shortly be made, again draws attention to a railroad which has loomed large in the international investment eye. The increase will be from $200,000,000 to $260,000,000. There is little doubt as to the need of increased funds by the Canadian Pacific. It has a long programme of construction ahead, the most important part of which, perhaps, is the double tracking of the road to the Pacific Coast. Both passenger and freight traffic is rapidly increasing, and within a few years there will be work and constant use for a double track. Expansion of the company's hotel and steamship services, both of which have proved remunerative and in both of which there is room for expansion, will probably occur.

While it was not intended, the news of the new stock issue became public shortly after the publication of the company's preliminary statement for the year ended June 30th. It shows record earnings and constitutes a fairly good index to trade conditions in Canada to-day. The gross earnings by the railway and its allied steamship lines, with the working expenses, for 1911-12 and the six preceding years are given below:—

	Earnings.	Expenses.
1911-12	$123,319,541	$80,021,298
1910-11	104,167,808	67,467,977
1909-10	94,989,490	61,149,534
1908-09	76,313,320	53,357,748
1907-08	71,384,173	49,591,807
1906-07	72,217,527	40,914,218
1905-06	61,669,758	38,696,445

In six years the operating income of the railway and its properties has doubled, the operating expenses having rather more than doubled. This showing has been made during a period of increased competition, and in face of a tendency to reduce rates, for carrying both passengers and freight.

The company's dividends have been steadily maintained and the shareholder naturally has every confidence in their maintenance. It would be a disaster beyond modern foresight that would cause the passing of the Canadian Pacific Railway dividend. Invariably, too, the company has been able to report a large surplus after the payment of all dividends. Commenting on that fact, the London Statist reminds us that the company could stand a shrinkage in its traffic and gross earnings of something like 25 per cent. before the profit would cease to be sufficient to provide the 10 per cent. dividend. A shrinkage of 25 per cent. in traffic and in earnings is a very large sum, and that to have a margin of this kind indicates the conservative manner in which the company's financial policy is controlled.

There is an idea that a further increase of dividend to a still higher basis than 10 per cent. may take place, but those persons who expect an increase in distribution would do well to remember that it is wiser to pay a dividend which the company can maintain in good and bad years alike, than to distribute a dividend which would have to be seriously cut in a time of depression, or which could not be maintained in a period of increased competition.

◆

The interests representing the Labrador Pulp and Power Company have decided on a large pulp and paper enterprise, involving the increase of the capitalization of the company from three millions to fifteen millions of dollars, stated Mr. Robert H. Reid, of New York, vice-president of the company.

WILL THERE BE A CAR SHORTAGE?

That a car shortage is imminent is the opinion of Mr. J. E. Walsh, transportation manager of the Canadian Manufacturers' Association. An estimate based on railroad figures of the past four years tends to show that shippers will be confronted with a car shortage of sixty thousand this year on the smallest possible estimate, and as great a deficit as 180,000 cars should the proportion be as high as it was in October, 1909.

Vice-President Bury, of the Canadian Pacific Railway, said that so much has been done in preparation for handling the crop by concentrating rolling stock and motive power, together with the earliness of the season, it is improbable that there will be any blockade.

◆

RAILROAD EARNINGS.

The following are the railroad earnings for the week ended August 7th:

	1911.	1912.	Increase or decrease.
C. P. R.	$2,272,000	$2,706,000	+ $434,000
G. T. R.	1,017,982	1,109,682	+ 91,700
C. N. R.	332,500	407,300	+ 74,800
T. & N. O.	35,274	30,905	— 4,369
Halifax Electric	5,641	5,646	+ 5

The following are the railroad earnings for the week ended August 14th:

	1911.	1912.	Increase or decrease.
C. P. R.	$2,205,000	$2,677,000	+ $472,000
G. T. R.	1,048,062	1,098,423	+ 50,361
C. N. R.	319,700	401,800	+ 82,100
T. & N. O.	36,830	29,838	— 6,992
Halifax Electric	5,714	6,486	+ 772

The accounts for the Grand Trunk Railway Company for the half-year to the 30th of June, 1912, show the following results:

Gross receipts		£3,834,300
Working expenses		2,793,300
Net receipts		£1,041,000
Deduct debit balance on account of rentals, outside operations and car mileage		33,500
Total net revenue		£1,007,500
Net revenue charges for the half-year, less credits		513,900
Balance		£493,600
Deduct Canada Atlantic deficiency for the half-year	£52,800	
Detroit, Grand Haven & Milwaukee deficiency for half-year	50,700	103,500
Surplus		£390,100

This surplus of £390,100 added to the balance of £6,800 from December, 1911, makes a total amount of £396,900 available for dividend, which will admit of the payment of the full dividend for the half-year on the four per cent. guaranteed stock, and first and second preference stocks, leaving a balance of about £8,500 to be carried forward.

The accounts of the Grand Trunk Western Company for the year ending 30th of June, 1912, after providing for all fixed charges, including the debit balance of £31,461, brought forward from the previous year, show a deficit of £16,144, which will be carried forward to the current year.

ENGINEERS' LIBRARY

Any book reviewed in these columns may be obtained through the Book Department of The Canadian Engineer.

BOOK REVIEWS.

Reference Book for Statical Calculations.—By Francis Ruff; published by Constable & Co., London. Cloth; 5 x 8 ins.; [illegible] illustrations; 136 pages; price $1.25.

This book is the translation of the German volume of the same name. It contains, in shape for rapid use, force diagrams for frame works, tables, instructions for statical calculations for all classes of building and engineering. The different application of statics to engineering design is presented in a comprehensive and clear manner. The use of the book should be conducive to carrying out any desired statical calculations with ease and rapidity. A compendium of tables at the end of the work includes tables for timber, weights of railway bridges and street bridges, weights of various materials, specific weights and loads used in building, etc. These tables will certainly spare the owner of the book a great deal of labor. The volume is intended as a reference book purely. It should be in the hands of every engineer and architect, for as a ready reference book on statics, it is the best we have seen.

Reinforced Concrete Construction.—By Geo. A. Hool; published by the McGraw-Hill Book Co., New York. Cloth; size 6¼ x 9½; first edition; 250 pages; price $2.50.

This is another volume of the Engineering Education Series, prepared in the extension division of the University of Wisconsin, for the use of their students in the correspondence courses. Vol. I. of Reinforced Concrete Construction deals with the fundamental principles of concrete construction and design and includes numerous tables and diagrams to facilitate the calculation and design of reinforced concrete structures. The book presupposes a knowledge of the elements of structures and is written to meet the needs of those who desire to take up the study of the subject by correspondence. There appears to be no reason, however, why it should not be employed for other purposes. The complete text for the course in reinforced concrete construction will be in three volumes, of which this is the first. The ground [illegible] design of retaining walls and building, but omits, however, the flat slab type of floor construction, which will be taken up in Vol. II. The treatise is most clearly written and the dis- [illegible] followed.

Concrete Workers Reference Books.—Published by the Norman W. Henley Publishing Co., 132 Nassau Street, New York. [illegible]

[illegible] constructor.

Diary of a Roundhouse Foreman.—By Mr. T. S. Reilly; published by the Norman W. Henley Publishing Co., 132 Nassau Street, New York. Cloth; 5 x 7; 158 pages; price $1.00.

This little volume is a compilation of a series of articles by the author which were published in the "Railway and Engineering Review." It contains many suggestions in connection with the duties of a roundhouse foreman, and much of the material for the book was obtained while the author occupied the position of machinist, roundhouse foreman and superintendent of motive power. It is a most interesting little volume and will be read by the railroad man with a good deal of pleasure.

Metropolitan Water Board: Eighth research report on the softening, purification and sterilization of water supplies. By Dr. A. C. Houston, director of water examination.

In his seventh report Dr. Houston mentioned that he had found that one part of quicklime added to 5,000 parts of raw river water was capable of killing B. coli in from five to twenty-four hours. The Water Board are in the position of being unable to purify all the water required in London by the method they prefer, viz., storage. Dr. Houston has set himself the task of finding out if his discovery with regard to the effect of quicklime will help the Board out of the difficulty, and tells his story in this his eighth report. To the treatment he gives the name of "Excess Lime Method," and briefly he finds that when one part of quicklime (about 75 per cent. CaO) is added to 5,000 parts of raw Thames water, about .007 per cent. free CaO is left in the mixture, and this excess is sufficient to kill B. coli in from five to twenty-four hours. To neutralize the excess, not less than 25 per cent. of store water must be subsequently added. The resulting fluid is water which has been purified ("placed beyond the pale of epidemiological criticism"), clarified and softened. On the question of softening Dr. Houston is led into a most interesting discussion as to the relative advantages of hard and soft waters. On health grounds he believes that there is absolutely no reason for objecting to hard water. On grounds of economy there are reasons, though they are, after all, not serious. The furring of boilers and pipes and consequent loss of heat is perhaps the most important, but the wastage of soap is largely a theoretical objection. For these reasons he does not believe that in the case of London water, at any rate, it is worth while incurring expense in providing plant, etc., and purchasing quicklime for softening purposes only. If in addition you can purify the water without the necessity of storing more than a fourth of all that is required, it is worth while. Quite satisfied with the method, Dr. Houston recommends it to the Water Board as a way out of their difficulties. Apart from mentioning that the quicklime [illegible] per pound, and that the London County Council [illegible] per annum at the sewage outfalls, got it for 13.75 shillings a ton in 1910, the financial side of the question is not entered into much. The [illegible] must be estimated by engineers, financiers, etc. The report itself, however, is, as is usually the case with Dr. Houston's reports, intensely practical and interesting, and the experiments are clearly described. The work marks a tremendous advance in our knowledge of water purification.

Pumping and Water Power.—By F. A. Bradley; published by E. F. Spon, 123 Liberty Street, New York; size 6 x 9; 120 pages; price $1.50.

The book was written by a consulting engineer, and although many works have been written embracing the subject of hydraulic work, pumping appliances, and the application of hydraulic power, they usually treat of some especial feature or branch of the subject, or of mechanical details of construction, or the book is too costly to be within the reach of mechanics, students, and others to whom a general explanation of the laws of hydraulics and their practical application would be serviceable. The present treatise will meet a necessity in this respect.

The work includes chapters on important laws of hydraulics, atmospheric pressure, pumping work, suction pipes, units of work, steam pumping, centrifugal pumps, hydraulic power machinery, hydraulic rams, waterwheels, turbines, pelton wheels, water pressure engines, and well boring.

And ten tables which includes areas of circles, square cubes, square roots and cube roots, loss of pressure by friction in pipes, weight of water at different temperatures, weight and quantity of water in one foot of pipe, average pressure of expanded steam, volume of steam at various pressures, theoretical velocity of water, downward flow turbines and pressure of water.

The book is well illustrated and a study of its contents should assist those engaged in erecting or using hydraulic machinery to lay out their work with confidence.

Webster's New International Dictionary.—Published by G. and C. Merriam & Company, Springfield, Mass. Leather; 9 x 12 ins.; 2,620 pages; profusely illustrated; price $12.

This new dictionary of the English language, which is based on the International Dictionary, of 1890 and 1900, is now completely revised in all departments. The new edition includes a dictionary of geography and biography. The first edition contained 70,000 words; this edition contains 400,000 defined words and phrases. Among the interesting features are the divided page, an up-to-date gazetteer and biographical dictionary, and 6,000 illustrations, many of them in color. This dictionary should be in the hands of every professional man.

PUBLICATIONS RECEIVED.

Proceedings of the Royal Military College Club of Canada. Editor, Lieut.-Col. Ernest F. Wurtele.

Commercial Creosotes. With special reference to wood from decay. By Carlisle P. Winslow. Being Circular 206 of the Forest Service, U.S. Department of Agriculture.

The Effects of Cold Weather upon Train Resistance and Tonnage Rating. By E. C. Schmidt and F. W. Marquis. Bulletin No. 59, University of Illinois, Engineering Experiment Station, Urbana, Ill. Price 20 cents.

American Road Builders' Association. Proceedings of the eighth annual convention, held at Rochester, N.Y., Nov. 14-17, 1911. Published by the association, 150 Nassau Street, New York. Price $1.00.

Forest Products of Canada, 1911—Pulpwood. Compiled by H. R. Macmillan, B.S.A. Bulletin No. 30, Forestry Branch, Department of the Interior.

Report on Mining Operations in the Province of Quebec During the Year 1911. The Mines Branch, Department of Colonization, Mines and Fisheries, Province of Quebec.

Seventh Report of the Bureau of Archives for the Province of Ontario. By Alex. Fraser, Provincial Archivist, Toronto, Ont.

Mica; Its Occurrance, Exploitation and Uses. Second edition, by Hugh S. de Schmidt. Mines Branch, Department of Mines, Ottawa.

Diamond Drilling at Point Mamainse, Province of Ontario. By Alfred C. Lane, Ph.D. Bulletin No. 6, Mines Branch, Department of Mines, Ottawa.

The Metropolitan Water Board. Eighth report of research work, by Dr. A. C. Houston, on the softening, purification and sterilization of water supply. Metropolitan Water Board, London, E.C.

Queen Victoria Niagara Falls Park. Twenty-sixth annual report of the commissioners. Copies may be secured from the superintendent, J. H. Jackson, Niagara Falls, Ont.

The Fifth Census of Canada, 1911. Vol. I., containing areas and population by provinces, districts and sub-districts. Department of Trade and Commerce, Ottawa.

Tenth Report of the Geographic Board of Canada for year ending June 30th, 1911. Being supplement to the annual report of the Department of Marine and Fisheries, Ottawa.

Third Annual Report, Commission of Conservation of Canada. The report of the third annual meeting held at Ottawa, January 16th, 1912. James White, secretary, Ottawa.

The Canada Year Book, 1911. Second series. Ottawa, Ont.

Ottawa Improvement Commission. The report and correspondence of the Ottawa Improvement Commission relating to the improvement and beautifying of Ottawa. Ottawa, Ont.

Telephone System. The Ontario Telephone Act. Municipal Ownership of Rural Telephone System, by Francis Dagger, Toronto, Ont.

Annual Report of the Minister of Mines, British Columbia, for the year ending 31st December, 1911. Being an account of mining operations for gold, coal, etc., in the province of British Columbia.

Preliminary Report on the Clay and Shale Deposits of the Western Province. By Heinrich Ries and Joseph Keele, being memoir No. 24 E Geological Survey Branch, Department of Mines, Ottawa.

Chain Belt. Paper, 6 x 9 ins., 8 pages. Chain Belt Co., Milwaukee, Wis. This is the August number of "Chain Belt," and it contains a descriptive article of the method adopted for roundhouse construction on the Lake Shore & Michigan Southern R.R. at Chicago, by means of the shooting system and movable steel towers 72 feet high.

CATALOGUES RECEIVED.

Wire Rope and Fittings. The B. Greening Wire Company, Limited, Hamilton, Ont., forward catalogue illustrating their wire rope and rope fittings.

Lead Wool. How to Use It. Pamphlet issued by the United Lead Company, 111 Broadway, New York, describing the use of lead wool.

Green's Fuel Economizer. Catalogue No. 142, forwarded by the Green Fuel Economizer Company, Matteawan, N.Y., describing different installations of the economizer.

Stokers. The American Stoker Company, 11 Broadway, New York, forward Bulletin B-I entitled "The Class 'E' Stoker," describing their new underfeed type of stoker.

Patent Steel Pipes. Stewart's and Lloyd's, Limited, Glasgow, forward catalogue describing the Stewart patent steel pipes.

Herringbone Gears. The Earle Gear and Machinery Co., Philadelphia, Pa., forward pamphlet describing their Herringbone gears.

Motor Trucks. The Canada Foundry Co., Limited, forward pamphlet illustrating the Knox-Ajax trucks for commercial use.

Industrial Railways. Catalogue No. 12-1, issued by the C. W. Hunt Company, West New Brighton, N.Y., illustrating Hunt industrial narrow gauge railways for handling raw and finished material.

Hayward Buckets and Digging Machinery. Being pamphlet No. [illegible] issued by the Hayward Company, 50 Church Street, New York, illustrating the use of their buckets and digging machinery.

Continuous Current Dynamos and Motors. Bruce Peebles and Co., Limited, Edinburgh, forward catalogue illustrating their medium size, self-contained continuous current dynamos and motors.

Gutta Percha India Rubber Covered Wires. The India Rubber Gutta Percha and Telegraph Works Co., Limited, London, E.C., forward price list of Gutta Percha India Rubber silk and cotton covered wires.

Mesta Machine Company forward 5 x 7-inch pamphlet, being a brief description and illustrations of their plant and products. Copies may be secured by addressing the Mesta Machine Company, 1245 Oliver Building, Pittsburg, Pa.

Glover's Cables. Descriptive catalogue and price list of cables for electric lighting, power and traction purposes. Manufactured by W. T. Glover & Co., Limited, Trafford Park, Manchester. Being List No. 4, Mains Section.

Westinghouse commutating pole direct current motors (Type QM) for compressors, blowers, pumps, and similar classes of service are fully illustrated and described in leaflet 2499, issued by the Westinghouse Electric Manufacturing Co.

Rules for the Selection of Machine Tool Motors, is the [illegible] by the Westinghouse Electric and Manufacturing Co. Quite a lot of valuable information is here condensed into a small space relative to the selection of a motor with the proper characteristics for the desired duty.

Faessler's Safety Sectional Expander with Quick-Acting [illegible] just published by the J. Faessler Manufacturing Co., Moberly, Mo. This bulletin illustrates and describes a new sectional expander which eliminates side blows on removal of the mandrel, [illegible] in time.

Circular 1516, attractively bound in an art cover, has [illegible]

Switchboard Meters [illegible] complete line of switchboard meters recently brought out by this company. In addition to describing and illustrating these meters, the circular contains reprints of papers by Mr. Paul McGahan on (1) Modern Tendencies in the Design of Switchboard Indicating Meters, and (2) Theory and Performance of Induction Instruments.

The Westinghouse Electric and Manufacturing Co. has just issued a series of descriptive leaflets (Nos. 2465 to 2473) illustrating the new line of switchboard seven and nine-inch indicating meters. In each leaflet is a full-sized facsimile of the meter dial, the purpose being to present a correct idea of the actual appearance of the meter when installed. By placing these leaflets on the wall an accurate idea of the readability of the meter may be gained from any distance and angle.

Descriptive Leaflet No. 2494 issued by the Westinghouse Electric and Mfg. Co., fully illustrates and describes the Westinghouse synchronous booster rotary converter. This machine consists of a standard converter in combination with a revolving armature alternating current generator mounted on the same shaft with and having the same number of poles, as the ammeter by means of which the direct current voltage delivered may be varied.

Sewage Distributors. Through the courtesy of Messrs. Laurie and Lamb, 211 Board of Trade, Montreal, we have received a copy of the new 140-page catalogue issued by Messrs. Tuke and Bell, Limited, of London, England, for which firm Messrs. Laurie and Lamb are sole agents for Canada. The catalogue which is bound in stiff covers, illustrates and describes various types of sewage sprinklers, distributors, ejectors, centrifugal pumps, penstocks, sewage screens, and many other pieces of apparatus of general interest to municipal engineers and of specific interest to those who have to do with the construction and maintenance of sewage disposal equipment. We would advise those interested to write Messrs. Laurie and Lamb for a copy of the catalogue.

The following two letters are fair samples of many letters which reach our office almost daily.

Toronto, Ontario,
August 20, 1912.

The Canadian Engineer,
Toronto.

Gentlemen,—I have yours of August 15th re the.......... advertisement and subscription. I certainly would not or could not do without your paper, but you will have already received notice from the ....Head Office ordering the paper to be sent to me

Yours very truly,

....
Consulting, Designing and
Inspecting Engineer.

St. John, N.B.,
August 15th, 1912.

The Canadian Engineer,
Toronto.

Gentlemen,—Kindly send my copies of The Canadian Engineer [illegible] St. John, N.B., [illegible] weekly paper [illegible]

Yours truly,

Civil Engineer.

CANADIAN FAIRBANKS-MORSE TO BUILD TRACTOR FACTORY.

Messrs. T. Pringle and Son, Ltd., engineers and architects, Montreal and Toronto, have prepared designs for a large modern tractor factory to be erected on the south end of the property of the Canadian Fairbanks-Morse Company, Limited, Bloor Street, Toronto. The building will be 397 feet long by 100 feet wide, and will consist of concrete foundations with structural steel framework and brick walls. Steel sash will be used throughout for all windows. The forge shop will be 122 feet by 49 feet; testing room, 76 feet by 49 feet; erecting shop, 172 feet by 49 feet; structural steel shop, 318 feet by 49 feet, and the tin shop 397 feet by 49 feet. The structural steel shop will be served by two one-ton cranes and the erecting shop by a 12-ton crane. A very complete system of industrial railways will serve all portions of the plant. The paint shop is to occupy the end of the erecting shop, and it is from here that the tractors will be loaded directly into the cars on the siding. The factory will cost about a quarter of a millian dollars and will be, when completed, one of the finest equipped plants in the world for the manufacture of tractors.

◆

INCREASED WORK OF TORONTO'S NEW CIVIC LABORATORIES.

The laboratories of the Medical Health Department of this city were recently moved from very cramped quarters to spacious rooms and the results from the increased facilities is well shown by the following statistics.

In all, 2,385 specimens have been examined, as compared with 1,420 in July, 1911, as follows.—

	July, 1911.	July, 1912.
Diphtheria cultures	861	634
Tuberculosis sputum	46	106
Typhoid blood	49	39
Gonorrhœa	8	7
Water specimens	104	343
Milk for bacteria	152	284
Milk cans for bacteria	...	121
Milk for fat	200	423
Milk for dirt	...	428
	1,420	2,385

◆

PROGRAMME OF THE FIFTH ANNUAL MEETING OF THE CANADIAN GAS ASSOCIATION.

The fifth annual meeting for the transaction of business, reading of reports, etc., will be held as follows in the Engineers' Club, 94 King Street West, Toronto:—

Tuesday, September 3rd, 9 a.m.—Register at Engineers' Club; Business Meeting; Executive Committee's and Secretary-treasurer's reports; President's Address (Mr. Arthur Hewitt, Toronto); Nomination Committee's report.

Paper by Mr. Howard E. Mann, engineer Montreal Light, Heat and Power Company, Montreal, "Reconstruction of an Old Retort House."

Paper by Mr. H. E. G. Watson, Commercial Department, Consumers' Gas Company, Toronto, "Suggestions for Increasing the Industrial Use of Gas."

12.00 noon - Luncheon.

1 p.m.—The following papers by

Mr. J. J. Armstrong, accountant, Consumers' Gas Company, Toronto, "Consumers' Accounting and Records System."

Mr. C. H. Osler, superintendent of distribution, Montreal Light, Heat and Power Company, "Medium High Pressure Gas Distribution in Montreal."

Mr. C. W. Allman, Commercial Department, Consumers' Gas Company, Toronto, "Gas vs. Coal for Water-heating Appliances."

Mr. W. J. Fuller, Commercial Department, Consumers' Gas Company, Toronto, "Commercial Lighting in Toronto."

Wednesday, September 4th, 10 a.m.—Business meeting at Engineers' Club, announcements, etc.

10.30 a.m.—Sight-seeing trip around the city and a visit to the Canadian National Exhibition.

◆

PERSONAL.

MR. F. G. CLARK, of New York, has accepted a position as chief engineer of the Toronto Electric Light Company.

MR. S. P. PORTER has been appointed executive agent for the Grand Trunk Pacific Railway, with headquarters in Regina, Sask.

MR. GEO. OKXVIK, until recently with the Canadian Bridge Company, of Walkerville, Ont., is now with the city of Toronto in the Department of Railways and Bridges.

PROFESSOR C. C. SLICHTER, Ph.D., of Madison, Wis., U.S.A., has received a commission from the civic authorities of Winnipeg to make a full report on the water supply of that city.

MR. H. E. M. KENSIT, who during the past four years has been occupied in investigating and reporting on various undertakings and projects in Canada and the United States for Messrs. Smith, Kerry and Chace, of Toronto, has received an appointment with the water power branch of the Department of the Interior, Ottawa.

MR. LEROY A. KLING, who has been connected for some time past with two well-known crusher companies in Cedar Rapids, Iowa, has just accepted a position with the Wheeling Mold and Foundry Company, of Wheeling, W. Va., as sales manager of the road machinery department. This is the concern that has built so much of the important machinery for the Panama Canal. They will eventually manufacture a complete line of road building machinery, including a modern crusher, adjustable to crush to any size, pulverizers, rolls, screens, elevators, trucks and graders. Mr. Kling announces that his connection with these people begins at once.

MR. L. J. STREET, vice-president of the Canadian Inspection and Testing Laboratories, and district manager in Toronto for the past eight years, is severing his connection with that firm to go with the Dominion Iron and Steel Co., Sydney, C.B., as assistant to Mr. J. P. McNaughton, general sales manager. For several years Mr. Street was treasurer of the Engineers' Club of Toronto, and on its reorganization a year and a half ago, was elected chairman of its house committee. During his eight years' residence in Toronto Mr. Street has made many friends among the engineers and architects, and by his close application to work and expert attention to large inspection orders handled by him, has done much towards bringing the Canadian Inspection and Testing Laboratories to the high position it occupies in Canada at the present day. Mr. Street's knowledge of the iron and steel requirements of this country should make him a valuable addition to the staff of the Dominion Iron and Steel Co.

MR. JAMES MILNE, recently appointed mechanical and electrical engineer in the Works Department, city of Toronto, has entered upon his duties.

MR. E. M. PROCTOR, who has been with the Canada Foundry for the past two years, has accepted a position in the Department of Railways and Bridges for the city of Toronto. Mr. Proctor is a graduate of the class of '08 in civil engineering of the University of Toronto.

COMING MEETINGS.

CANADIAN GAS ASSOCIATION.—Fifth annual convention will be held in Toronto, August 24th to Sept 9th, 1912, during the Exhibition. Sec'y-Treasurer, John Keillor, Hamilton, Ont.

THE UNION OF CANADIAN MUNICIPALITIES.—August 27, 28 and 29. Meeting at City Hall, Windsor, Ont. Hon. Secretary-Treasurer, W. D. Lighthall, K.C.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Opening Meeting, Washington, D.C., September 4th, 1912. Other meetings, Business and Scientific, in New York, beginning Friday, September 6th, 1912 and ending September 13th, 1912. Secretary, Bernhard G. Hesse, Ph. D., 25 Broad Street, New York City.

INTERNATIONAL ASSOCIATION FOR TESTING MATERIALS.—Sixth Congress will be held in the Engineering Societies Building, 29 West Thirty-ninth Street, New York, Sept. 2-7, 1912 Secretary, H. F. J. Porter, 29 West Thirty-ninth Street, New York.

ILLUMINATING ENGINEERING SOCIETY.—Sixth Annual Convention to be held at Hotel Clifton, Niagara Falls, Ont., Sept. 16-19, 1912. Secretary, Preston S. Millar, 29 West Thirty-ninth Street, New York.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. The Secretary, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill: Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H Victor Brayley, N T Ry, Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving: Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh [illegible] 409 Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill [illegible].

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible]

WINNIPEG BRANCH—[illegible] Brydone [illegible] and third Friday of each month, October to April, in [illegible]

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President, J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto. Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer [illegible], Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. [illegible] Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, [illegible]

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, [illegible]; Secretary, H. [illegible] Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan [illegible]; Permanent Secretary, Norman S. Rankin, P.O. [illegible]

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, [illegible] Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
8-31	Trenching and Backfilling, Edmonton, Alta. (S.)	8-8

(Canora specifications are also on file at the office of The Canadian Engineer, Rooms 617-628, Transportation Building, Montreal.)

TENDERS.

Craik, Sask.—Tenders will be received by Chas. R. Hainsworth, secretary-treasurer, town of Craik, Sask., until noon of September 9th, 1912, for the following buildings to be erected in Craik:—

(1) Town Hall (alternative tenders as per specifications).
(2) Skating and curling rink.

Plans and specifications may be seen at the offices of Messrs. Storey and Van Egmond, architects, Regina or Saskatoon, and at the office of the secretary-treasurer of the Town of Craik.

Creelman, Sask.—Tenders for building a two-roomed school building of solid brick with a concrete basement in the village of Creelman, Sask., according to plans and specifications which may be seen at the office of Geo. J. C. Jarrett, architect, Weyburn, Sask., or S. R. Carrothers, sec.-treas., Creelman, will be received until August 31st, 1912, at the office of the secretary-treasurer, S.D. 998, Creelman.

Dewdrop, Sask.—Tenders will be received at the office of Alex. Tibeau, secretary, Dewdrop, until Sept. 21, 1912, for the purpose of building a schoolhouse and barn. Plans may be obtained at the secretary's office.

Dunnville, Ont.—Tenders for the construction of a concrete pavement, together with curb and channel on Chestnut, Canal East and West, and Lock Streets, will be received until August 31st, 1912, at the office of Alan Mair Jackson, town engineer, at whose office plans and specifications may be seen. (See advt. in Canadian Engineer.)

Montreal, Que.—Tenders addressed to the Board of Commissioners, City Hall, will be received until noon of August 30th, 1912, for the construction of asphalt, block or asphaltic composition pavements, on eleven streets, full particulars of which may be obtained at the office of the Engineer, Superintendent of the Road Department. L. N. Senecal, secretary, Board of Commissioners, City Hall, Montreal.

Montreal, Que.—Sealed tenders for the supply and delivery of three city fire trucks, and one 800 U.S. gallon steam fire engine, addressed to the Board of Commissioners, City Hall, will be received until noon of September 5th, 1912. Specifications, etc., may be obtained from the Purchasing and Sales Agent, City Hall. L. N. Senecal, Secretary, Board of Commissioners' Office, City Hall, Montreal.

Ottawa, Ont.—The time for receiving tenders for the construction of the Victoria Harbour, B.C., Breakwater, is extended to Wednesday, September 18th, 1912. R. C. Desrochers, Secretary, Department of Public Works, Ottawa. (See advertisement in The Canadian Engineer).

Ottawa, Ont.—Tenders addressed to A. W. Campbell, Chairman Government Railways, Managing Board, Ottawa, will be received until September 12th, 1912, for the construction of an addition to the freight car repair shop at Moncton, N.B. Plans and specifications may be seen at the office of the Secretary of the Department of Railways and Canals, Ottawa, and at the Chief Engineer's Office, Moncton, N.B.

Ottawa, Ont.—The Department of Public Works, Ottawa, will receive tenders until September 12th, 1912, for the construction of an extension to the breakwater at North Head, Grand Manan, Charlotte County, N.B. Plans, etc., can be obtained at the Department, and at the offices of F. G. Goodspeed, Esq., District Engineer, St. John, N.B.; Geoffrey Stead, Esq., District Engineer, Chatham, N.B., and on application to the Postmaster at North Head, N.B.

Ottawa, Ont.—The Toronto General Trusts Corporation, 30 Elgin Street, Ottawa, will receive tenders up to the 20th day of December next for the purchase of several valuable timber limits. Maps, etc., may be seen at the offices of the above and at the offices of Messrs. Aylen & Duclos, barristers, Castle Building, Ottawa, or Messrs. Belcourt and Ritchie, barristers, Castle Building, Ottawa.

Ottawa, Ont.—Tenders will be received by R. C. Desrochers, Secretary, Department of Public Works, Ottawa, until September 12th, 1912, for the supply of lumber and timber, etc., for one 3½ cubic yard dipper dredge, and for the supply of white oak, British Columbia fir and white pine, for four 95 cubic yard hopper scows. Specifications, etc., can be obtained at the offices of T. H. Schwitzer, Esq., Mechanical Superintendent, Birks Building, Ottawa, Ont.; J. G. Sing, Esq., District Engineer, Toronto, Ont.; J. L. Michaud, Esq., District Engineer, Merchants Bank Building, Montreal, Que., and at the office of the Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders addressed to P. E. Ryan, secretary, office of the Commissioners of the Transcontinental Railway, Ottawa, will be received until Sept. 10th, 1912, for furnishing and installing all piping systems, pipe tunnels, pipe coverings, and wiring ducts required in connection with the car shop plant of the Winnipeg shops, about six miles east of Winnipeg, Man. Plans, etc., at the office of Mr. W. J. Press, mechanical engineer, Ottawa, and at the office of Mr. H. H. Pinch, asst. engineer, Transcona, Man. (See advt. in Canadian Engineer.)

Ottawa, Ont.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, for the construction of a retaining wall in the town of Owen Sound, Ont., will be received until Sept. 28, 1912. Plans, etc., at this department and at the offices of J. G. Sing, Esq., district engineer, Confederation Life Building, Toronto; H. J. Lamb, Esq., district engineer, Windsor, Ont.; and on application to the Postmaster at Owen Sound, Ont.

Ottawa, Ont.—Tenders for the purchasing of the plant owned by the Department at the Timiskaming Dam, Timiskaming, County of Pontiac, P.Q., will be received until September 19, 1912. The list of plans and forms of tender can be seen and obtained at the Department of Public Works, Ottawa, and at the offices of C. R. Coutlee, Esq., Engineer in charge, Corry Building, Ottawa, Ont., and of H. H. Donnelly, Esq., Resident Engineer, Timiskaming, P.Q. R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—R. C. Desrochers, Secretary, Department of Public Works, Ottawa, will receive tenders until September 11, 1912, for the erection of a residence for the Medical Superintendent of Lazaretto, Tracadie, N.B. Plans, etc., at this Department, and at the offices of Mr. D. H. Waterbury, Superintendent of Public Buildings, Public Works Department, St. John, N.B., and Dr. J. A. Langis, Medical Superintendent, Tracadie, N.B.

Ottawa, Ont.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until Sept. 17, 1912, for the construction of a wharf with stone approach at the village of Bell Ewart, county of Simcoe, Ont. Plans, etc., at the office of the secretary, and at the offices of J. G. Sing, Esq., district engineer, Confederation Life Building, Toronto, Ont.; H. J. Lamb, Esq., district engineer, Windsor, Ont.; and on application to the [illegible]

Ottawa, Ont.—Sealed tenders addressed to R. C. Desrochers, secretary, Department of Public Works, for the construction of a wharf [illegible] at Big Bay Point, in the township of Innisfail, county of Simcoe, Ont., will be [illegible]

Regina, Sask.—[illegible]

Toronto, Ont.—[illegible]

Victoria, B.C.—Plans for the two garbage stations at Spring Ridge and Fairfield are ready and tenders will be invited at an early date.

Victoria, B.C.—Tenders for the erection and completion of an industrial school for girls, will be received by the Hon. the Minister of Public Works, Victoria, until noon of September 9th, 1912. Plans, etc., may be seen at the offices of the Government Agents, Vancouver and New Westminster, and the Department of Public Works, Victoria. J. E. Griffith, Public Works Engineer.

Victoria, B.C.—Tenders for the erection of a schoolhouse at Quesnel will be received up to noon of Wednesday, September 4th.

Winnipeg, Man.—Tenders for the erection and completion of a twelve-room brick school building at Transcona, Man., will be received until Sept. 9, at the office of E. D. Tuttle, architect, 701 McArthur Bldg., Winnipeg.

◆

CONTRACTS AWARDED.

Belleville, Ont.—Messrs. Thomas Manley and Sons, contractors, have begun a $40,000 contract of building culverts for the Canadian Pacific Railway in Sidney Township, west of this city.

Camrose, Alta.—At a meeting of the council a resolution was passed accepting the tender made last year by the Western Paves, Limited, for the laying of cement sidewalks on the first two blocks of Main Street.

Galt, Ont.—Messrs. Thomas and Hancock have been awarded the contract for the concrete and brick work of the addition to be built to the Galt Robe Works.

Moose Jaw, Sask.—The contract has been awarded by the Moose Jaw Hardware Company for the erection of a $30,000 warehouse on the corner off Fairford Street and Seventh Avenue.

Moose Jaw, Sask.—The contract for the erection of the new Young Women's Christian Association has been awarded to the Western Improvement Company, Minot, North Dakota. The contract price is $56,383, which does not include lighting, heating or plumbing; these will be awarded later. L. T. Stromswold is president of this contracting firm.

North Toronto, Ont.—Mr. M. J. K. Allen, who was recently awarded certain paving contracts has been released from the obligation. The council then reconsidered other tenders with the result that Mr. E. G. Law was awarded the contract for Tarvia paving at a price of $1.58 per square yard and 40c. per lineal foot for curbing. This is an increas of $5,950 over Mr. Allen's offer.

Port Colborne, Ont.—A despatch from Montreal states that contracts have been let by the Montreal Transportation Company, by which the Canadian canal trade will have the first electrically-propelled merchant vessel ever built. The ship is being built by the Messrs. Swan, Hunter & Wigham Richardson firm.

Saskatoon, Sask.—Mr. G. N. Hughes is the contractor for the new apartment block to be erected by W. W. McKim at the corner of 23rd Street and 5th Avenue at a cost of $40,000.

Swan River, Man.—Messrs. J. W. Gunn and Sons, Winnipeg, are the contractors for building the concrete piers for the new $20,000 steel bridge which the Canadian Northern Railway is building over the Swan River.

Sydney, Cape Breton, N.S.—The contracts for the new [illegible] and McCurdy buildings have been awarded to Rhodes, Curry and Co. and Chappell Bros.

Toronto, Ont.—The contract for the erection and completion of a new bath house on St. David Street has been awarded to John [illegible], his price being $[illegible].

Toronto, Ont.—The Board of Control have made the awards for the work of supplying pipe for a 36" water main. The National Iron Works' tender of $[illegible] a length for [illegible] lengths, and the tender of the Canada Iron and Foundry Company for [illegible] lengths at $[illegible] per length, were accepted.

Barrett Specification Roofs

The Place to Break the Pen!

The building shall be covered with a Barrett Specification Roof or

IN writing your roofing specifications it is especially important not to add "or equal thereto."

You need precision in dealing with a roof more than with any other part of the structure for the reason that in laying a roof there are many opportunities for "skinning the job."

Further, you put the honest, reliable contractor at a great disadvantage when you ask him to bid on an indefinite or vague specification, and such specifications usually mean poor workmanship and cheap materials with subsequent leaks and trouble.

There are various ways of constructing gravel and slag roofs, but if The Barrett Specification is followed, there is no chance for mistakes or slipshod workmanship.

It describes in a practical way how to use Specification Felt and Specification Pitch to make a first-class roof—one that will always give maximum service.

The Barrett Specification embodies the best experience of the roofing industry and is designed for the benefit of architects, engineers and owners.

Incorporate it in full into your own building specification and you will be ordering a roof that has shown a lower cost per foot per year of service than any other type of roofing ever made.

We know that if all buildings were covered with Barrett Specification Roofs, roof troubles would be practically nil.

Copy of the Barrett Specification ready for incorporation into building specifications free on request.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If an abbreviated form is desired, however, the following is suggested:

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified, and subject to the inspection requirement.

THE PATERSON MANUFACTURING CO., LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

Vancouver, B.C.—The contract for the erection of the substructures of eight steel bridges and trestles on the Canadian Northern Pacific Railway east of Yale, has been awarded to Messrs. Rigby & Marsden, of Vancouver. The total amount of money involved in the work is about $60,000, and the total of the eight completed bridges will be $300,000.

Vancouver, B.C.—Mr. Ambrose Adams has been awarded the contract to construct a six-story warehouse for Messrs. Stewart and Crombie at a cost of $61,000.

Vancouver, B.C.—Messrs. Phelan & Shirley, Palmer Brothers & Henning, of Vancouver; and J. Hogan, of Edmonton, have been awarded a contract for the construction of 60 miles (20 miles each) of track on the Northern Railway from Yellow Head Summit west and southward.

Victoria, B.C.—The contract for the construction of the big dam at Jordan River, for the B.C. Electric Railway Company, has been awarded to the Puget Sound Bridge and Dredging Company, of Seattle. The dam will be 800 feet long and 115 feet deep, and will be modelled after the Ambursen type of reinforced concrete structure.

Winnipeg, Man.—The contract for the supply of a quantity of water meters has been awarded to the National Meter Company, of Chicago, for $61,878.75.

Winnipeg, Man.—Tenders for the supply of materials for the extension of the fire service waterworks have been awarded as follows:—High pressure water pipe and specials, Canada Iron Corporation, Montreal, $64,211.71; valves, Rensselaer Valve Company, Troy, N.Y., $3,537.50; hydrants, Florence Iron Works, Philadelphia, Pa., $11,484.

◆

RAILWAYS—STEAM AND ELECTRIC.

Edmonton, Alta.—The commissioners have decided to purchase new fare boxes for the street railway cars. Mr. Woodroffe, superintendent of street railway.

Galt, Ont.—A report states that a portion of the lines of the Grand Valley Railway will soon be operating under the pressure of the hydro-electric system. The Galt, Preston and Hespeler Railway is operated from this source at present.

◆

LIGHT, HEAT AND POWER

Berlin, Ont.—The management of the Canadian Consolidated Rubber Company have made a request for an estimate [illegible] h.p. from the Berlin Light Commission. If the [illegible] to that now consumed in this municipal[illegible] the rates will be reduced.

Beauharnois, P.Q.—A group of Montreal financiers and business men have formed a company with the idea of erecting a power plant at this point. They have received the approval of the provincial government and will have powers in the city of Montreal, in the counties of Laval, Jacques Cartier, Hochelaga, Laprairie, Chateauguay, Beauharnois, Two Mountains, Argenteuil, Soulanges, Vandreuil, Terrebonne, L'Assomption, [illegible], Huntingdon, Napierville, St. Jean and Iberville.

Kingston, Ont.—The municipal council has decided to [illegible] the sum of $[illegible] for the enlargement of the present steam plant used for city light and power. Mr. P. Kelch, Montreal, P.Q., consulting engineer to the municipal council.

Nelson, B.C.—[illegible]

Port Dalhousie, Ont.—The ratepayers voted in favor of the installation of a hydro-electric lighting and power system for this municipality. Mr. [illegible] is Reeve of the place.

Victoria, B.C.—The Canadian Pacific Railway [illegible] that the provincial government and certain land owners will [illegible] of the municipal council, is [illegible] in the matter.

GARBAGE, SEWAGE AND WATER.

Calgary, Alta.—The ratepayers by a small vote defeated the proposed expenditure of $405,000 to construct a filtration plant and a new intake pipe.

Calgary, Alta.—City Engineer Childs is preparing plans and estimates for a sewage disposal plant to be erected in Ogden. This work will cost about $20,000.

East Toronto, Ont.—Sewers for the former town of East Toronto, at a cost of $327,500, are recommended by Works Commissioner Harris.

Guelph, Ont.—The municipal engineering department have reported that the Huskisson Street drain must be diverted. M. Ferguson, city engineer.

Kingston, Ont.—The Board of Health of this municipality has taken a definite action to secure the consent of the Civic Utilities Commission in the matter of supplying the filtration plant endorsed some time ago. R. J. McClelland, city engineer.

Kindersley, Sask.—Contracts have been let for the construction of a $90,000 waterworks system and electric light plant in this town.

Ottawa, Ont.—It is reported that Prof. Starkey, of McGill University, will be appointed as the representative of the Canadian section of the internal waterways commission to enquire into the question of the pollution of boundary waters.

Toronto, Ont.—The sum of $15,000 has been voted by the Board of Control to make a preliminary examination of the lake bed at Scarboro Bluffs in connection with the proposed duplicate waterworks system at that point. The New York firm of Smith and Travis will be engaged. Borings at the lake bed will be made, first along the shore, and then as far out as two miles, with 600-foot centres. The services of Prof. A. P. Coleman of the faculty of applied science of the University of Toronto will be secured by the city as adviser.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Calgary, Alta.—R. B. Bennett, K.C., has recently returned from a business trip to England, and made the announcement that he is interested in a large industrial undertaking that will mean much to Alberta and Calgary when the details are in such a condition as to be made public.

Calgary, Alta.—Pending the selection of a site the federal government are ready to construct an armoury in this city.

Edson, Alta.—Mr. M. Greenberg has started construction work on a 45-roomed hotel that will cost $40,000 before completion. It will be heated by steam and contain other modern appliances.

Fredericton, N.B.—Many important changes have been made in the plans of the new fire hall for this city. Tenders will be called in the course of a few days. Ald. Cruikshank is chairman of the committee dealing with this matter.

Galt, Ont.—Messrs. W. D. Sheldon, J. F. MacGregor and Allen Hills, all of this town, are interested in a new project of the Hare Engineering Company. $400,000 of capital stock in this company has been taken up in Great Britain and the company will now erect a plant to manufacture power equipment and pulp machinery. The plant to be erected in this town will cost about $150,000.

Kingston, Ont.—The management of the Canadian Locomotive Company are about to erect several residences for the mechanics employed by them. Fifteen double houses are to be built before the winter months.

Moose Jaw, Sask.—The Moose Jaw Steam Laundry have taken out a permit for the erection of an addition to their plant. There will be considerable machinery necessary for the work to be conducted in the new wing. The cost of the building will be about $10,000.

Montreal, P.Q.—A large glass factory will be erected in Montreal West near the Canadian Pacific Railway's new yards. There will be about 600 men employed when this industry commences operations.

Northern Ontario.—It is the intention of the department of public works of the Dominion Government to begin shortly preparation of plans and estimates for the improvement of the French River, for which work $100,000 was appropriated at the last session of parliament. The river is the connecting link between Georgian Bay and Lake Nipissing, and as such is a part of the projected Georgian Bay canal.

Pelee Island, Ont.—Mr. H. Henderson, of this island, is at the head of a company which will build a passenger and freight steamer to run between this place and the main land. The cost of this work will be about $60,000.

Prince Rupert, B.C.—Plans are now being prepared in the department of public works, Victoria, for the new provincial buildings to be erected at Prince Rupert.

St. John, N.B.—The Grand Falls Power Company will establish at Grand Falls on the St. John River, a pulp and paper making plant at a cost of between $5,000,000 and $7,000,000. Eminent hydraulic engineers from the United States are now at work revising the plans for developing the power and erecting the plant.

St. Mary's, Ont.—The management of the St. Mary's Wood Specialty Company are making preparations for extension of their plant. They have taken an option on a flax mill and if the shareholders so decide, they will install such machinery and make such changes as may be necessary.

Toronto, Ont.—Mr. James O'Neill, proprietor of the St. Charles Hotel, is interested in a project calling for the erection of a 600-roomed hotel.

Toronto, Ont.—The management of the Northern Aluminium Company, local offices 1106 Traders Bank Building, Toronto, will erect a factory for the manufacture of their specialties on Sterling Road.

Toronto, Ont.—The municipal property commission have endorsed two sites selected for the erection of public lavatories at a cost of $8,000 each.

Vancouver, B.C.—The ratepayers will be asked to vote on the question of the erection of a proposed new school building on Pender Street East. The estimated cost of this work is $15,000.

Watrous, Sask.—The municipal council has closed an agreement with the Perfection Fanning Mill Company whereby the latter will erect a factory and start manufacturing their products in this town at an early date.

Welland, Ont.—An amalgamation of the Lake Shore Seed Company and the Dunkirk Seed Company, has been formed and will erect a brick factory, two-story, 450 x 100 feet, to be used for putting vegetable seeds into packets. Mr. J. H. F. Kaufman, of the Lake Shore Seed Company, has looked after [illegible] the Welland interests.

BRIDGES, ROADS AND PAVEMENTS.

Guelph, Ont.—Mr. M. Ferguson, city engineer, will prepare plans for a new bridge that the council have decided to erect over the River Speed in the place of the present Victoria Bridge.

Toronto, Ont.—The municipal Board of Control has recommended that the proposed Bloor Street Viaduct be made [illegible] as the present design calls for.

FIRES.

Western Lower Ontario.—Considerable damage was [illegible] and other [illegible]

CURRENT NEWS.

Eastern Canada.—[illegible]

Moose Jaw, Sask.—The Municipal Hospital Board held a meeting to consider a report prepared by Mr. Meyer J. Sperm, of Chicago, who has made an investigation of the conditions in Moose Jaw. He recommended that a building costing $300,000 be considered and erected on the unit basis.

New Westminster, B.C.—There is much dissatisfaction regarding the operation of the telephone system in this city and a movement has been started among the business men to petition the council with a view of granting a franchise to another company.

Niagara Falls, Ont.—It is reported that the large touring car, driven into the forebay of the Ontario Power Company, to extinguish a fire that had broken out while travelling along the river bank, has been washed over the falls. Divers have been at work for some time and nothing has been found excepting a door of the machine at the Maid of the Mist landing stage.

Ottawa, Ont.—The City Solicitor has engaged the services of two inspectors to crawl through the concrete aqueduct for the purpose of making a report on the condition of the concrete. This pipe has an internal diameter three feet six inches and is sixteen hundred feet in length.

Province of Manitoba.—In future all telephone extensions will be carried out by contract instead of day labor. It is expected that this will entail a saving of $80,000 per year to the Manitoba Government.

Regina, Sask.—The members of the Loyal Order of the Moose lodge of Regina recently issued a number of small celluloid bricks on which was printed "This entitles bearer to 25 cents worth of hospitality at the Moose Temple, Regina, Sask.," and from the sale of the same raised the sum of $15,000 toward the expense of erecting the new lodge rooms in this city.

Quebec, P.Q.—There is a large building boom coming across this city; ten permits were issued last week, which is the largest number in one week for many seasons.

Toronto, Ont.—The committee dealing with the proposed new technical school for this city have decided to ask for alternative tenders for brick and stone walls. If this is adopted the cost will be about 25% more than the present estimate. Messrs. Ross and McFarlane are the architects.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending August 8th, 1912:

A pottery firm in the Midlands desires to be put in touch with a Toronto firm wishing to represent English manufacturers of pottery, etc.

Inquiry is made on behalf of a Canadian firm of automobile and motor wagon manufacturers for the names of English manufacturers of auto parts and chassis willing to cooperate with them.

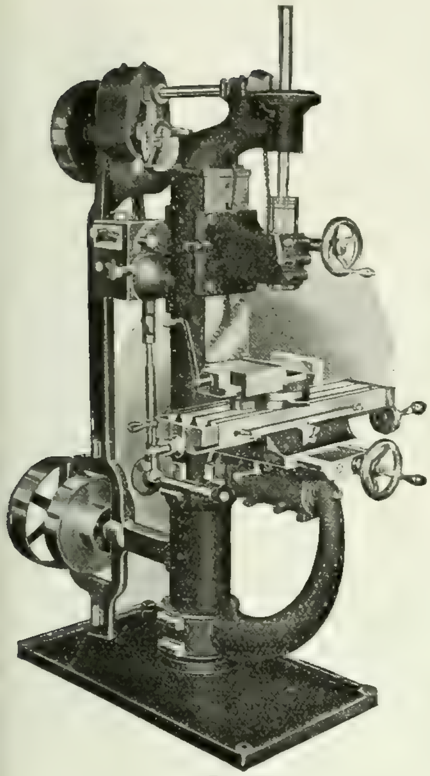
From the branch for city trade inquiries, 73 Basinghall Street, E.C.:

A Liverpool firm manufacturing a patented press for baling flax wish to arrange for their sale in Canada.

A London company manufacturing various kinds of soaps, toilet specialties and disinfectants, are looking for suitable Canadian resident agents, but require persons who have an expert knowledge of this trade and an established connection among buyers.

NITRATE MANUFACTURE IN SPAIN AND CANADA.

It is stated on apparently reliable authority that a Spanish consortium of financiers has recently inspected the nitrate works at Notodden with a view to the possibility of establishing a factory in Barcelona. It is proposed to transfer the Norwegian [illegible] method to a Spanish and a Canadian company. In the event of the latter proposition materializing, the works would be in the neighborhood of Montreal. It will be stipulated that the managers shall be Norwegians.



You Need a Machine Like This on a Dozen Different Jobs

It's a No. 2 Knight Milling and Drilling Machine

This machine is very rigid, powerful and accurate, so that close work may be turned out with a high degree of satisfaction, and in the shortest possible time. The adjustments are quickly and easily made. On a large variety of work it is possible to make a saving of from 20 to 50 per cent. in time, as compared with other machines.

The fact that hundreds of Knight Machines are now in use in this and foreign countries proves that they are not experiments.

These machines are made in three sizes.

Briefly, the construction of the No. 2 Knight Miller is as follows :—Spindle of crucible steel, ground bearings ; working surface of table, 29 × 8½ inches ; feed, longitudinal and transverse ; floor space, 60 × 68 inches ; weight, crated for shipment, about 2,500 lbs.

MANITOBA'S FIRE LOSSES

"The fire losses on this continent from January 1, 1911, to July 1, 1912, are almost $135,000,000, which means that if, in the next six months, the same record is kept up, the fire losses for 1912 will show that the people have again recklessly destroyed $270,000,000 of property in the United States and Canada." Mr. Lindback, Manitoba's Fire Commissioner, makes this statement.

"Of these $135,000,000 losses," he adds, "in the first six months of the year Canada must be charged with about $15[illegible], of which Manitoba's share is one million, equal to a tax of $4 on every man, woman and child in the province—while in England the same tax is not over 40 cents per capita.

"While the United States escape with a per capita loss of $2.50, Canadians are taxing themselves $3.50 per capita, at the rate we have been burning created values during these six months. After an analysis of the causes, it will be plain how utterly indifferent we are in regard to fire prevention.

"On January 3rd the Excelsior Garage burned with a loss of some $115,000, caused through ignorance and carelessness. On the 22nd of the same month a cold storage, with a loss of $315,000, took fire at noon through carelessness.

"On March 9th a sash and door warehouse was destroyed, with a loss of seven lives and $24,000, first, because of non-conformity to the city by-law, second, because of non-inspection by the proper city authorities, and, finally, because the two or three barrels of gasoline used in the warehouse per week were handled under the name of naphtha, and therefore not considered dangerous. On March 5 a fire started in a building on Main Street while the people were still in the office; loss, $20,000; cause, carelessness with a lighted match.

"On April 23rd the Brown-Rutherford plant was destroyed by a spark from their smoke-stack falling in the sash and door warehouse during a very heavy wind, the fire getting beyond the fire department for want of sufficient water at the beginning of the blaze. Loss, $250,000.

"On May 3rd fire started on the platform of a warehouse located on the Canadian Pacific Railway track by a spark from an engine falling in some rubbish on the platform, notwithstanding the parties had been frequently warned about removing such rubbish. Loss from this fire was $34,000. To prove how little effect a lesson of this kind has, on June 20th another fire started under exactly similar conditions in what was left, but with less loss, because there was not so much to burn.

"On May 30th fire started in an unfurnished house on Home Street, causing a loss of $20,000. At the time I suggested the need of a watchman in such buildings under construction, but with no results. Loss here about $50,000.

"The province at large presents a similar record of indifference to fire prevention, although naturally a smaller money loss. But the fact to be deducted from the fire record is that while Canada and the continent generally have realized the need of prompt and drastic action where epidemics and diseases are in evidence, we are far behind in the work of fire prevention."

◆

NOTES ON MINERAL WASTE.

In the preface to Bulletin [illegible] "Notes on Mineral Waste," [illegible] of the Bureau of Mines, [illegible] Dr. Joseph A. Holmes, the director, [illegible]

Dr. Holmes says: [illegible] for the purpose of lessening the waste of essential resources—investigations on the same general lines as those looking to a reduction in the loss of life in the mining operations of the country and the far more extensive investigations looking to the more efficient production and use of agricultural products, both of which are being conducted by the Federal Government.

"In consideration of the possible activities of the individual, the State, and the Federal Government in behalf of a less wasteful use of our mineral resources certain facts and principles should be kept clearly in mind, namely:

"That the present generation has the power, and it will exercise the right, to use as much of the country's resources as it actually needs; there can and there will be no such thing as stinting the present generation by bottling up resources for the use of the future.

"That the nation's needs are not likely to be curtailed; these needs will increase with the extent and diversity of the nation's industries, and they will increase more rapidly than population increases, for the reason that the per capita consumption of mineral products is rapidly increasing; and

"That the men of this generation will not mine, extract or use these resources at continuous financial loss to themselves in order that something may be left for use of future generations; there can be no such thing as a mineral industry without profits.

"Furthermore, it should be clearly understood that the mineral resources of this country have required long ages for their accumulation and that of these resources the nation has but the one supply. There are no known substitutes available to meet the nation's further needs when that supply will be exhausted and, to the best of our present knowledge, this one supply must serve as a basis for both the needs of the present and the far greater needs of the future.

"In a higher way our mineral resources should be regarded as property to be used and to be held in trust with regard to both the present and the future needs of the country. It should be remembered that neither human labor nor any human agency has contributed to their origin or to their intrinsic value, and that whatever rights the individual may possess have been derived from the general Government and from the State as the original owner. The State does not surrender its right, and should not neglect its duty, to safeguard the welfare of its future citizens by preventing the wasteful use of these resources. Though the individual may claim the right to use the resources in proportion to his needs and the needs of the community, he certainly has no right to waste that which is not needed for present use but is certain to be needed hereafter.

"Those in charge of the investigations of the Bureau of Mines recognize the rights and duties of the Federal Government as being limited to the carrying on of inquiries and investigations with a view to determining the nature and extent of this waste of resources, the means by which it may be diminished, and the setting forth of the facts in the case.

"The present report embodies the results of certain preliminary inquiries as to the nature and extent of this waste. It will be followed by a more detailed report on the subject as soon as the necessary inquiries and investigations have been conducted and the results put in shape for publication.

"In the preliminary work along these lines, the representatives of the bureau have received the cordial co-operation of the engineers and chemists associated with the varied mineral industries of this country and also of the owners and the operators of the mines and the metallurgical plants."

Copies of this bulletin may be had by addressing the director of the Bureau of Mines, Washington, D.C.

ANOTHER TRANSCONTINENTAL.

A new transcontinental line, with Fort Churchill on the east and Port [illegible] on the west as terminals, connecting Edmonton with Lac la Biche, Fort McMurray and Lake Athabasca, is projected. It is to be called the Northern Territorial Railway, and it is reported that it will commence a survey of its route from Edmonton northeasterly in the course of the next few days. The corporation has authorized capital of $[illegible] and under the charter which was granted by the Dominion Parliament at its last session has bonding power amounting to $[illegible] per mile. The length of the transcontinental from the coast will be 1,450 miles.

The Canadian Engineer
An Engineering Weekly

SOME NOTES ON THE OAKVILLE VIADUCT AND THE DYNAMITING OF THE CONDEMNED ARCH RIBS, AUGUST 12, 1912.

By C. H. CUNNINGHAM, B.A.Sc.

On Tuesday, August 13th, a rather interesting, and certainly unusual, event took place in Oakville when the big arch ribs forming the main span of the concrete viaduct under course of erection there, were dynamited. The arch span consisted of two ribs side by side, with vertical concrete posts carrying the slab and girders of the floor system.

These ribs had been completely concreted, but owing to several very serious faults in the construction, it was deemed advisable to destroy them and rebuild.

It was during the summer of 1911 that the county of Halton decided to call for tenders on a reinforced concrete viaduct over the 16-mile creek on the middle road between Oakville and the township of Trafalgar. Competitive designs in steel and reinforced concrete had already been prepared, calling for a clear roadway of eighteen feet. It was decided to adopt the concrete design and reduce the clear roadway to sixteen feet. Accordingly, these plans were prepared by Frank Barber, C.E., Toronto, as consulting engineer for Halton county, and on August 23rd the contract was awarded. Two schemes were submitted, one of which called for the floor to be 40 feet above ordinary water level, and the other at 50 feet. Owing to the better grades obtainable on the approaches the latter plan was the one adopted.

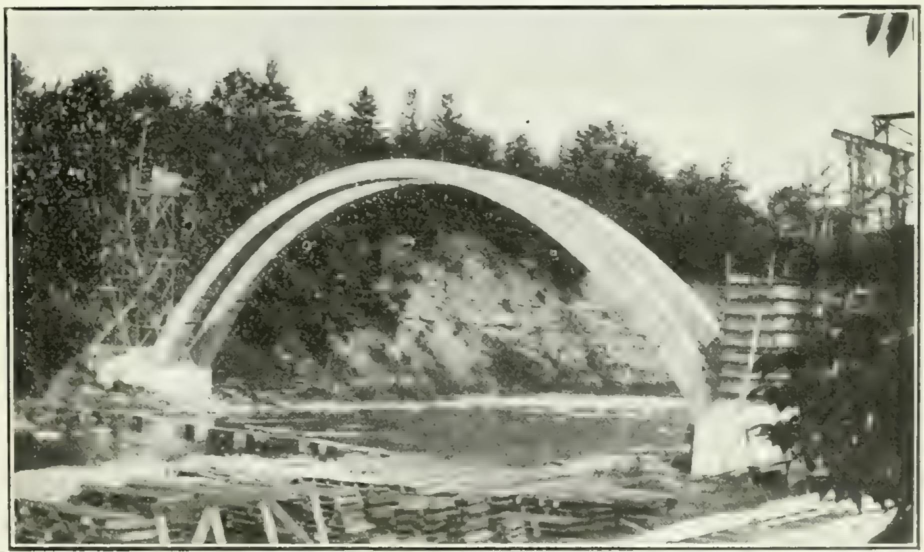

Fig. 1.—Showing the Arch Just Before the Blasts.
The notches where the rods were cut are plainly visible.

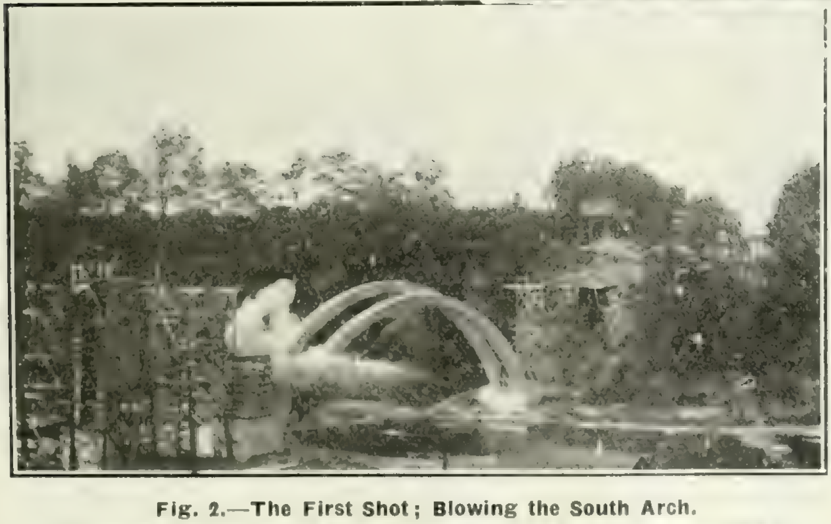

Fig. 2.—The First Shot; Blowing the South Arch.
The charge in the east haunch did not explode, leaving a long end as seen in Fig. 3.

The main features of the design are a cantilevered slab floor supported on two main girders of various spans at 9 feet centres, which frame into square posts supported on heavy concrete piers. The stream itself to be spanned by a double rib arch of 135 feet 0 inches clear span on which the floor is carried by vertical posts and small girders. The arch ribs are if uniform width throughout, being 3 feet 3 inches square at the crown and increase in depth to 5 feet 6 inches at the skewbacks. The floor slab has an average thickness of 12 inches, and is reinforced entirely with ¾ inch round rods, cantilevering about four feet on each side.

The girder spans, which form the viaduct approaches on each side of the arch are eight in number, six being on the west side; and range in lengths from 34 feet to 48 feet.

The parapets are also of concrete, and have practically no ornamentation. In fact, the whole structure is noticeably plain. Immediately that the contract was awarded work was begun, in order to get as much done as possible before frost set in. Concreting actually commenced on the footings on October 5th, and by the end of

November the arches were ready to concrete. It was at this point that the regrettable trouble ensued which culminated in the contractor going ahead contrary to the engineer's orders and concreting the arch ribs on centreing which was not sufficiently braced. An injunction and law suit followed, but meanwhile the arch ribs had been finished.

An investigation followed and showed up a considerable number of defects in the arches as erected. Also the weight of concrete was found to have been too great for the centreing, which had shifted and thrown the centre line of the ribs out of a vertical plane to the extent of about three inches at places. Probably no one of the faults in itself would have been sufficient to condemn the arches, but when all were summed up the engineers did not feel that they could stand behind the structure as it then was, and recommended rebuilding them.

An adjustment was finally arranged and the original contract cancelled. Work was not resumed till the spring, when another contractor undertook to complete the job for the county on a cost plus 10 per cent. basis. Work recommenced the end of June, since when good progress has been made.

The council finally decided to blow out the old arches, and accordingly all preparations were made. The concrete [illegible] was chipped away and the rods themselves cut at two places near each end haunch. There was but one connecting strut between the two ribs, situated at the crown. This was also severed and [illegible]

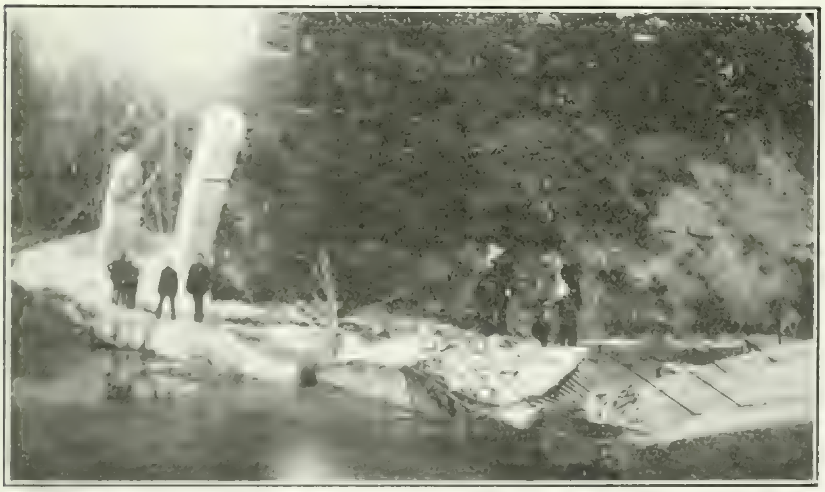

Fig. 3.—The Arches Blown Out and Lying in the Stream.

[illegible] at the break.

Charges were placed in the crowns and near each haunch. Dynamite was used and fired by the electric spark to ensure simultaneous explosions, although any one charge would have sufficed to destroy the arch.

The south rib was dynamited first, after which the [illegible] whatever, and the skewbacks on the main piers were left unharmed. The photographs here reproduced will show [illegible]

[illegible] from dust. Although these rods were simple rounds having [illegible]

From a military standpoint it might be interesting to note the ease with which such a structure as this could be destroyed by dynamite if so desired. One heavy charge, favorably placed, would be sufficient to preclude the passage of a stream that was not in itself readily fordable. However, it should be remembered that it took over a week for two men to cut the rods, in order that there should be as little damage done as possible to the skewbacks and piers.

ALUMINUM AND ELECTRO-METALLURGY IN FRANCE.

From a recent consular report we learn that the French manufacturers have formed themselves into a company called L'Aluminium francais, with a share and debenture capital amounting to 17,000,000 fr. ($3,400,000). The most interesting part of this combination lies in the fact that the new company has acquired the exclusive rights all over the world in the Serpeck process of aluminum manufacture, hitherto vested in the Nitride Company (Société des Nitrures), who had in 1910 bought up the rights and plant (at Mulhausen) of the Swiss holders of the patent, and had established experimental work in the valley of the Arc, near St. Jean de Maurienne. The Serpeck process, by which the production of nitrates forms part of the manufacture of aluminum, consists in the treatment of bauxite, the raw material of aluminum, in the electric furnace with air and coke, so as to fix the nitrogen, thus producing a nitride of aluminum. This product is then treated with a solution of caustic soda, which produces aluminate of soda and ammonia gas. From the aluminate of soda is extracted pure alumina, from which aluminum is obtained by the usual electrical process; while the ammonia gas is treated with sulphuric acid and produces sulphate of ammonia, largely used as artificial manure. The process is thus closely allied with that in use for the production of nitric acid and nitrates by the union of oxygen, nitrogen and steam in the electric furnace, dealt with under the heading of electro-chemical industries. Large works, utilizing 40,000 horse-power, are about to be established by the Aluminum Combine for the purpose of manufacturing under this process. The alumina thus obtained will be used by the various aluminum works grouped together in the new organization, and it is intended to carry on the production of the metal on a larger scale than ever, and to extend its use by all possible means. The company is also said to contemplate the erection of rolling and drawing works near Chambéry. It is calculated that, given sufficient water-power, the cost of the manufacture of alumina will be reduced, thanks to the valuable by-product of sulphate of ammonia, from 200 fr. to 50 fr. per ton, a net saving of 150 fr. per ton, or 300 fr. per ton of aluminum. The United States rights are stated to have been conceded to a subsidiary company with large financial resources, and licenses will probably be granted by the parent company for working the patent in other foreign countries.

The production of ferro-alloys and patent steels in the electric furnace grows apace in Savoy, there now being twelve factories engaged in this branch of the industry. The well-known works at Ugines (Savoie) for working the Paul Girod process of producing electric steel of great resistance have lately turned their attention to armaments, and have supplied [illegible] to the French and Russian [illegible]

EXTENSION OF AN OUTFALL SEWER.

A very interesting method for the extension seawards of an outfall sewer is described by Mr. John S. Brodie, M. Inst. C.E., borough engineer and surveyor of Blackpool, England, in a paper read recently at the conference of engineers and surveyors, held in connection with the annual congress of the Royal Sanitary Institute at York. The following abstracts are taken from the paper:

The old outfall at Gynn, Blackpool, was 1,304 feet in length, and consisted of cast-iron flanged pipes, 3 feet internal diameter, in 6-ft. lengths, bolted together and supported on timber piles and cradles. This outfall was laid in 1898, at the cost of £6,755, or at the rate of £15 10s. 9d. per linear yard. The work in 1898 was carried out by a contractor, and was never really completed to its intended length, which was 1,400 lin. ft., on the ground that the difficulties in connection with stormy seas and deepening water were so great that further extension was impracticable. Since then, sand banks have formed seaward of the old outlet, and it has been found necessary, in order to prevent the sewage from lodging on the foreshore, to extend the outfall across the recently formed sand banks into deep water, seaward of the same.

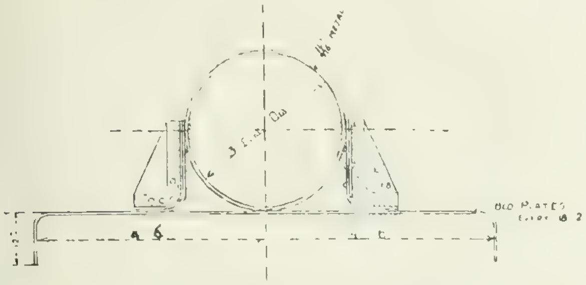

Fig. 1.—Cross Section Through Tube.

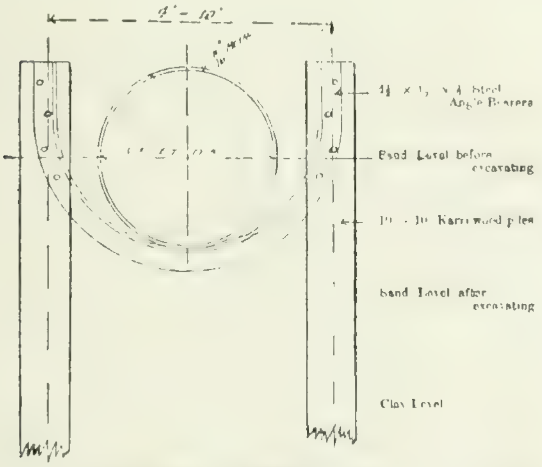

Fig. 2.—Cross Section Showing Piles and Cradling to Receive Connecting End of Tube.

The present extension has been made by means of a continuous steel tube, 3 ft. internal diameter, of solid welded pipes, in 18-ft. lengths, formed of open hearth steel, 11/16 in. thick, riveted together with cover straps 10 in. wide, 11/16 in. of thickness, with a double row of ⅞-in. rivets, spaced 3 in. centre to centre. The quality of the steel was such that the ultimate tensile breaking stress averaged 26 tons per square inch, with an ultimate elongation of 20 per cent. in 8 in. The whole of the tube, both inside and outside, has been heavily coated with an improved bituminous preservative. In order that the new tube should fit properly on to the flanged end of the old outfall, 10-in. square Karri wood piles were driven on each side of the trench at intervals of 6 ft. centre to centre, and connected by half-timber walings, to which close timbering, 3 in. thick, was secured, for a distance of 86 ft. seaward of the old outlet. The tube was built up for a total length of 600 ft., in the foreshore above highwater mark, at a distance of 3 miles along the coast line from its ultimate destination. In order that, when laid, the tube should not be subject to a rolling or rocking action on the sea bottom, caused by heavy on-shore gales, transverse steel bed-plates, 9 ft. long by 12 in. wide, and 11/16 in. in thickness, turned down at the ends for a length of 12 in., as shown in Fig. 1, were riveted to the tubes at 18 ft. centres, except for the 86 ft. length referred to above where the tube rests on the Karri wood and steel cradles.

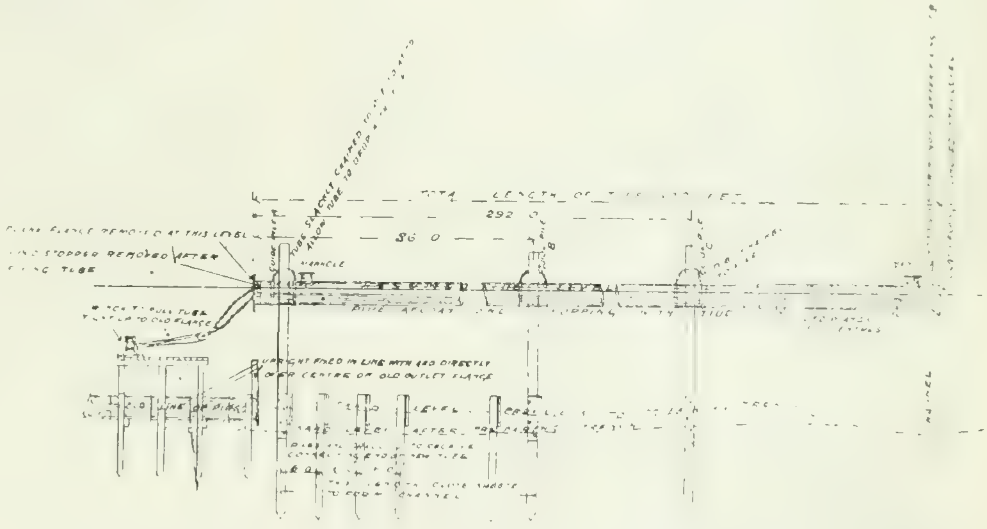

Fig. 3.—Longitudinal Section Showing Method of Dropping Tube in Position.

After being completed, the tube, which is provided with a 24-in. manhole and cover at each end, and also with blank flanges at the open ends, was filled with water and tested to a pressure of 50 lb. per square inch, at which pressure it was found to be perfectly tight. Timber watertight stoppers, easily removable, were then inserted at each end of the tube, close to the manholes above referred to, and caulked up watertight. The blank flanges were then securely fastened to the ends of the tube, and the manhole covers on the two manholes, one at each end, were also secured and made perfectly watertight. The tube was then launched from above high-water down the foreshore, to such a level between high and low water marks as would enable it to float with a 24-ft. spring tide. It was then floated into the sea, and towed by means of a steam tug for a distance of 3 miles, and was adjusted at high water over the trench, by means of guide piles, as shown in Fig. 3, where it was ultimately intended to lie. The blank flanges at both ends were then removed, the temporary stoppers maintaining the tube afloat. On the tide receding, the tube dropped down into its permanent position, the flow of sewage being held up temporarily by the shore penstock valves; the shoreward-end flange was then bolted up to the flange of the old cast-iron pipe, by means of 12 1⅛-in. steel bolts, and so secured in continuity of the old outfall. The manholes at both ends were then opened, the temporary timber stoppers were removed, the new outfall was then ready for the passage of the sewage.

The cost of the steel tube, which was constructed under contract by Messrs. Clayton, Son & Co., Limited, of Leeds, was £1,358, and the cost of launching, floating and laying was £592, a total cost of £1,950, or at the rate of £9 15s. per lineal yard.

Fig. 1 shows a plan and section of the new outfall tube sewer.

Fig. 2 shows the cross-section of the sewer as laid on the cradles for a length of 86 ft. seaward of the end of the old outlet.

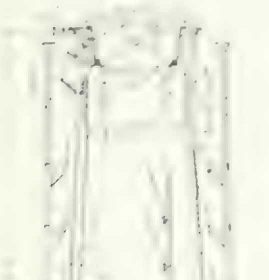
Fig. 3 shows the tube afloat, dropping down into its position on the receding tide.

The tube was manufactured and delivered on the foreshore at Blackpool by Messrs. Clayton, Son & Co., Limited, of Leeds, and the launching, floating and laying has been carried out departmentally under the author's assistant, Mr. H. Banks.

◆

A NEW THIN-LINED BLAST FURNACE.

The construction of a blast furnace of the new thin-lined water-cooled type, which has recently been put in operation, is described in the Cleveland Iron Trade Review. This furnace was built for the Eastern Steel Co.—formerly Warwich Iron & Steel Co.—at Pottstown, Penn., by F. C. Roberts & Co., of Philadelphia. It is the third of a group of furnaces owned by the company, and is arranged to be used with the stoves and power equipment of either No. 1 or No. 2 stacks.



Section Through Thin-Lined Blast Furnace.

The stack is 85 x 20 ft. The framework, including the columns, is of wrought steel. The top platform, charging apparatus, etc., are supported independently of the furnace shell by columns resting upon the main columns which support the furnace. Platforms are provided at various levels so that all parts of the furnace casing may be readily accessible. The lower portions of the furnace columns are enclosed in cast-iron casings filled with concrete. The in-wall is cooled by water carried and distributed by a spiral trough of the Roberts type. The waste water from the tuyeres and bosh-plates is delivered by different points in the spiral trough by an electrically driven pump. The trough is connected to the furnace shell by top bolts, which do not pass through the shell, thereby preventing the possibility of water entering the furnace around the bolts. A washer is provided around each bolt and between the trough and the shell. As a result, there is an opening between the bottom of the spiral trough and the shell which is continuous except for the thickness of the bolts.

At the lower end of the spiral trough the water is discharged into a horizontal trough which in turn is connected to the drainage system. The construction and operation of the spiral trough is such that while some of the water circulates around the spiral a large quantity passes through the openings at the bottom to the courses of the spiral trough below and continues its flow to the horizontal trough at the lower end of the spiral. In passing from one course of the spiral to that underneath, the water is in immediate contact with the furnace shell, thereby forming a thin film over all of the plates. The effect of a well-distributed spray is thereby secured with the additional advantages that the side of the spiral trough prevents the wind from interfering with the distribution of the water.

The bosh is enclosed entirely in a wrought steel casing having openings for the insertion of the bosh-plates. The construction is of the Farrell-Roberts type. The bosh-plates are held securely in position by angles on the inside and outside of the steel casing, the former angles being above and the latter below the bosh-plates. The steel casing enclosing the bosh extends downwards to a point below the top of the hearth jacket and is provided with openings for the tuyeres, cinder notch and the run of bosh-plates below the tuyeres. The hearth jacket is made of wrought steel plates which enclose a series of water-cooled cast-iron plates. Tht furnace mantel is simple in construction and a continuous wrought iron casing is provided which extends from the top of the hearth jacket to the top of the furnace. The hopper is supported by an annular ring, the construction being such that the leakage of gas around the furnace top is rendered impossible. The furnace is equipped with 10 tuyeres and two cinder notches.

The brickwork of the stock line is protected by Cook high-carbon steel plates. The downcomer is connected to the furnace top by four branches equally spaced around the furnace, each connection being provided with a vertical pipe extending 22 feet above the furnace platform and is equipped with a Roberts relief valve. In the event of a slip these valves permit the escape of gas, but prevent the discharge of ore, coke, etc. The furnace charging apparatus is of the Roberts skip hoist design connecting below with the stock transfer system, which supplies all the furnaces.

This stack has now been in operation about two months, with results entirely satisfactory.

◆

REPAIR OF FOUNDATIONS.

The underpinning of Winchester Cathedral, England, has been necessary on account of the serious settlement and displacement of some of the walls, cracking of masonry and distortion of arches. The original foundations have footings on timber grillages resting about 10 ft. below the surface on a 3 to 7-ft. stratum of peat underlaid by water-bearing gravel with pockets of silt between it and the peat in some places. Small pits were sunk outside the footings and from them drifts about 4½ ft. wide and 20 ft. long were tunneled diagonally under the wide footings. They were kept dry by centrifugal pumps down to a depth of about 18 in. above the silt when they were allowed to fill and the remainder of the excavation down to the gravel was dug by divers in water about 10 ft. deep. Bags of cement were carefully laid on the bottom under water and cut open. When set they formed a solid floor covering the bottom of the tunnel and enabling the latter to be pumped out and the work continued in the dry with mass concrete and concrete blocks built up to within 1 ft. of the overhead wall which was connected to the new footing with brick work.

THE TREATMENT OF WATER WITH CHLORINE.*

By Joseph Race, F.I.C. (Toronto's Filtration Plant.)

The use of chlorine as a disinfectant has developed entirely within the nineteenth century, and its general use followed directly in the wake of the commercial preparation of bleaching powder. This substance was often used in the early part of the century for the disinfection of sewage and water, and as early as 1854 its efficiency was so well recognized that an English Royal Commission recommended the use of this substance for deodorizing the sewage of London. In 1885 a special committee of the American Public Health Association stated that "taking cost into consideration, hypochlorites in general were the most efficient disinfectants available."

During the nineties many experiments with bleach and soda were made by Traube, Lode, Sickenberger, Kaufmann, and others, with the object of obtaining practically instantaneous sterilization of water for the use of travelers and troops in the field. Electrolytic processes were developed in 1889, when Webster in England and Woolf in America produced chlorine solutions from sea water, and used them for various purposes.

In 1897 bleach was used by Sims Woodhead for the sterilization of the water supply of Maidstone, England, subsequent to the outbreak of a typhoid epidemic. In 1904 and 1905, during the typhoid epidemic at Lincoln, a solution of sodium hypochlorite, commercially known as "Chloros," was used to the extent of approximately one part of available chlorine per million. This was carried out under the direction of Drs. Houston and McGowan, and was entirely satisfactory. A mawkish taste was, however, the subject of many complaints, and this was thought to be due to the action of the alkaline solution of chloros on the organic matter present.

Dr. Rideal has successfully used a form of electrolytic chlorine (oxychloride) at Guildford, England, for the treatment of water and sewage. Various combinations of chlorine were tried on the rivers Seine and Vanne in France, and at Meddlekerke and Ostend in Belgium. In North America Chlorine was first used on the commercial scale for water purification at Boonton, N.J., in 1908, and at Budby Creek, Chicago; since that date, the development of the process has been so rapid that over 200 cities are said to be using it at the present time.

In connection with sewage purification, the German experimental work at the Hamburg Hygienic Institute by Proskauer and Elsner in 1897, and later (1904-1905) the work of Dunbar and his associates, proved the practical possibilities of chlorine. In 1906 the Royal Testing Station at Berlin confirmed these results. In America, Phelps (1906), of the Massachusetts Institute of Technology, developed this branch of disinfection and carried out the first practical trial at Red Bank, N.J. Kellerman, Pratt, and Kimberley have also made experiments in this direction.

At the present time chlorine treatment of water or sewage is recognized in England and on this continent as a process capable of yielding excellent results at very low costs, but owing to certain disadvantages inherent to its use, it cannot be applied indiscriminately to all disinfection problems. It ought to be regarded mainly as an emergency measure, and secondarily as an adjunct to other forms of purification to provide an additional factor of safety. Each case in which the use of chlorine is suggested should be considered separately, as, except under strictly limited and peculiar local conditions, it cannot be regarded as a substitute for other purification processes. At the present time the problem is not how to use chlorine, although this phase cannot be considered finally solved, for the disinfection of water and sewage, but under what conditions it should be applied, how much it is desired to accomplish, and what amount of supervision is necessary. The views held by many German sanitarians are very different; they have not the high opinion of the process that prevails elsewhere, and generally regard it as inefficient. They severely criticize the bacteriological methods of the workers using gelatin plates for determining the efficiency, and give preference to enrichment methods. A study of their methods of applying chlorine to water shows that instead of using small quantities of disinfectant and allowing prolonged contact, they have employed as much as 40 parts per million of available chlorine with a ten minutes' contact, the excess being then removed by reducing agents, usually sulphites. Even with these large amounts, typhoid and cholera germs were not invariably destroyed, as in many cases the bacilli could be found after treatment, by means of enrichment in broth. Unless the view be taken that one single bacillus is sufficient to create infection in a susceptible individual, the criticisms of the German workers are not well founded, and their methods must be regarded as too stringent. The decreased typhoid death-rate in Toronto and other cities subsequent to the use of hypochlorite treatment is conclusive proof of the efficiency of the process, and refutes the theories of our German confrères.

The general principles regarding the action of hypochlorites are fairly well understood, but the details differ in every case and must be determined, as a full knowledge of them is essential to successful and efficient operation. The active constituent of hypochlorites for disinfecting purposes is chlorine, which liberates oxygen in a nascent condition when these substances are mixed with water. Nascent oxygen in small quantities inhibits the reproductive faculty of micro-organisms, and in large quantities kills them. It should be remembered that the results of chlorination are largely judged by the bacteriological results obtained, and, in these, the enumeration of the bacteria present plays an important part. The methods of counting the bacteria at present in use are dependent upon the ability of the organism to reproduce at such a rate as to form a visible colony within the period of incubation. Any substance which prevents the appearance of a colony during the period of incubation would be regarded as a disinfectant, but this does not imply that it kills bacteria. All substances known as disinfectant probably act at antiseptics in small quantities, and as germicides in larger ones, the line of division being imperfectly defined. The following tables show the action of chlorine on micro-organisms in water:—

City water is water drawn from the tap at the John Street pumping station and represents the main Toronto city supply approximately an hour after treatment by hypochlorite.

Control is water from the same original source as treated water, but not treated by hypochlorite. In order to make the bacterial counts in this water approximately comparable with the counts obtained in the treated water shortly after treatment, the original high count is reduced by dilution of the sample with water of the same kind sterilized by boiling.

Plating. In the column marked "Plating" are given the time intervals in days or hours between the time when the several Petri dishes were plated.

Count after—hours. In these columns are given the bacterial counts made on the several plates after the stated periods of incubation at 20 deg. C.

---

* Paper delivered to the Society of Chemical Industry on May 16th, 1912, and published in the journal of the society.

Ratio. In these columns are given the ratios between the bacterial counts on the same plates at the different periods of incubation, as indicated. These ratios indicate the relative increases under the different conditions.

Original sample, untreated, shows the bacterial count in the control sample, before dilution with sterile water, and corresponds also to the count before treatment in the Toronto city water or in the water used in the laboratory experiment.

It is evident that chlorine, in quantities smaller than 0.25 [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] the growth of bacteria [illegible] [illegible] [illegible] One part of available chlorine per million acts as a germicide, and there is no evidence of revivication. Since small quantities retard the growth when placed in such a suitable media as nutrient gelatin, it is probable that reproduction in water with a low organic content would be still further diminished. This is also indicated by the results.

From the results of these experiments and many others of a similar nature, it was decided to abandon the two-day incubation period recommended by the American Public Health Association and to count all plates on the third day. Three days is the period during which the formation of visible colonies proceeds most rapidly, and very little advantage can be gained by increasing it to four days. A three-day incubation period raises the standard of quality if numbers are given any consideration, and eliminates the anomalous results so often found when counts are made of chlorinated waters.

In this connection it is interesting to note the experience of Clark and De Gage, at Lawrence, Mass., during 1909. In the report of the Board of Health, page 319, 1910, they state: "It has frequently been observed that the numbers of bacteria determined at body temperature in the disinfected samples were much higher than the numbers determined at the usual room temperature. This phenomenon of reversed ratios between counts at the two temperatures has been occasionally observed with natural waters but a study of the records of many thousands of samples shows that the percentage of such samples is very small, not over 3 to 5 per cent. On the other hand 20 to 25 per cent. of samples treated with calcium hypochlorite show higher counts at body temperature than at room temperature. Similar counts have been noted elsewhere where waters are being treated with hypochlorites, but in many cases such results have been considered abnormal and have been omitted from the records. A phenomenon which has a frequency of 25 per cent., however, cannot under any circumstances be considered abnormal, and the omission of such counts from records is entirely unjustifiable. A careful study has been made of the conditions under which such reversed counts occur, and it appears that these counts are found in a considerable percentage of samples of water, sewage, etc., in which the room temperature counts have been reduced to less than 100 to 200 per c.c. by the use of hypochlorites, permanganates, and other oxidizing agents. A study of the types of bacteria remaining after disinfection shows that the proportion of spore-forming bacteria is practically the same after disinfection as it was in the untreated water, and the appearance of the reversed ratios apparently cannot be attributed entirely to the non-destruction of spores. The true significance of this phenomenon cannot be stated at the present time. It is evident, however, that, if the body temperature counts are [illegible] and reliance placed upon those at room temperature, a [illegible] and possibly a dangerous interpretation may be made [illegible] the quality of the water which has been treated with hypochlorites."

Available chlorine equals 4.0 parts per million. Treatment in laboratory.

[illegible] [illegible] possibly [illegible] [illegible] [illegible] previously mentioned, and the phenomenon would probably disappear by increasing the period of incubation.

Chlorine Treatment of the Supply of the City of Toronto.—The city supply is obtained from Lake Ontario at a point approximately 2700 feet south of the south shore of Toronto Island. The water is conveyed by means of a six-foot steel conduit to the north shore of the island where it descends a shaft (100 feet deep) and is then conveyed under the Bay in a tunnel 8 feet in diameter to the main pumping station where it is pumped directly into the distributing mains.

Under normal conditions the treatment of the water with chlorine does not present serious difficulties. The turbidity is low, coloring matter absent, and the organic content comparatively low. Successful treatment depends upon two factors, viz., perfect admixture and sufficient period of contact. The early experiences with the city supply seemed to indicate that the second factor was the more important, and this point is clearly shown in the following tables:—

Bacteria per c. c. gelatin 3 days at 20° C.

Date	Sampling point	Count

* This sample represents water which has been partially stored in a high pressure service reservoir.

The treatment takes place at the north end of the island, the bleach solution being added to the water as it descends the shaft to the Bay tunnel. The capacity of the tunnel is such that with a normal consumption of 43 million gallons per day, the period of contact before reaching the main pumping station is approximately 50 minutes.

In the spring of 1911, when the Health Department decided upon the treatment of the island supply, it was thought that owing to the water going directly into consumption after treatment with chlorine, insufficient time would be given to reap the full advantage of the process. It was, however, decided that chlorine treatment should be used, and a mechanical appliance was devised by the chief engineer of the Island pumping station by which a constant amount of disinfectant could be added and perfect admixture ensured. This apparatus consisted of a small plunge pump, the piston of which was connected with the piston of the main supply pump and was fed with bleach from one of two storage vessels. Check valves were placed on the inlet and outlet of the small pump. As each stroke of the large pump corresponded to a stroke of the small one, by determining the relative quantities delivered by each it was possible to fix the amount of chlorine added by varying the concentration of the bleach solution. Perfect admixture was obtained by injecting the bleach solution into the water by means of a perforated injector. The process worked very satisfactorily, combining a very high efficiency with a low cost.

Samples of water were taken at a point only a few yards distant from the pump, and although the time elapsing between treatment and examination never exceeded 15 minutes and was usually much less, almost sterile water was obtained throughout the whole season. The results were as follows:—

Island Results.

1911.	Available chlorine parts per million.	Bacteria per c.c.		Percentage of samples of treated water showing typical *B. coli* in		
		Raw water.	Treated water.	50 c.c.	10 c.c.	1 c.c.

October	0 50	1,256	15	Nil.	"	
November.	0-50	6,098	4	"	"	.

Samples taken at various points in the distribution mains showed greater numbers of bacteria than were found immediately after treatment, and an increase in the amount of chlorine used had no appreciable effect on these increases. Blowing out the mains effected a slight reduction, but only of a temporary nature, and several hours' treatment with a strong solution of chlorine (4 parts per million) also gave but little relief. As B. coli was almost invariably unmoved, even when 100 c.c. were tested, the phenomenon must be ascribed to the growths in the mains and not to a revival of the original flora. The period of time required for the water to reach the points where increases were found was almost invariably less than one hour, and as revival could not take place in such a short time additional evidence is furnished in favor of the theory of contamination with secondary growths. Despite these increased counts, the process must be considered an excellent one and efficient admixture the essential feature for obtaining successful operation.

On Toronto Island, one million gallons per diem were treated during the summer season, and since it was first installed in May, 1911, the process has been put into operation at West Toronto and Sarnia, Ont., with equal success.

Chlorine-treatment in Conjunction with Filtration.—It is well known that turbidity reduces the efficiency of the chlorine-treatment, and since in the case of the Toronto supply an increase of turbidity is usually accompanied by increased pollution, the chlorine treatment of the raw lake water can only be regarded as a temporary expedient. Its use as such has been entirely justified as there is no doubt that the adoption of the process for the city supply has resulted in a decreased typhoid mortality rate. In 1910 the rate was 43, and in 1911, during the whole of which chlorine was in use, the rate was decreased to 20.

Until the system of slow sand filters recently put into operation had demonstrated its ability to sufficiently purify the water supply it was deemed advisable to continue the treatment with chlorine, and the effect of the reduction in turbidity and organic content is easily observable in the table given below. The filtration plant was first operated on January 4, 1912, so that the beds have not yet matured. It will be noticed that the efficiency is rapidly increasing despite the high rate of filtration (5.3 million gallons per acre per day).

As a result of prolonged incubation of city tap water after filtration and chlorine treatment, the following numbers of bacteria per c.c. at 20 deg. C. (average of 12 samples) were counted:—After 2 days, nil; after 3 days, 0.75; 4 days, 3.0; 5 days, 7.0; 6 days, 10.0.

Chlorine treatment of the city supply was commenced in May, 1910, but no results are given until April, 1911, as gelatin counts were not made until this latter date. From this date onwards there has been a steady progressive increase in efficiency, and the reason for this can only be attributed to a gradual removal of organic growths in the large distributing mains. No evidence of revival has been found within the period of time the water remains in the system, as the count decreases with increased period of contact, the best water being invariably found at the points farthest removed from the pumping station.

That is the reverse of the experience at Cincinnati with chlorine treatment of filter effluents. Elms (Eng. Record, Vol. 63, p. 472) finds that although the water at the reservoir appeared practically sterile, very much larger counts were obtained from city tap samples, and he attributes this to disturbances of the bacterial flora and secondary growths. The difference between the Toronto and Cincinnati results may be due to the presence of a larger amount of easily oxidized organic matter in the latter supply. Elms (loc. cit.) has shown that the efficiency of the process is inversely proportional to the amount of easily oxidizable matter present and that large increases of bacteria are common in such samples following a temporary reduction.

The point of application of chlorine used in conjunction with filtration systems varies in different countries, English practice being to apply it to effluents only, and American usually to treat the raw water. In mechanical plants where coagulants are used it is convenient and economical to add the bleach prior to sedimentation, but the full advantage of the bleach is not developed in this method as the chlorine is acted upon by the full organic content of the water. Furthermore, the Lawrence, Mass., experiments have shown that when small quantities of chlorine are used (less than 3 parts per million) in conjunction with coagulants the action is soon complete and that subsequent storage increased the bacterial count from 100 per cent. to 670 per cent. There is an increase when chlorine is not used, but not nearly so marked as these figures indicate. These factors detract from the efficiency of the plant and better results can undoubtedly be obtained by treatment of the filtrates. This is proved by the Cincinnati results.

Any excess of chlorine added to water is considered by many to be removed by filtration, but of this there is no proof. Chlorine after addition to water exists in various forms—as free chlorine, hypochlorous acid, and in combination with organic matter. The two former can only be removed by special methods, such as the "Dechlor" and "Ferrochlor" processes, and although a portion of the latter is undoubtedly removed by sand filters, filtrates are obtained [illegible]

Experience with slow sand filters shows that chlorine [illegible] formation of the "blanket" layer, and retarding the bio- [illegible] During the chlorine treatment of the prefiltered water at Lincoln, [illegible] there is almost invariably an increase in the bacteria grow- [illegible] in contact beds.

Some experiments on sand treatment, made in the filtration plant laboratories, indicate a similar action, and two typical examples are shown in the following tables:—

Experiment 1.

Available chlorine in liquid parts per million.	Bacteria per gram of sand after		
	3 hours.	24 hours.	48 hours.
Nil.	70,000	—	—
0·1	7,200	20,400	12,800
0·3	5,240	6,400	11,200
0·5	5,120	4,700	10,800
1·0	1,000	8,800	20 400

Experiment 2.

Available chlorine in liquid	Bacteria per gram of sand after		Typical B. coli after 24 hours				Free chlorine after 24 hours.	
	3 hours	24 hours	100 gr	10 gr	1 gr	0·1 gr	Without acidification	After acidification
Nil.	[illegible]	[illegible]	+	+	+	—	—	+
[illegible]	[illegible]	[illegible]	—	—	—	—	—	+
[illegible]	[illegible]	[illegible]	—	—		—	—	+
[illegible]	[illegible]	[illegible]	—	—	—	—	—	+
[illegible]	[illegible]	[illegible]	—	—	—	—	—	+

The relative weights of water and sand were as 1 : 2.

It is observable that the effect of large doses of chlorine is first to reduce the bacterial count, but the reduction is not maintained and the subsequent increase is abnormally rapid. The conditions were evidently unsuitable for the reproduction of B. coli, and it remained inert.

From a consideration of all the available data there is no doubt that if chlorine is to be employed to full advantage, it must be added to the filter effluents. The turbidity, color, and organic impurities of a raw water are not apparently reduced by chlorine, but they are acted upon with consequent loss of available disinfectant.

The disadvantages of the addition of chlorine to prefiltered water may be summarized thus:

Mechanical filters: Reduced efficiency of chlorine.

Slow sand filters: Reduced efficiency of chlorine and reduced purification by filters per se.

Aesthetic Considerations.—Any compound of chlorine which liberates the free element on addition to water has a tendency to impart a distinct taste and odor to it, and when present in amounts exceeding 1 part per million of available chlorine it can generally be detected by the senses. This is the result of many experiments with Lake Ontario water, and although in some cases quantities smaller than 1.0 part per million could be occasionally detected, many blanks were also said to contain chlorine so that many of the positive results were due to auto-suggestion.

The taste of chlorine is sharp and acid, and the odor pungent, but these should not be confounded with the sensory characteristics of natural untreated waters. Many organisms such as Uroglena, Volvox, and Eudorina, impart a distinctly fishy taste and odor to the water in which they grow, and this is especially noticeable when the water is warmed. Uroglena probably effects this by the rupture of the oil sacs which it contains, and as the products of decomposition pass into solution they cannot be removed by the usual forms of purification. The majority of complaints regarding water supplies which are treated with small quantities of chlorine are due to these natural and uncontrollable causes, and although samples are often said to taste of chlorine it will generally be found that chemical tests give a negative result. As the reaction with potassium iodide and starch in acidified solutions is at least five times as [illegible] complaints must generally be [illegible] In these cases the number of complaints will be found to bear no relation to the amount of [illegible] Typical examples of this [illegible] during the summer [illegible] in 1911. Many complaints were received during the early part of the season when the rate was only 0.20 part per million of chlorine, and these entirely ceased during the latter half of the season when the rate was increased 150 per cent. The nature of the complaint has been the same as in other places where chlorine is in use, that it caused colic and other human ailments, that cattle and other animals refused to drink it, that it injured plants, fish, and birds, and extracted abnormal amounts of tannin from tea. No reliable evidence was ever produced in support of these statements, and they ought, therefore, to be treated as myths.

Corrosion.—There is no doubt that chlorine tends to increase the corrosive properties of water, but when the amount present is very small, the increased effect is so minute as to be inappreciable. Chlorine accelerates the action on iron by increasing the number of hydrogen ions, which are, according to the electrolytic theory of corrosion, mainly responsible for the deleterious effects produced. No injury has been noticed in the pumps at the main pumping station where chlorine-treated water has been pumped continuously for over two years, but it must be remembered that actual "free" chlorine is generally removed by absorption during the 50 minutes' contact in the tunnel under the Bay. If chlorine were added to a water in excess of the carbonates present, it is easy to conceive that an electrolytic action would ensue in a pump constructed of different metals or alloys of metals. The water becomes an electrolyte, and corrosion would take place. If a contact period sufficient for the assimilation of the free chlorine cannot be obtained previous to pumping, it is a good policy to inject the chlorine into the discharge pipe of the pump. In the case of plunge pumps this can be done as previously described, whilst with centrifugal pumps, the plunger of the small bleach pumps could be operated by a water-wheel connected in the discharge pipe. Dr. Houston in the 5th Report of the Royal Commission on Sewage Disposal gives some results of experiments on the action of chlorine-treated waters on lead piping. These show that chlorine (as "chloros"), in amounts varying from one to ten parts per million, does not appreciably increase the plumbo-solvent action of either unfiltered or filtered river water. Some experiments have been made within the last few days with the Toronto supply. Raw lake water, filtered water, and water treated with 0.25 and 0.50 part per million of chlorine all dissolved the same quantity of lead in 24 hours. The amount is, of course, so small that it cannot detract from the hygienic safety of the supply.

In conclusion, I wish to acknowledge the assistance I have received from the many valuable suggestions that have emanated from Mr. F. F. Longley, the resident engineer at the filtration plant.

◆

WATER PURIFICATION AS ENDORSED BY THE ONTARIO BOARD OF HEALTH.

The following is an extract from a circular being distributed by the agents of the Ontario Board of Health at the Canadian National Exhibition at Toronto.

A level teaspoonful of chloride of lime should be rubbed into a teacup of water. This solution should be diluted with three cupfuls of water and a teaspoonful of the whole quantity should be added to each two gallon pail of drinking water. This will give .4 or .5 parts of free chlorine to a million parts of water and will in ten minutes destroy all typhoid and colon bacilli or other dysentery-producing organisms in the water. Moreover, all traces of the chlorine will rapidly disappear.

This method should be very valuable for miners, prospectors, campers, and those living in summer resorts where the condition of the waters might not be above suspicion

CENTRAL STATION ELECTRIC POWER FOR RAILWAY OPERATION.*

By Frederick Darlington.

Every engineering operation seeks to accomplish some practical result, which is measured by its financial worth or capacity to earn money by saving labor in doing something useful. There are no exceptions to this, but for railroad work, which will be the subject to-night, we often have to look further and deeper for the full measure of worth, than is usual in any other matters with which I am familiar.

In the manufacture of cloth, for instance, the problem is simple, that is, make cloth of a desirable quality, at a minimum cost; likewise in making steel rails or bricks or paper, or any article of merchandise, there is a definite result to be obtained and the final test of different methods is the cost and value of the product, which in such instances is readily determined. There is no such simple way to judge the merits of transportation work for it is far more complex than manufacturing or other lines of production. This is seen in the great diversity of rates and classifications under which railroad accommodations are sold. In freight business, for example, there are different rates for long hauls and for short hauls, for car loads and for part car loads, and various classifications almost without limit. This diversity has not, as many people suppose, resulted primarily from a desire on the part of railroads to "charge what the traffic will bear," but rather from necessity caused by differences in transportation costs, combined with differences in the value of services rendered. It is not necessary to enlarge upon this for we all know it would be fatal to the interests of both buyers and sellers of transportation on a ton-mile basis, or on a uniform basis of distance hauled, or on any direct measure of transportation. An equitable rate for carrying a ton of wheat from Chicago to New York City has very little relation to an equitable rate for carrying a ton of wheat twenty miles from a farm to a grain elevator; likewise, there is very little relation between the cost per ton of transporting a car load of wheat and the cost on a single ton in a part car load lot, and short hauls and part car load lots may be quite as important in the aggregate as long hauls. What I want to bring out is not the value of the work done by the railroads, immense and necessary as it is, but rather to point out the need for still more and different railroad facilities, and to show that the use of electric power from central station plants will benefit railroads and at the same time benefit all other operations requiring power.

There is a wide field for improvement in railroad service that can be best accomplished with electric power, especially for local transportation. The statement has been made that the money expended in wagon hauling freight to and from freight depots of one of the largest railroad systems in New England, is greater than the gross receipts of the railroad from its freight business, and I am inclined to believe that this will apply to other American railroads. It is certain that the cost of wagon hauling freight to and from railroads, is a heavy part of freight transportation. Also in passenger service the collection and distribution of passengers to and from railroad depots, is a matter of large cost and has an important bearing on travel. This is evidenced by the work of electric interurban trolley roads, the favorite field of which is in the territory tributary to steam railroads, where they have in many places greatly facilitated the local collection and distribution of traffic. I will not enlarge upon this for it is well understood.

---

* A paper presented to the American Institute of Electrical Engineers, January 18, 1912.

In comparing steam and electric power for railroads, the comparison should not be based on the relative cost of operating certain trains by steam and by electric motive power, but the comparison should be made between the best use of steam power considering the cost and value of the service rendered, compared with the best use of electric power, considering the cost and value of electric service. It follows from the wide difference in the nature of the two kinds of power, that the train weights, schedules, etc., and even the locations that are best for railroads employing steam power, will not always be best for electric power.

As far as distribution of power is concerned, independent of whether it is for railroads or for other purposes, it is demonstrated that wherever a large number of small powers are to be supplied in a limited territory it is more economical to distribute it by electricity than by any other known method. An example is seen in the case of textile mills, where power from steam engines or water powers was formerly generated at each mill and conveyed to various rooms and machines by series of shafts and belts. This plan has been widely superseded with electric drive whereby electricity is generated in a central plant supplying numerous mills and is used to operate motors for driving small groups of machines in each mill, or even for driving a separate motor for each machine. Likewise, in railroad work, electric motive power enables a profitable service to be rendered, with greatly subdivided motive power suitable for light and frequent trains that if operated by steam power would be too costly to be profitable in such small units. So it has been in every field where electric power has been extensively applied. The most important result has not been a cheapening of work that was previously accomplished by other means, but more and better work has been accomplished, and so it will be with the use of electricity on railroads and this betterment will not be confined to railroading, because there is an interdependence in electric power operations, whereby any extension of electric lines and increased use of electric power for any purposes, leads to development of more and better electric power for all other purposes. How this must always result can be predicted by using a little justifiable imagination to clear the point of view of natural bias in favor of present conditions and methods that have gradually become unfavorable for present needs.

Custom and habit often leads to the continued use of apparatus and methods for work that could be better met by new means. To appreciate this, imagine that a wholly new country, that is destined by natural resources to become rich and prosperous is to be opened up, settled and developed, and that some empire builder with a master hand and complete foresight could furnish the transportation and power facilities of the country. By means of electricity and the railroads, he could direct the development of the country. First of all by building railroads with electric motive power, he would at once provide the means of transportation that is always adopted where the population is sufficiently dense.

[illegible] transportation and [illegible] centres and settlements will naturally locate on the railroads with transmission lines along the roads, these various centres are tied together, forming the [illegible] power system. If a country is to have a [illegible] of [illegible] and prosperity, [illegible] would pay for transportation by electric power then the railroads should unquestionably be provided with transmission lines connecting the [illegible] lines carrying electric power along the railroads make the most economical means for distributing power for every purpose, and all the street cars, house lighting circuits, shops and factories along the railroad, would naturally derive their power from these lines, and towns and manufacturing centres are always attracted by convenient power, as well as by good transportation conveniences. Then again, a diversified and extended use of electric power within any area, increases the size of the power plants employed therein and accordingly reduces the cost of each unit of power generated.

A manager acting for a central power plant desiring to sell power to a city electric railroad system, recently put the matter as follows: To the banker president of the railroad, who has a reputation of being difficult to convince in any such matters as sacrificing or setting aside part of his property, the manager said, "Do you want to make a dollar?" To which, after the way of bankers, he answered, "Yes." Then the manager asked him if he "Would share the dollar with someone else who helped make it," to which he answered, "Yes, if he could not make it all himself." Then said the manager, "I will sell you power for your railroad at less than it costs you to make, and even so, I can make a profit on it, for you are making it in 2000-kw. units and I am making it in 6000-kw. units, and, therefore, at less cost than you are; but besides making it in larger quantities than you are, I am serving a great variety of companies and secure a more even and steady load than you do since you are making power for only one kind of service, namely, to operate an electric railroad; but in addition to these reasons, I want your business, because with your load added to my present load I can generate power in 8000-kw. units, and still further reduce my kilowatt-hour cost."

It is not a matter of opinion but of accomplishment that available central station power is a valuable asset to every prosperous settlement, just as are railroads and telegraph and telephone systems. As power machinery and methods of work that are not now adapted to the electric plant, are becoming obsolete or wearing out they are being supplanted by electric machinery and electricity is being installed in new works where foresight is exercised to realize the maximum benefit by centralization and unification of power.

Much that was sought by railroads long before electric motive power was available for their needs is now accomplished with electricity. Years ago Wellington in his standard book entitled "Railroad Location"—a book, by the way, that deserves a much more comprehensive title—pointed out that "In the sale of transportation the price that the consumer is able and willing to pay, is greatly affected by trifling differences of convenience." He emphasizes the importance of convenient local transportation facilities and says that "The loss to the railroad due to not supplying the best facilities might be borne if it meant simply a reduction of transportation tax upon the traveler or the shipper of freight." (In other words, less money paid to the railroad), but he asks, "How stands it with the traveler or shipper? They save indeed the two or three cents per mile, which the railway loses, but they have to pay the entire cost of cartage on their freight and pay for their own conveyance, besides suffering the annoyance and inconvenience, which they estimate at a good round sum." He says, "From poor transportation facilities, the loss is threefold: The cost to the public is greater. The receipts to the railroad are less. The traffic is decreased in volume." To quote still from Wellington, "This means from the point of view of political economy, and as a plain statement of fact, which would appear in census statistics, that the capital of the country and the world is less than it otherwise would be."

We can now add to Wellington's list of losses and state that poor transportation, when resulting from failure of railroads to employ electric power under conditions favorable to its use, will cause a fourfold loss, including the three losses enumerated and adding a fourth represented by the added cost of power, both for railroad working and for industrial uses, and in the fourth instance, as in the three enumerated by Wellington, this means, from the point of view of political economy, a loss to all—to the railroads and to the public alike.

While it has been one of the works of electric railroads to produce added values with better transportation facilities, it is not my intention to reiterate arguments for better local service with electric power as a means of increasing values. It is rather the purpose to accept the evidence of interurban railroads that electric power is disadvantageous for light and frequent train service, and from this premise to examine the conditions for its further application.

The general statements thus far made concerning central power supply and railroad operation, are all capable of verification by examining specific conditions, but, as I indicated at the commencement of this paper, a complete analysis to apply to all conditions is most complex. It will be possible for me to give here only a few results based on actual operations which may be used by those interested as a basis to compute what economy centralization and unification of power supply will secure at other places.

	Total cost per year	Cost per year per kw. of plant capacity	Per kw-hr.
Operating labor	$52,500	$2.10	0.100
Operating materials (exclusive of fuel)	15,000	0.60	0.025
Labor for maintenance of plant	15,000	0.60	0.025
Material for maintenance of plant	17,500	0.70	0.030
Total cost of power plant operation and maintenance, exclusive of coal per yr.	$100,000	$4.00	0.150
Add the cost of coal at $1 per ton for coal of 13,500 B.t.u. per pound	82,500	3.30	0.15
Note.—The fuel cost will increase as the cost per ton increases or the quality falls off			
Other expenses pertaining to power plant operation, such as administration, legal and general expenses	10,500	0.42	0.02
	$193,000	$7.72	0.35
Add for fixed charges on the cost of power plant	225,000	9.00	0.41
Total cost of power per yr. with coal at $1 per ton and a load factor 25 per cent	$418,000	$16.72	0.76

The figures given below are for the cost of producing electric power in steam plants carrying railroad loads under conditions that are widely prevailing in the United States. These figures are not exact costs taken from any particular power plant, but are average costs worked out from actual results in several steam plants on heavy railroad and other work, so shown as to permit easy analysis for varying conditions of load and for different fuel costs, etc.

The figures given are the cost, including fixed charges, of producing power in a 25,000-kw. steam turbine plant, containing five main units of 5000-kw. nominal capacity each, but capable of carrying 50 per cent. overload or more in emergencies.

The yearly production of power is assumed at 55,000,000 kw.-hr. or a load factor of 25 per cent. on a maximum load of 25,000 kw., which is the total nominal capacity of the five generators. It is equivalent to an average operation of all of the generators for 2,200 hours per year at their rated capacity.

Such is the cost of electric power generation by steam for heavy railroad operation and general central station service.

There are two factors in the foregoing costs which are liable to maximum variations, viz., the cost of fuel and the average load on the plant, as it is called, the load factor. The assumed maximum load of 25,000 kw. could easily be carried on four ordinary 5000-kw. nominal capacity steam turbine generators, and leave one square unit in a five-unit station. A 25 per cent. load factor is assumed above (25,000 kw. maximum load and 55,000,000 kw.-hr. per year), the result in thermal efficiency would be about 8.4 per cent. It is difficult to determine from actual results just what the thermal efficiency would be at other load factors, but as it is sometimes necessary to know this as a basis for arriving at the fuel costs under varying load conditions, the following approximate figures are given for these variations. The coal is assumed to contain 13,500 B.t.u. per lb.

It would be difficult to demonstrate in detail the economies that can be derived from combination of mixed power service from the above plant compared with power for only one industry like railroads, and an attempt at it would lead back to the same generalities that I have already stated, but analysis of the schedules of costs and thermal efficiencies for a 25,000-kw. plant, working at 25 per cent. load factor, proves the broad assertion that in power generation large stations carrying mixed loads afford the maximum economies. Take, for example, the cost of general expenses and of fixed charges and of power station labor and material, exclusive of coal. These things are little affected by the load factor, but even in so large a station as 25,000 kw. they amount to $13.42 per kilowatt per year, out of a total cost of power of $16.72 per kilowatt per year, with good coal at $1.00 per ton, or $20.02 with coal at $2 per ton, etc. Furthermore, even the fuel cost per unit of power generated will ordinarily be less in mixed service plants than on plants for railroad work only, since the former generally work at better load factors than the latter. The better load factor comes from serving a diversity of operations. Also with more operations the plant will be larger and for this reason as well it naturally has a better load factor and all unit costs are correspondingly less.

Yearly load factor (ratio of maximum load to average output)	Average operation per yr. hours	Thermal efficiency of plant	Cost of coal per kw-hr. at $1.00 per short ton
10 per cent	876	6.5 per cent.	0.20 cent
20 " "	1752	7.8 " "	0.16 "
25 " "	2190	8.4 " "	0.15 "
30 " "	2628	9 " "	0.14 "
40 " "	3500	9.8 " "	0.13 "
45 " "	3940	10.1 " "	0.125 "

There are other important advantages from centralization of power in large power plants, which will have important bearing on the future of central station business, for industrial and for railroad power. One of these has to do with obsolescence and its importance in this connection does not always receive the attention that it deserves. Another is the utilization of off-peak or secondary power, which so far has been very little realized, but which will increase in importance.

Obsolescence has long been the bugbear of electric companies that are striving to earn dividends, and centralization of power seems to be their best means of salvation. We all know that electric companies that were started fifteen or more years ago, whether they were for lighting or for railroads, or for whatever purpose, have found a large part of the cost of conducting their business has been due to the failure of apparatus to meet growing demands not so much because it was worn out as because it became obsolete, when increasing business required larger powers and improved machinery.

Good serviceable power plants became obsolete because they could not do the increasing work of later years, and were discarded because the use of power increased. Centralized power plants meet changing conditions because they are built for larger service and constructed on a unit plan that can be economically extended to meet growing demands.

The utilization of off-peak power will be promoted by the concentration at central points of large amounts of off-peak power, which can be more readily utilized as second class power than the same amount of off-peak power if scattered through a number of small generating plants.

There are several very promising methods in prospect for utilizing off-peak or secondary power when it is concentrated in large blocks, but it is not within the scope of this paper to go into a discussion of them.

Next, turn to the power transmission side of the problem. In this the results in favor of large mixed operations are even more striking than in power generation. It is a difficult subject to generalize on, but briefly, suppose that a central plant is located at a favorable point at a coal mine or a water power, and it is desired to transmit power from the plant. It often pays to run 100 miles of transmission line to pick up a large load, whereas for a small load, the cost of 10 miles of transmission may easily be too great. It follows that if the aggregate amount of power surrounding the power centre is not large, it will not pay to go far for it, and the economical distribution area may be restricted to a radius of 10 miles or less. But, on the other hand, if the aggregate is large, long distance transmission will pay and the combination of large amounts of power per mile of transmission on long transmission lines, covering large areas, gives a big connected central station load. In this lies one of the great advantages in favor of including railroad roads on central plants, viz., where the amount of power and lighting scattered through a territory for manufacturing and similar purposes is not sufficient to make it economical to install electric transmission for this alone and where the railroad business is not sufficient to pay to transmit for railroad power alone, transmission for the combined loads will often be highly profitable.

There is a well-known power transmission company that affords an excellent example of the advantage of combining as much power as possible in a given territory. Its business aggregates something like 60,000 h.p., connected on several hundred miles of transmission lines, and the yearly cost of transmission including all fixed charges and operation and maintenance of the transmission system, amounts to about $12 per h.p. per year, based on its peak load of 50,000 h.p. Its load is industrial power and lighting with a few street railways. In the same territory there is a total consumption of power exclusive of steam railroads approximately 225,000 h.p. which if all served for a single central power plant would produce a maximum load of probably 150,000 to 175,000 h.p., but for various reasons, one of which is the use of exhaust steam for heating buildings, factories, etc., [illegible] that it would be [illegible] to serve from [illegible] would [illegible] peaks of only about [illegible] to [illegible] h.p. [illegible] of steam railroad operation. The yearly cost of power transmission including all fixed charges for transmission [illegible] for serving [illegible] h.p. in this territory [illegible] h.p. [illegible] as now [illegible] at [illegible] per h.p. per year [illegible] with $12 per h.p. which is the cost of power transmission and distribution for 50,000 h.p. only.

[illegible] of the [illegible] railroad [illegible] in the same territory [illegible] that if all of the railroads used electric motive power exclusively, the railroad load would require a [illegible] of between [illegible] and [illegible] h.p., and if only the railroad lines carrying heavy traffic and frequent train service were electrified in the territory, the maximum load, if served from a central station, would be somewhere between 150,000 and 200,000 h.p., and that the yearly load factor of this railroad load, including freight and switching and passenger service, would be between 40 and 50 per cent. It is clear that if this load were added to the industrial and lighting load, it would greatly facilitate and cheapen the unit cost of distributing power from the central station.

In conclusion, I want to review briefly what the substitution of electric motive power for steam on existing railroads should include. It is not enough to say that it would require the construction of central station generating plants, of transmission and distribution lines, generally following the railroads and of electric locomotives to replace steam. These would all have to be provided, of course, but that is not nearly all that should be done. Unless we look beyond such facts we cannot even appreciate the problem before us, much less solve it. When the railroads are paralleled by transmission lines over which central stations supply electric power for their operations, then the country traversed by the railroads will be in electric power zones, where power for any purpose may be taken from the lines along each railroad right of way and these lines will connect large central stations together, so that transmission lines will network the country as railroads now do and will connect important centres for power, as railroads do for transportation. Into this network of transmission circuits central electric plants will pump energy that can be drawn off in just the right amount to supply the needs of each point included in the network.

When this is carried out, the distribution of power, which is the greatest problem in the way of almost universal use of central station electric power, will be overcome with the resulting economy in generation as well as in distribution, since the most economical conditions for both generation and distribution are where large amounts of power are supplied at the best load factor attainable, which results when the largest number of operations are supplied from a single system. Thus there are many places where railroad electrification will be profitable as outlined, where it would not pay to build transmission lines for the railroad load alone or for the industrial power and lighting without the railroad load.

* * *

THE OVERHEAD PLANT OF A MODERN TELEPHONE SYSTEM.*

By Sergius P. Grace.

(Continued from last issue.)

On a breakdown test, the insulation stood 15,000 volts, alternating, for 15 seconds before breaking down. The voltage was gradually raised to the above figure.

For a ten-year-old wire this is very remarkable, and if we could be assured that all the rubber wire that we have purchased would give the same results the drop wire part of the plant would prove very economical to maintain.

During recent years, with the many manufacturers in the field to supply the large demand, and the introduction of many kinds of rubber substitutes to just meet the specifications, I am afraid that our drop wires are going to cost us more than they would if the old quality of wire had been maintained.

---

* Paper read before the Philadelphia Telephone Society and published in the Telephone News.

The invention of the paper telephone cable and the use of the lead press to form the cover has been described so often that I will not weary you by repeating the details. One point I wish to bring out clearly is that originally lead cable was designed for use underground, for which purpose it is splendidly adapted.

Lead is a metal which should be used only under quiescent conditions, because of the readiness with which it crystallizes and cracks under repeated bending. I do not know the name of the genius who first found that lead cables could be successfully used overhead. He is to be congratulated that so unsuitable a material as lead has proved so successful for the purpose.

Let us consider what an unmated couple we have when we hang a lead cable on a steel rope. Lead has a temperature coefficient of expansion of .0000160 and that of a hard steel rope is .0000064. In other words, for any given change in temperature, a lead bar or cable sheath will expand two and a half times as much as a steel bar or messenger rope. In a 110-foot span, with a rise in temperature of 100 degrees Fahrenheit, a lead cable would increase in length 2.13 inches, while the steel rope would increase only .84 inch, leaving a surplus of 1,29 inches of lead which obviously must be stowed away somewhere.

The lead cable, by reason of its excess expansion, is forced into taking care of itself by moving into the pole dips or other bends or kinks along the cable. If the cable were free to move throughout its entire length and were placed on frictionless rollers, it would expand in a straight line and not into the dips and bends along the length of the cable. These dips or bends may be called nodes of least resistance into which the cable moves back and forth with every temperature variation.

These daily excursions of the cable into the dips and bends will, in a few months or seasons, cause deterioration in the cable and finally result in crystallization and cracking.

In the older forms of cable construction it was generally the practice to band the cables closely to the steel strands and leave at each pole a dip of four to six inches.

Realizing that there is a difference in expansion rates between the lead cable and the steel supporting wire, the only rational method of suspension is one that will permit the cable to take care of its expansion and contraction in long, sinuous waves, so that at no point will the stress in the lead go beyond its elastic limit. This can be done by long hangers, large rings or big pole clips.

I wish now to refer to the prevalent evil of tight messenger wires. There is a difference of opinion as to whether this makes a better looking job than loose messengers with uniform, slightly sags, but, as I will point out later, tight messengers have a most destructive effect on pole line construction and increase the difficulties from expansion and contraction troubles, which are the main cause of repairs and excessive depreciation.

A wire of uniform weight per foot, when suspended between two supports, will describe a catenary curve, the fundamental equation of which is

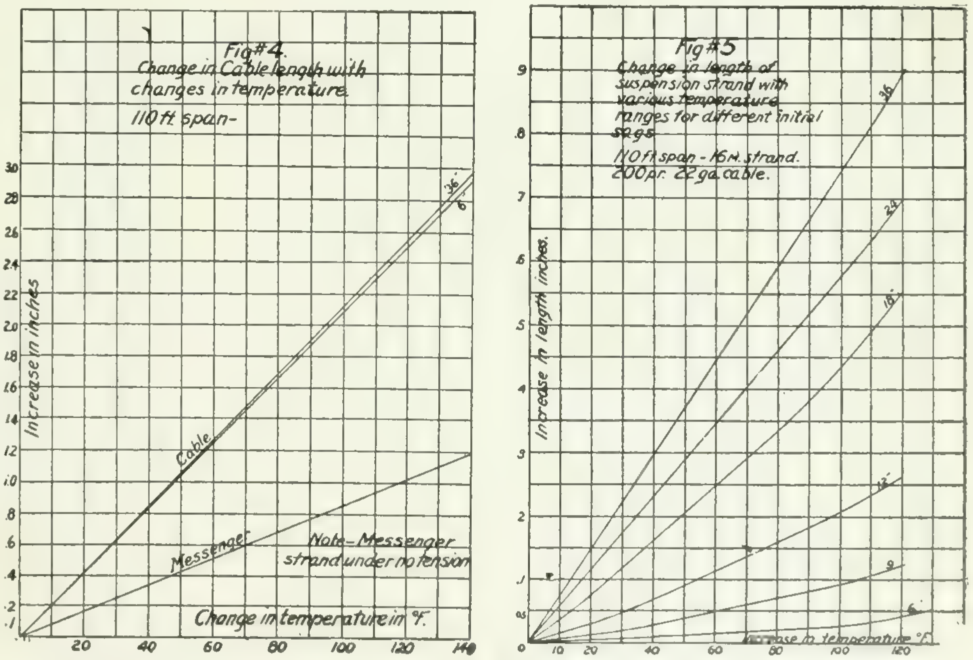
$$y = \tfrac{1}{2} a \left(\frac{x}{Ea} + \frac{—}{E} \, \frac{x}{a} \right) \qquad (1)$$

in which E is the base of the Naperian system of logarithms, x and y, coördinates, and a, the distance from the bottom of the curve to the horizontal axis. For catenaries of small deflection, the curve is practically that of a parabola, and we may write for the horizontal tension in the centre of the span the formula—

$$T = \frac{WX^2}{2d} + \frac{d}{6} \qquad (2)$$

in which W = weight per foot of wire and cable. X = ½ span in feet, d = sag at centre of span in feet. From this equation the curves in Fig. 3 were plotted

By referring to these curves, it will be noted how rapidly the stress in the messenger wire increases for a small decrease in the dip of sag of the span. For example, with a dip of 4.32 inches, the stress in the messenger wire supporting a 100-pair 19-gauge cable would be 27,500 pounds, and for a 50-pair cable 17,500 pounds. If, instead of a 4-inch dip, an 18-inch dip had been given these messenger wires and cables, the stresses would be 6,000 and 4,000 pounds, respectively.



Curves Nos. 4 and 5.—Showing Changes in Cable and Messenger Wire Lengths With Temperature Changes.

The standard sags which were worked out for our company are as follows:—

Span in feet.	Minimum sag in feet.
100	2
115	2½
130	3
150	4

These sags were determined with a view to producing the least strains in the overhead construction consistent with clearance and a reasonably good looking job.

Under these conditions, a 400-pair 22-gauge cable suspended with the standard sag will produce a stress in the messenger wire of only 4,203 pounds, or with a 16,000-pound messenger wire, a factor of safety of 4.

In addition to the great strain tight messenger wires place upon overhead construction, another peculiar effect is produced. A steel messenger wire is elastic, and, under a state of tension, will elongate to an extent dependent upon the modulus of elasticity of the material. When the stress is removed, the steel cable will come back to its original length, provided that we have not carried the stretching far enough to exceed the elastic limit of the material.

A tightly stretched messenger wire will be elongated nearly an inch in a 110-foot span, and its cross section will also be proportionately reduced. Now, under these conditions, if the temperature should increase, the sag will of course tend to increase an amount dependent upon the temperature coefficient of the material, but the increasing of the sag or length also has a tendency to reduce the tension in the wire and thus reduce the elongation which is dependent upon the modulus of elasticity.

Consequently, in a tightly stretched messenger wire, a condition of equilibrium will be reached in which it will be found that the length of the messenger wire will be increased but very little. Therefore, under these conditions, it is not a case of taking care of the difference in expansion between the lead and the steel, but, instead, almost the entire expansion of the lead will have to be taken care of and stowed away in some place. Obviously the movement which may be concentrated in a bend or pole dip, is very much greater than would have been the case if the cable had been placed on a messenger wire with a reasonable amount of sag and consequent small tension.

The formula which shows the relation between temperature changes and sags for an elastic wire is as follows:

$$a = \frac{1}{\text{[illegible]}}(d^2_1 - d^2_0) + \frac{\text{[illegible]}}{\text{[illegible]}}\left(\frac{1}{d_0} - \frac{1}{d_1}\right) \qquad (3)$$

when sag is expressed in inches and span in feet. In this formula.

a = temperature variation for small change in sag.

t_0 = initial temperature.

[illegible]

[illegible]

d_1 = sag at temperature t_1.

c = coefficient linear expansion per degree Fahr.

e = modulus of elasticity. A term expressing the relation of amount of extension or compression of material under stress, to the load producing that stress or deformation. It is load per unit of section divided by the extension per unit length.

[illegible]

s = cross section of wire in square inches.

By assuming small changes in the sag, successive values of "a" may be found from which curves showing variation [illegible]

[illegible]

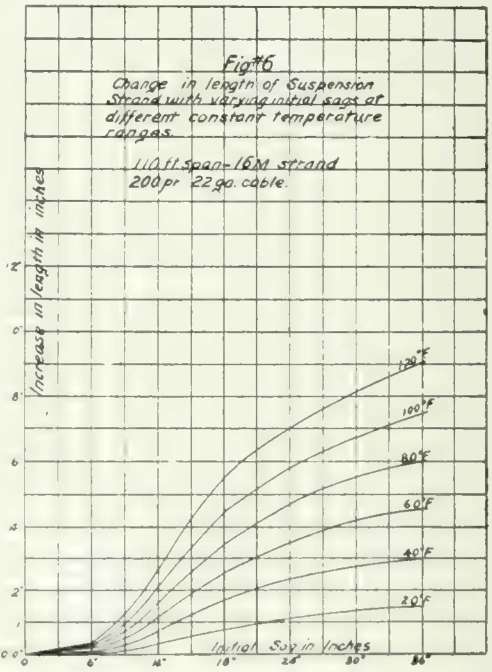
$$l_1 = l\,(1 + \frac{8d^2}{3l^2}) \qquad (4)$$

[illegible]

[illegible] For example, the increase in length for an initial sag of 6 inches for 100 degrees rise in temperature is only .025 inch, practically negligible, while under the same conditions with an initial sag of 30 inches, the increase in length would have been .7 inch, or 28 times as great. Curve No. 6 shows these relations in a different way, as the initial sags are plotted horizontally, and increases in length vertically for a series of varying temperatures.

It is clear from these curves how little variation is produced in the length of a tightly stretched messenger even with wide temperature variations.

In our standard practice, we specify a 30-inch sag for a 110-foot span. It may be assumed with safety that the daily variations in temperature will not exceed an average of 40 degrees, and a reference to curve No. 6 will show that above 30 inches initial sag, no material increase in length will be obtained for this temperature change. Consequently it appears that the standard 30-inch sag for this span is correct. In other words, with a 30-inch sag and average temperature changes, we realize 87 per cent. of the increase there would have been under a state of no tension in the messenger.



Curve No. 6.—Temperature Variation Effects on Messenger.

In case cables have been erected in the hot summer days, the reverse of the above expansion movements will take place. If dips have been left at the poles, cold winter weather will contract the lead cables and take most or all the slack out of the dips. On the other hand, if no dips have been left and the cable has itself been pulled up until no slack is left, the cold weather will have an extremely bad effect. This is because the cable will contract more than the messenger wire, and particularly so if it be a tightly stretched and elongated messenger, which will have the effect of taking the load off the messenger and throwing the major portion of the strain in the cable itself. Since a lead cable is easily stretched and deformed beyond its natural length by small stresses under the above conditions, the lead sheath will be permanently elongated and perhaps injured in many places. When the hot weather returns, this elongated lead sheathing will again expand at a higher rate than the messenger wire and show the familiar surplus of cable. The tighter the messenger is strung, the more aggravated will be these troubles.

Previous to the year of 1902, the practice in our company was to stretch the messenger wires very tightly and attach the cables closely to the messenger by means of marlin bands. This unfortunate method of cable erection marred what was, in most all other respects, an admirably designed and constructed aerial cable system of distribution. In the course of a few seasons, hundreds of breaks occurred, and when I came with the company, in 1902, it was one of the first problems passed to me for a solution.

It might interest you to know of some of the experiments we made at that time to determine the cause of the trouble. The general opinion was that the cracks were caused by the vibration of the poles and messenger wires, but both Mr. Snyder and myself felt sure that the principal trouble was due to expansion and contraction by temperature changes.

We placed a lead cable 67 feet long through rings on the roof of the telephone building. The cable has a 4-inch dip at one end, was fastened at both ends, but free to move along its length and expand into the dip. Around the cable we wrapped a resistance wire protected with a heat-insulating material. By passing current through the wire, we could raise the temperature of the cable to any desired degree. It was clearly shown that the cable was moved with temperature changes and that the coefficient of expansion was practically that of the lead sheath and not of the wires inside.

In order to determine the number of movements necessary to break the cable sheath in the average dip, a number of pieces of various size cables were bent with a dip of four inches and subjected mechanically to a movement of one inch along the cable. When the movements were made by a fast arm motion, it was found that 50 to 100 movements were required to break the sheath of the cable. When the movements were very slowly executed by the arm, it took from 200 to 300 movements to crack the sheath.

The cables with large diameters broke first, which was to be expected, since the angular opening at the surface of the sheath for a given movement would be larger because of the increased value of the radii. To make sure that the same results were occurring in practice, metal gauges were placed on existing cables to measure the increase in the dip and the movement of the cable along the span.

On many cables we were able to observe a daily longitudinal movement of the cable of one-half to three-quarters of an inch. All these experiments and tests prove very conclusively that our lead cables are constantly moving on the messenger wires because of temperature changes. We may, without exaggeration, imagine them to be alive and writhing and twisting about the supporting wires with the unceasing variations of heat and cold.

Unquestionably, because of these movements, aerial lead cables start to deteriorate from the day of their erection, and microphotographs of the molecular arrangement taken yearly would plainly show the changes in the molecular structure of the lead.

Another interesting phenomenon in overhead cables, is the effect produced by the difference in expansion rates of the entrained air in the cable and the lead sheath. Air has a greater coefficient of expansion than lead, and, therefore, when a cable is heated on a warm summer day, the air inside is compressed. If there be an opening anywhere in the lead sheath, the air will escape because of its compression; then, if a summer shower takes place, the cable is very suddenly cooled and the air inside will be rarified into a partial vacuum. This causes air to rush into the cable from the outside, and, as under these conditions there is usually water present on the surface of the cable, the water will be driven into the interior of the cable very rapidly and cause a serious case of trouble, which will take some time to locate and remedy.

In some of the older construction work, it was the practice to fill each joint with paraffin. In a few seasons it was noticed that nearly all these paraffin joints had a collapsed appearance. I believe this can be ascribed to the melting of the paraffin in very hot weather and its being driven each way into the cable by expansion. Then, if the cable was suddenly cooled by a shower, the paraffin would solidify and leave voids or vacuum pockets inside the lead sleeves. The outside air pressure would then force in and crumple up the lead sleeving.

A crystallization and cracking effect similar to expansion cracks is sometimes caused by the repeated blows of tree limbs.

Electric light and trolley crosses also play havoc with lead cables, and when a heavy arc is drawn, the lead will run in streams like so much water.

Lightning, as a rule, entering a cable does not burn large holes in the lead sheath, but the puncture is more like the hole made with a brad-awl or punch.

From time to time we have heard curious stories of various kinds of bugs and beetles devouring the lead sheath of telephone cables in California, Australia, and other parts of the world. There seems to be no doubt that there are several species of beetles which, for some strange reason, have aspirations to build a home inside the sheath of telephone cables. I understand that in California they have actually caught the bug in the act, and the state entomologist is now engaged in looking up his pedigree and ancestors.

Lead cables placed in boxes over vibrating bridges have also been a frequent source of trouble. This trouble would naturally be expected on account of the susceptibility of lead to crystallization and cracking, due to repeated blows, which they would receive in such a position.

Many times, in looking over aerial cable construction, it will be noticed, particularly if the messenger wires have been tightly pulled, that some of the cables will have expanded so much as to force themselves above the messenger wires. It is puzzling to account for this large amount of excess cable unless we remember the elongation of the messenger wire that takes place under tightly stretched conditions. It has been shown previously that a messenger wire stretched very tightly did not materially increase in length for large temperature changes. The same effect will be produced in a tightly stretched messenger wire if some of the corners give way or the anchors loosen up slightly.

If the messenger wire had not been elongated, this giving way of the corner or anchor would produce no change in its length, but since the messenger wire is tightly stretched, when the corner gives way, the tension will be decreased and the messenger wire will increase in cross section. Its length will actually be decreased.

Since the cable was not elongated, it is apparent that, with the shortened messenger wire, we will have a surplus of cable which can only take care of itself by pushing around and above the stand. This phenomenon will also be observed when a splice is made in the middle of a section and the splicer's carriage and guy rope has stretched the messenger wire beyond its normal elongation. When the weight of the splicer and carriage is removed, the messenger wire will shorten and produce an apparent increase in the length of the cable.

In conclusion, when we stop to consider that the lead telephone cable was originally designed for use underground, where the lead could be quiescent, it is a marvel that our engineers, construction and maintenance men have been so successful in keeping operative the many thousands of miles of aerial plumbing throughout the Bell system.

I venture to say, however, that our present form of lead aerial cable is not the final answer to the solution of aerial distribution, but that in the years to come, we will have a much more flexible cable with a sheath capable of withstanding the mechanical shocks and temperature changes of overhead construction.

Finally, at the risk of tiresome repetition, I am again going to say that one of our most important duties is so to design and construct the overhead plant that while it serves its proper purpose in the giving of efficient and economical service it will in appearance give the least offense to the public taste that every day is demanding more and more on the æsthetic side of the city beautiful.

NEW APPLIANCES FOR TESTING STONE PAVING BLOCKS.

Tests of paving materials as regards crushing strength and resistance to frictional wear have been conducted for the city of Paris, France, by its municipal laboratory for about 40 years. The equipment of this laboratory has been supplemented recently by the reconstruction and improvement of old appliances and the installation of new ones. This new equipment is described by Mr. Pierre Labordere, engineer of the Roads and Bridges Department, and Mr. Frederick Austett, Chief of the Paris Municipal Laboratory for Testing Materials, in a paper prepared for presentation at the 6th Congress of the International Association for Testing Materials at New York City, Sept. 3-7. An abstract of the paper follows:

Preparation of Test Pieces.—The preparation of the test pieces comprises two operations: Cutting to shape and finishing. The first operation is accomplished by means of a helicoidal wire, composed of three steel wires 2 mm. in diameter, each forming an endless band 30 metres long, running in vertical plane with a velocity of 7 metres per second. It is maintained in uniform tension by a counterweight and rests on the specimen to be cut. This latter is firmly secured on a plate, situated in the centre of a frame carrying the the pulleys which serve to guide the wire. The wire carries with it an abrasive material consisting of powdered sandstone and granulated steel, continuously moistened by a jet of water. The rate of cutting is 5 centimetres per hour in [illegible]

The operation of sawing with wire leaves irregularities on the surface of the specimens, which irregularities must be eliminated; and, moreover, the specimens to be tested must have perfectly flat and strictly parallel faces. In order to bring about this result a polishing machine consisting of [illegible]

Testing the Specimens.—[illegible]

[illegible]

[illegible]

The head of the tup is provided with a brake, which is set in operation by the effect of the impact and stops the mass instantly after the rebound, thus preventing the secondary impact due to successive rebounds.

The test specimen (a cube of 5 mm. side) is fixed in a box which, in turn, is bolted to the anvil base. This box is provided on all four sides with spring pushes exerting a uniform pressure of 6 kilos on the specimen it contains, through interposed steel plates. The cube projects from the box for a distance of 1 centimetre.

To prevent the tup from striking the cube slantwise in the event of the contact surfaces of the two being not exactly parallel, or of the upper face of the cube not being perfectly true, the cube is covered with a kind of cap of tempered steel, the perfectly flat inner face of which is applied to the upper face of the cube by means of lateral springs, so as to insure complete contact. The upper portion of the cap is spherical; and by this means each blow of the tup is transmitted integrally to the entire surface of the test cube. A note is taken of the number of blows required to produce the first crack; and then of the total disintegration.

The authors have been impressed by the imperfections of the machines for the test for resistance to attrition (wear under friction) typified by the Dorry machine used in France and consisting of a cast iron disc mounted horizontally and rotating in its own plane, the specimens of stone to be tested being placed in contact with the disc.

The test pieces being of rectangular section, whereas the different points of the disc in contact with same have a trajectory of concentric circumferences, the wear set up by is irregular, both as regards the disc itself and the test pieces. It is therefore somewhat difficult to measure the attrition produced; and the tests made with discs that exhibit irregular wear are difficult of comparison with one another.

A new machine which has proved thoroughly satisfactory has been designed and constructed for the resistance to attrition test.

It consists of a cast iron drum rotating about a horizontal axis. The blocks to be tested are placed in pivoted boxes sliding vertically in recesses, and are brought into contact with a generating line at the top of the drum. Powdered sandstone and a jet of water are delivered from a couple of calibrated funnels onto a point a little in front of the plane of contact with each test piece.

The drum has a diameter of 60 cm., in order that the arc on which the specimens rest may have a very slight curvature. A few turns of the apparatus are then sufficient to impart to the lower face of the specimens a curvature corresponding exactly to that of the drum surface. When this is achieved, the height of the test piece is measured, the measurement being repeated at the conclusion of the test.

To prevent the formation of grooves on the surface of the drum the following plan has been adopted: Each test piece, 6.5 cm. wide, is separated from the adjacent test piece by a distance of exactly the same width as the pieces themselves, namely 6.5 cm.

After every 1,000 revolutions, the cylinder is displaced on its shaft by a distance of 6.5 cm., the shaft being provided for this purpose, with two stops situated at each end and limiting the displacement of the drum in either direction.

In this way a very considerable number of tests can be performed with the apparatus without any sensible abrasion of the drum, and above all without the formation of grooves thereon. The apparatus is constructed to take 6 test pieces at once, the drum being [illegible] cm. long

THE COMMISSION FORM OF GOVERNMENT.

The problem of city government has been a difficult one to solve. Many forms of municipal government have been tried in the past thirty years in the United States, and, while some of these have shown distinct advance over preceding methods, still not one could be called an unqualified success. Mr. Oswald Ryan, of Harvard University, in a recent analysis of the real problem of Commission government, makes some interesting commentaries on this form of city government which has proved unusually efficient in the Western United States and in some of the Western cities of Canada.

The municipal needs of the present day are stronger than ever in their demand for a system which will ensure administration by experts. The increasing social and economic complexity of modern urban life has entailed burdens and obligations hitherto unknown to local government, and if the work of meeting these needs is not carried on with the assistance of permanent experts the cities must fail in their obligations. At the same time it is plain that government by experts alone is undesirable and out of harmony with American political ideas. A staff of permanent officials which is out of touch with the electorate tends to develop into a professional bureaucracy, tied up with red tape and unresponsive to the popular will and needs. It is, therefore, necessary that the expert should be under the constant supervision of the layman, who will thus form a connecting link between the professional staff and the people. In this way the permanent official will be brought into contact with the needs of the people, and the people, through their elected supervisors, will possess the means of controlling the permanent official.

It is precisely this adjustment between the professional and lay elements in the government which has been responsible for the marked success of the English borough governments. As in the commission plan, the legislative and administrative powers of the English borough are vested in the council, which is the sole governing authority. The actual work of administration is carried on by a permanent staff of experts acting under the supervision and control of standing committees of the council.

The principle underlying the organization of the commission system of city government is clearly in harmony with what American and English experience has shown to be the most effective working principle that may be applied to the government of cities in a democracy. The commissioner, being an elective official, can not be expected to be an expert official. Indeed, experts will never accept an office of such uncertain tenure as that subject to the fluctuating influence of politics. The commissioner may be an efficient unprofessional, supervisory official, however, acting in the same capacity as the English council committee: and in such a capacity he will reach his maximum efficiency. Under this clearly defined distribution of functions between the elective and the permanent official each official will exercise that kind of function for which he is best fitted. This proposition, clearly understood, settles the crucial point in the problem of commission government.

If the commissioner's function is defined as supervisory with respect to his relation to the administrative service, the question may arise: Will it not now become necessary to have a permanent expert department head working under the supervising commissioner? This question must be decided with reference to the character of the commissioner's duties. In the small city, where the affairs of the different divisions of the department are left to the charge of the subordinate officials, these duties would be comparatively light, and only the general direction of the activities should rest with the commissioner. Under such circumstances the commissioner would be able to direct the work without the aid of a permanent head. It is probable, on the other hand, that the work of directing one of the great departments of the very large city would be too onerous and too complex for the layman to discharge without the aid of a permanent administrative head, in which case it would be found necessary to institute the permanent official.

With the development of the commission plan into a more distinctly supervisory character, the people will have worked out a system of city government which does not differ in essential principles from that with which they started out, the council plan. The machinery of the commission government is more centralized and more responsive, but the relation between the elective official and the permanent administrative staff is common to both systems. It is upon these principles that the permanent efficiency of the commission government must rest, just as it was contempt for these principles that caused the failure of the reform municipal systems of the past thirty years. If the commission plan conforms strictly to these principles, there is reason to believe that it will not become the subject of a tale "full of sound and fury, signifying nothing."

THE TORONTO CITY ARCHITECT'S DEPARTMENT.

The inquest at the time of the Neilson building collapse brought to light considerable evidence which showed the necessity for reorganization of the Toronto City Architect's department. While there have been many rumblings since in the City Council as yet no action has been taken. We hope that the City Council and the Board of Control will seize the opportunity to get a strong man to take charge of this department of the city's work. The City Architect's department is in some respects the most important section of municipal activity. It is perfectly clear to all that some drastic action must be taken with regard to the present organization of the department. The protection of the public demands the appointment of a man at the head who is not only capable of handling the executive end of the work, but also a man who is well versed in the technical details. The ideal head for this department is a man well versed in the strength of materials, one who has made a special study of it, in fact. The various equations in the different handbooks it should be possible [illegible] If any improvement is to be made in the department, such a man [illegible] ability.

The [illegible] the Assistant City Architect did in the Neilson investigation ought not to be entrusted with this important work. Under a competent City Architect, however, he [illegible] versed in modern building materials and their strengths to put them in proper shape. All of the above facts demand that the Board of Control and the City Council appoint a man who possesses qualifications which fit him for the position. The history of civic appointments in Toronto has not been above criticism. The necessities of public safety, however, demand that all question of political expediency and personal pull be eliminated. *The Canadian Engineer* is interested, because it is not the artistic, but the scientific or engineering side of architecture which is at stake.

EDITORIAL COMMENT.

In recent comments on the new Canadian Pacific Railway building in Toronto, one of the Toronto daily papers speaks very favorably on the style of architecture and the general pleasing appearance of the building. While it is true that it is "a design peculiar to our age and country," we believe that the corner of King and Yonge Streets is no place for a sixteen-story building. It may be "satisfactory" and "satisfying" to certain members of the daily press, but it certainly will not be spoken of in such terms by the man living in its shadow. It is time that the City Council passed the ten-story limit amendment to the building by-law.

* * * *

Attention has been called to the fact that the British School of Architecture at Rome is inaugurating a scholarship in architecture open to all British students under thirty years of age. The scholarship is worth $1,000 per year, and is tenable for three years. The expectation is that a number of Canadian students of architecture will try for the scholarship, full details of which can be secured from the Department of State.

CHANGES DUE TO THE NEW WELLAND CANAL.

The construction of the new Welland Canal will necessitate a number of changes along the course of the first section of the old canal. It is understood that the government has under consideration the changing of the aqueduct under the Welland Canal necessitated by the crossing of the Welland River. Enlargement of this aqueduct would be extremely difficult. As an alternative it is suggested that the aqueduct be [illegible] and that lock gates be installed in the river at Port Robinson, raising the level of the water in the river to that of the canal. This would mean a raised elevation of [illegible] feet. Levees would then be built along the shores of the river to prevent flooding. A harb r and turning basin would be built at the intersection of the river and the canal. It is also reported that the government will construct a large [illegible] Lake Erie to provide a water supply for the [illegible] supplied from the canal.

LARGEST FLOATING DOCK.

The largest floating dock in the world was launched [illegible] at Birkenhead. It has been constructed for the British Admiralty. The dock is capable of lifting battle ships having a displacement of 32,-[illegible] accommodation for the [illegible] officers and crew.

MUNICIPAL TELEPHONE OWNERSHIP.

Some figures on the cost of telephone systems in Ontario are given in a recent report of the Ontario Provincial Government by Francis Dagger. This report gives the operation of the systems now operating under the Local Municipal Telephone Act of 1908.

The Act provides means whereby a municipality can furnish the necessary capital to construct a telephone system upon a petition from any number of ratepayers. This capital is repaid by the subscribers in ten annual instalments of principal and interest, the cost of operation and maintenance being also a charge upon the ratepayers who are telephone users. In this way the ratepayers who take a telephone obtain service at actual cost, while those who do not, are exempt from all liability in connection with the cost of constructing, extending, operating or maintaining the system.

The following table includes the most important farmers' telephone systems at present being operated under this Act, with the latest available figures, showing the number of subscribers to each system:

In order to convey an adequate idea of the benefits resulting to the communities in which these systems are in operation, it may be stated that in answer to the question, "How many farm telephones were there in your district before you started?" the townships of Colborne, Maidstone and Sandwich South replied "None." These three municipalities are now furnishing telephone service to 591 subscribers. In reply to the same question, the township of Colchester North replied, "One"; Gosfield, North, "Four"; Tuckersmith, "Five," and Chinguacousy, "Thirty." In these four townships there are at this date 1,296 farmers who have telephones in their homes as a result of municipal ownership under the Act referred to. It would be safe to say that similar conditions obtained in the other municipalities, although definite figures are not available.

As these figures will doubtless encourage the ratepayers in other rural municipalities to devote some thought to the important question of obtaining telephone service at cost, the writer has obtained authentic data in regard to the cost of construction and operation of these systems, of which the following is a summary:

Original Cost of System, Per Subscriber.

Brussels	$88
Tuckersmith	66
Chinguacousy	73
Maidstone	44
Rochester	41
Sandwich, South	65
Gosfield, North	43
Blyth	93
North Easthope	65
Colchester, North	40
McKillop	66
St. Vincent	57
Colborne	44
Goderich	48
Laird	38
Tay	59

It will be noticed that there is a considerable difference between the cost of constructing the various systems named. In explanation it may be stated that this is due to several causes. The Blyth system, which shows the highest cost, provided central office equipment and built pole lines to serve many more subscribers than are at present connected. The cost of connecting additional subscribers using the same switchboard and poles will be much less per telephone than $93, and in this way as the system is filled in the average cost per subscriber over the whole system will be reduced. Again, the cost of the Brussels system includes a central office building and an expensive modern central switchboard equipment; while the Tuckersmith municipality does not own any central equipment, its lines terminating upon the "Bell" switchboard at Seaforth. Chinguacousy, also, only provides a central office equipment for half its subscribers, the lines of the remainder terminating in the "Bell" exchange at Brampton. The lower cost given are mostly accounted for either by the fact that smaller poles are used, or that there are more subscribers connected on each mile of pole line. For example, in Maidstone there are five subscribers to each mile of pole line, while in Sandwich, South, there are only seven telephones for each two miles. Some systems also economize by buying lower-priced equipment, and by the farmers providing much of the labor at cost, while other municipalities purchase more expensive, because of a higher grade equipment, and had the plant constructed by qualified contractors who, of course, require a profit over and above the actual cost of labor.

Annual assessment to subscribers for ten years in repayment of cost of system, with interest at five per cent:

Brussels	$11.30
Tuckersmith	8.37
Chinguacousy	9.00
Maidstone	5.85
Rochester	5.44
Sandwich, South	8.42
Gosfield, North	5.83
Blyth	*12.00
North Easthope	*10.50
Colchester, North	5.72
McKillop	9.72
St. Vincent	7.95
Colborne	†8.00
Goderich	[illegible]
Laird	[illegible]
Tay	9.80

* Includes cost of operation.

† For five years, plus cash payment of $15.00.

Reconstruction and Renewals.—It may be pointed out that the above payments cease at the end of ten years, the original debt being wiped out. It must not, however, be understood that at the termination of this period subscribers will obtain service at the figures given in this article under the heading of "Annual Payment by Subscribers for Cost of Operation," as provision will then have to be made for such reconstruction and renewals of plant as may from time to time be rendered necessary by depreciation and obsolescence. The cost of this provision will have to be assessed against the subscribers, in addition to the amounts now paid for operation and ordinary maintenance. What the actual amount of such an assessment would be depends very much upon the quality of the equipment and the manner of its construction when the system was first built. For this reason it is important that municipal systems be well constructed and only the best equipment adopted in the first place, as a badly-constructed system, with inferior, because cheap, equipment, may require almost total replacement at the end of ten years, which would necessitate the continuance of an assessment nearly approaching the figures named above.

With a properly engineered and well built system, using high-grade equipment, a yearly amount not exceeding half the original assessment should be ample to take care of all necessary repairs and reconstruction. Assuming this to be so, in a system such as Chinguacousy, the subscribers of which now pay $9 in payment of principal and interest, plus $3 cost of operation, would at the end of ten years pay $4.50 plus $3, or $7.50 per annum, instead of $12 as at present. In considering this matter there is, however, another element to be considered, which is that the Act provides for additional subscribers paying the same assessment as the original subscribers who shared the cost of building the main pole leads and of equipping a central office to accommodate many more telephones than were installed at the start. It will be apparent that the cost of connecting additional subscribers using the same central office equipment and pole leads which have already been paid for by the original subscribers, is very much less than the amount paid by these original subscribers. This difference is set aside by the municipality as a reserve fund to be expended on maintenance, reconstruction and extensions, and it is within the range of possibility that by the end of ten years this fund may have reached a proportion which would considerably reduce the amount to be assessed against subscribers on account of depreciation or obsolescence.

municipality absolutely subject to the control of another organization. It is parallel to buying a house and giving the key to another party, with the right to control your entrance and exit according to his pleasure or goodwill towards you. It has already been argued in the law courts that a telephone system which does not own and control its central switchboard is not a system at all, but a mere collection of lines having no terminals and powerless to furnish even its own subscribers with service without the consent of another party, which it cannot control.

◆

PLACING CONCRETE WITH A MOVABLE STEEL TOWER.

An interesting method of placing concrete for a locomotive roundhouse is being used by the Lake Shore and Southern Railway in Chicago.

The chief difficulty in this particular job is the fact that concrete has to be distributed over such large area, the roundhouse being 405 feet in diameter. Also the pit walls are so high above grade that distributing by wheelbarrows is impossible and the cost of a series of wooden towers is found to be prohibitive, three towers costing nearly $2,200.

W. B. Louer, Chicago representative of Chain Belt Co., was consulted and he suggested a steel tower and from this developed the portable steel tower which has been found to be most satisfactory and economical, as the total cost set in place was less than $1,000. The material for this article has been furnished by the Chain Belt Company, of Milwaukee, Wis., while the contractor's costs have been taken from an article published recently in Engineering and Contracting.

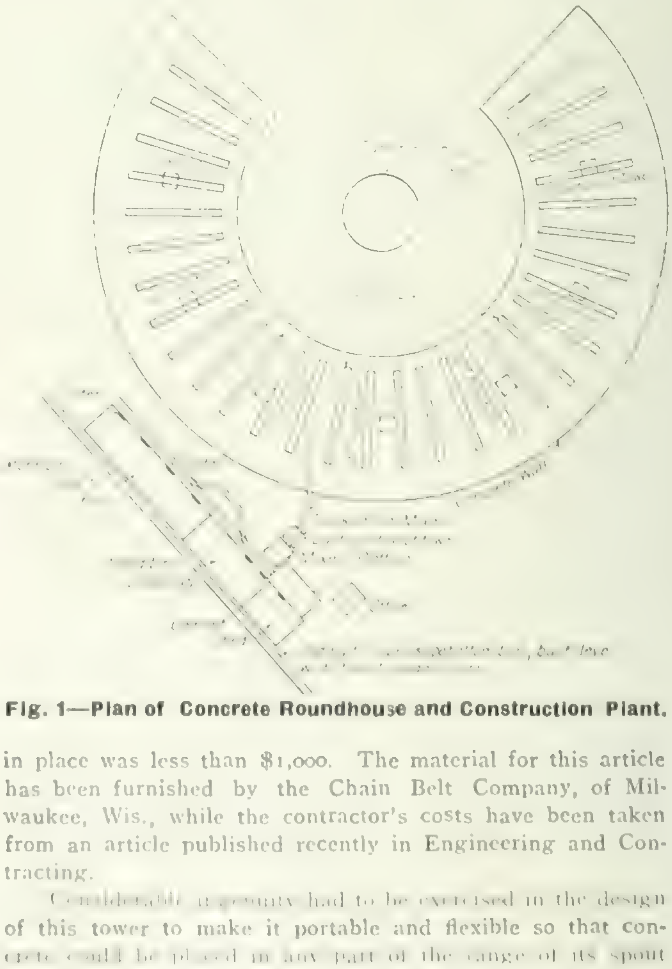

Fig. 1—Plan of Concrete Roundhouse and Construction Plant.

Considerable ingenuity had to be exercised in the design of this tower to make it portable and flexible so that concrete could be placed in any part of the range of its spout which is 60 feet long, with an additional loose vertical spout 30 feet long. This enables placing concrete 95 feet away from base of tower.

Fig. 1 shows a plan of the concrete roundhouse and the layout of the construction plant.

Fig. 2 shows the construction of the tower which is 72 feet high. The steel work is carried on wooden skids which lie across two railway rails forming a truck. On the bottoms of the skids where they rest on the rails are steel plate shoes which are fitted with clamp buts for anchoring the tower to the rails. The tower is also guyed, the guys running through blocks at the deadmen.

The horizontal spouting is made of heavy galvanized iron 10 in. by 10 in., open at the top, and is set on a light frame steel truss. The steel truss and spouts are all supported by a 40-foot boom which is rigged from top of tower and held in place by steel blocks and cable running to a winch. The winch is secured to side of tower so that the boom spout and loose leg may be raised or lowered or swung in a semi-circle, giving a wide range of work and placing coucrete anywhere within a radius of 95 feet.

The steel tower is made up of 6-foot sections, sections being composed of steel angles and channels. The tower rests on heavy wooden skids that have steel liners, which rest on railroad rails, making the whole rigging easy to move.

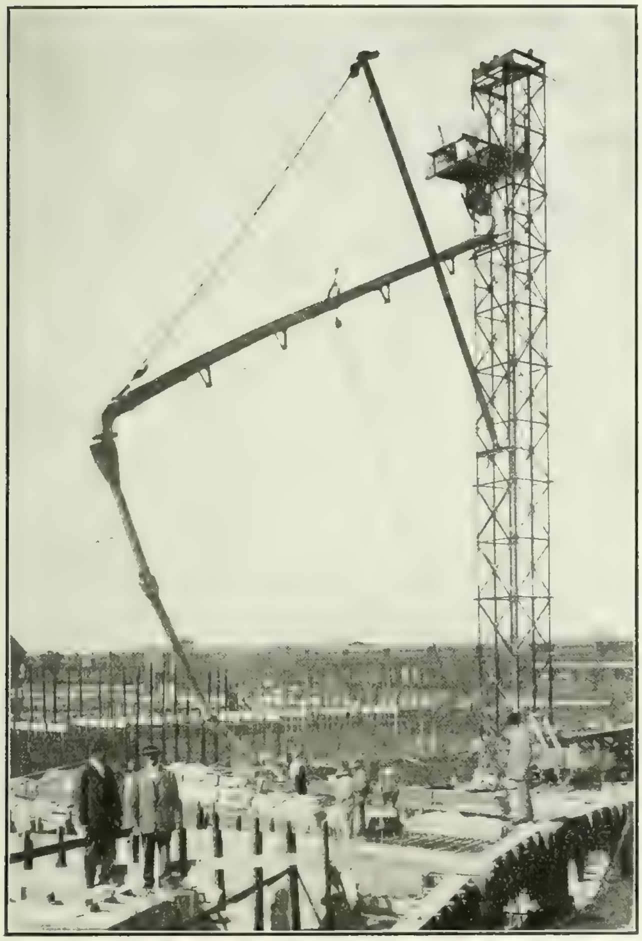

Fig. 2.—View of Steel Tower, Showing Concrete Chute in Position.

After the concrete has been placed in one section the tower is drawn back along the rails by means of the hoisting engine of the tower. This operation is accomplished by loosening the guy wires and a change of 60 feet can be made in about four hours time. Then they are ready to distribute again.

The concrete is mixed by a concrete mixer which is situated about 600 feet away from the tower on account of having the mixer near the storage bins which are on a railroad siding. The mixer discharges into cars which are conveyed to the tower, and the concrete is dumped in the bucket of the elevator and hoisted to the top of the tower where it is automatically dumped into the receiving hopper. This receiving hopper has a gate which is operated by a man standing on a platform at the top, and he regulates the flow of the concrete through the spouts.

The roundhouse is being built on a piece of ground which was formerly swampy, and the new floor will be some 5 or 6 feet above the former level of the ground. The footings for the foundations of the walls and engine pits were carried 22 feet below track grade. This work was done by hand in trenches. The work was in sand and close sheeting was necessary as was also the use of several small pumps. After the concrete was carried to ground level forms for the walls of the engine pits and for the outside walls were built. These forms carried the work several feet above the general level and the distance over which the work was spread, made the use of wheelbarrows or carts impracticable, so the chuting system was adopted. The roundhouse is about 800 feet long, measuring along the circumference. The steel tower was erected on a track running through the centre of the house and at a point within 95 feet of one end. After all the concrete up to the floor level had been placed the tower was moved back 95 feet and another set of forms was poured so that after three moves had been made, half of the concrete was poured. The tower was then "snaked" down to within 95 feet of the other end of the roundhouse and proceeded to pour the concrete there, being "snaked" backward toward the centre as the work progressed. Before the tower was moved to the last half of the work it was necessary to turn it around so that the spout would run in the opposite direction. Turning the tower about, was accomplished as follows: A pit was dug in the sand just ahead of the tower and cribbing was placed in it, with a platform and track on top so that the tower could be pulled onto it. A 40-ton hydraulic jack was arranged on the cribbing underneath so that it would operate against the platform and raise the tower about half an inch. Supported on the hydraulic jack the tower was turned around by means of a crowbar, short distances at a time, while three men at each guy line shifted them to new positions until the tower was reversed. Three men were required to a guy line as the cable and tackle block were quite heavy, and as the weight of the tower with its boom and spout is considerably unbalanced caution was exercised in shifting the guys.

The number of men required to run the plant consists of 1 foreman, 17 laborers and 2 engineers. The number may vary but this is an average crew. They are divided as follows:—

1 foreman at $4.00	$ 4.00
5 men unloading cars	16.00
3 men hauling sand and stone	9.60
1 man on cement	3.20
1 mixer engineer	6.00
1 man charging and dumping mixer	3.20
2 men on concrete car	6.40
1 man at top of tower	3.20
1 tower engineer	6.00
3 men handling spout	9.60
Total per day	$67.20

A portion of this daily cost will be eliminated for the last portion of the work when the tower will be located at the mixer. The average day's run of concrete may be taken at about 120 cu. yds. The maximum has been 147 cu. yds., but the minimum full day's run has been about 100 cu. yds. The work has been arranged so that 400 cu. yds. is run for every move of the tower. The moving of the tower requires about 4 hours, but the necessary track relaying, and the building of a new incline for carrying the concrete car high enough to dump into the hoist, requires about a day.

It may be said, then, that 400 cu. yds. is run about every 4½ days. The labor cost for this is, therefore, 4½ × $67.20 = $302.40, or 76 cents per cubic yard.

The use of the movable tower is the main feature of the concrete work, and this has no doubt saved considerable money to the contractor over the cost of handling the work by any other method.

METHODS OF ROAD CONSTRUCTION AND THE PROBLEM OF DUST SUPPRESSION.*

By Frank B. Earl.†

To the average citizen the condition of the streets seems to have been of little interest, but with the advent of motor-driven vehicles and the increased importance of highway traffic, we have come to realize that our highways are our arteries of travel and that when congestion exists the whole body of politic is made to suffer. From the moral standpoint, we have begun to recognize that, in providing a smoother path for the feet of men and by improving their method and means of communication with each other, we are making this world a better place to live in.

In conversation with the mayor of a certain city, the speaker outlined to him the general conditions of the streets as they were, suggested certain improvements, told him how the same would increase the value of the abutting property, emphasized the fact that there was no improvement possible by which the community would have both large and quick returns, that home-seekers would be attracted, rentals increased, etc. As a result the Mayor expressed a desire that the [illegible] as well as the community at large, with the [illegible] result that a public meeting was held and a general outline of the above suggested benefits given to the public. This is a long step in the right direction, as it is the taxpayer who is most vitally interested in these questions, because he is the one who foots the bill.

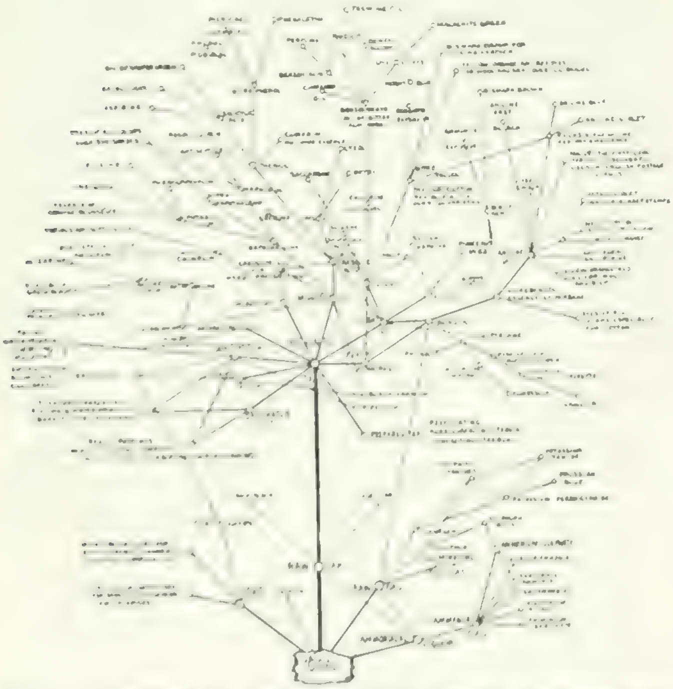

Fig. 1.—Products of Coal Tar, with Special Reference to American Conditions.

[illegible]

There was spent on the roads in the United States last year $142,000,000 and I presume that nearly twice that amount will be spent during this coming year. New York State is bonding for $50,000,000; Ohio is likewise bonding for $50,000,000, and Pennsylvania for the same amount; New Jersey $10,000,000, and thus it is being done all over the country.

In Montclair, N.J., they are considering the advisability of issuing bonds to the amount of $400,000 to make it "The Town Beautiful." Essex County, N.J., has increased its appropriation for repairs $30,000. The city of Newark, N.J., is spending nearly $1,000,000 more this year than it has ever expended before.

This gives some idea of the amount of money appropriated, and shows why the attention of legitimate business has been attracted, and it also provides a reason for the large number of questionable enterprises which come and, fortunately, go with the season. Some of the difficulties arising from these conditions are startling, and at times contracts seem to have been let, because of the low prices offered, to irresponsible bidders who, of necessity, were compelled to resort to dishonest practice or lose money on the job. The speaker believes the time has come when contractors will form some sort of combination themselves and seek to classify business interests—a step which would doubtless result in multiplied benefits to all concerned, and which is, he believes, within the scope of this society.

The speaker considers it a privilege to talk with the members of this society regarding come of the problems of road construction which we all meet every day, and about which little or nothing new has been advanced within the last year. For that reason it is a subject about which he always feels a sense of embarrassment when asked to speak. He does not know that he has anything new to present, but such as he has he will gladly share with you.

The ordinary water-bound macadam roadway when subjected to automobile traffic rapidly goes to ruin and for some years past many experiments have been made to replace this type of construction by substituting some more effective binder, both on new work and the resurfacing of old roads; the two chief binding materials experimented with being asphaltic and tar compounds.

Both asphalt and tar are used in new construction and in dust prevention—there being many grades of each, varying in density and viscosity, the lighter grades being used for dust prevention and the heavier in resurfacing and new construction.

Naturally, the speaker is best acquainted with Tarvia, because he deals in this material exclusively in the construction of roads and for the prevention of dust. In his experiences with various municipalities over a part of two States and in driving constantly over the roads, he comes in contact with every form of material that is on the market and has opportunity to note the method, results and machinery, and to draw definite and intelligent conclusions, which he will endeavor to state briefly to you without any disposition to criticize one way or the other.

In order to present the pedigree, so to speak, of the tar binder, he is forced to start at the real beginning of affairs—for you all know that tar is a derivative of the distillation of coal and that coal itself was formed in the Carboniferous Age by the accumulation of masses of vegetation and trees.

Very little is at present known about coal. Some writer has aptly called it "buried sunshine." Not a misnomer, as it suggests the source of light and heat which is driven off from the coal and also the diversified colors which we get from the coal tar products. During this formative period of coal these forests were the habitation and feeding place of the Brontosaurus and other Saurians that have been extinct for ages, but the skeletons of which have been found in the rocks of that period by modern scientists, carefully chipped out, and assembled into the complete skeleton. The larger museums contain specimens of these animals—the American Museum of Natural History in New York City being especially favored in that respect.

---

* Abstract of paper presented at meeting of the American Society of Engineering Contractors, May 8th, 1912.

† Assistant manager and salesman, "Tarvia" Department, Barrett Mfg. Co., 17 Battery Place, New York City.

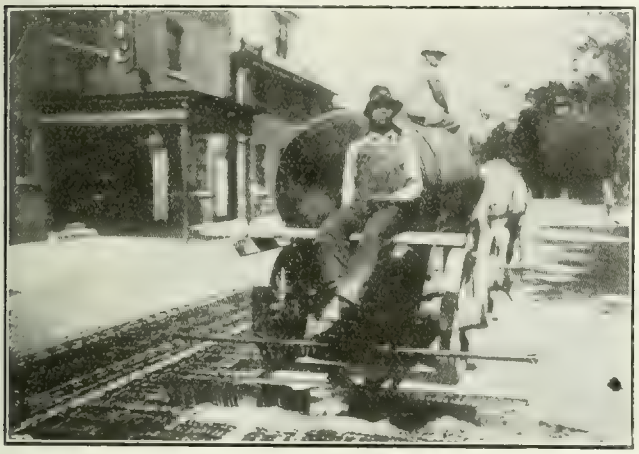

Fig. 2.—Distributing Tarvia "B" by Means of an Ordinary Watering Cart Fitted with a Distributing Device.

The family relation existing between coal and tar and the derivatives is graphically shown in the coal tar tree. (Fig. 1). The main stem of this represents the raw tar. Off to the left coke is designated, which is a residue from the fractional distillation of coal. The drawing also shows the production of gas and ammoniacal liquors, refined tars which are used in the saturation of felt for roofing and waterproofing purposes, and those which are manufactured into Tarvia for use in road construction. You will also notice that the various branches of this tree represent the drugs, chemicals, disinfectants, germicides, insecticides, and almost innumerable by-products. Finally, it is of interest to note that by synthetic chemistry we have a class of coloring dyes, etc., which are important in the commercial world.

The making of coke and the separation of the distillates was formerly accomplished by the Bee-hive oven, patented in England in the year 1620. The coal is fed into the oven through the opening at the top and leveled off with a hand rake. The face of the oven is then bricked up to within a few inches of the top, and the heat, which has been retained in the brick from a previous operation or from a preliminary heating, is reflected from the dome of the oven, thereby causing the coal to disintegrate. The gases pass out through the opening at the top, leaving a residue which hardens upon cooling. This is of a light silvery color, and is known as "Coke." In this type of oven all of the by-products are lost, and because of the smoke and disagreeable odors of escaping gas it was impossible to operate it in the near vicinity of dwellings. For these reasons the Bee-hive oven is rapidly becoming replaced by the more modern coal gas retort. In this the operation is substantially the same, except that the distillation of the bituminous coal is done under the exclusion of air. By this method the gases are carried off in pipes, recondensed and scrubbed, thus relieving them of their deposit of tar and ammonia.

The modern gas retort is a more efficient type of oven, which, being built in series, is capable of handling a much larger quantity of coal, and as it is mechanically operated, is much more economical. In the treatment of the gases for the recovery of the tar and ammoniacal liquors, the gas is forced through a series of baffling plates which are perforated with tiny holes. The plates are placed one back of the other, but in such a way that the unperforated surface of one plate is opposite the perforation in the other plate. The gas is then drawn through these plates and the tar, which exists in minute globules, adheres to the unperforated surface of the plate and is thus recovered. For the recovery of ammonia the gas is passed through a cylinder containing revolving wooden paddles which are constantly kept wet, and the gas coming in contact with the wetted wood is relieved of its ammoniacal deposit.

As it has been shown, in a general way, how tar is produced, it might be interesting to explain the manner of its distribution to consumers. It is sent in tank cars, which are fitted with steam coils to heat the material before transferring it to the distributing wagon. It is also shipped in barrels by rail or boat and by tank steamers, the hold of which is partitioned off fore and aft for the transportation of tar in bulk.

There are three grades of Tarvia on the market—"A," "X," and "B"—the "A" and "X" grades being used in new construction and resurfacing, while the "B" grade in light resurfacing, and as a dust preventative. For example, Tarvia "B" was successfully applied to the surface of a water-bound macadam street in Phillipsburg, N.J.

In this instance an ordinary watering cart was used, fitted with a distributing device, as seen in Fig. 2, at a cost of about $10. The surface of the street was first carefully swept, then from one-third to one-half gallon of Tarvia "B" was evenly distributed over the surface and broomed out with hand brooms where necessary. After an exposure of several hours this surface was lightly covered with a drifting of sharp, clean sand and the street thrown open to traffic. The initial cost of this treatment was 3 7/10 cents per square yard. The traffic there is more than ordinarily heavy, the street being the outlet for several foundries. Notwithstanding this, the street has been maintained for two years without other maintenance than the annual application of Tarvia "B."

Fig. 3.—Rolling a Tarviated Macadam Road Constructed by the Mixing Method.

In new construction there are two distinct methods of application—the penetration method and the mixing method. In the former the tar binder is applied by hand or machine to the stone in place on the road, while in the latter the stone and binder are mixed together, like concrete, and then the mass deposited and the road rolled. (See Fig. 3).

Early Street, Morristown, N.J., is an example of the penetration method of construction of a 6-inch tarviated macadam in which Tarvia "X" was used as a binder. The method employed in the construction of this street was as follows: First, the road bed was carefully prepared, and, after being brought to grade, thoroughly rolled. Four inches of crushed stone of the 1½-inch size was then placed upon the road and likewise rolled until there was no perceptible movement beneath the roller. Over this was placed two inches more of the same size stone, and these again rolled. Tarvia "X" to the amount of one and one-half gallon to the square yard, heated to a temperature of 250 degrees Fahr., was then poured by hand from suitable sprinkling cans upon this prepared surface, after which clean screenings were drifted over the surface of the road in sufficient quantity to fill the voids without leaving any excess material. The road was then again thoroughly rolled and the second coat of Tarvia "X," from one-half to three-quarters of a gallon per square yard, poured over the surface. Over this finally was placed another coating of screenings and the road thoroughly rolled to a finish.

The entire cost of laying this pavement, including all the gradings, was 78 cents per square yard. Early Street was paved two years ago and is at present in good condition.

In passing it may be of interest to note that the cost of removing Tarvia from the package and heating it to the required temperature is about one and three-fourth cents per gallon less than the cost of the same operation with asphalt binders.

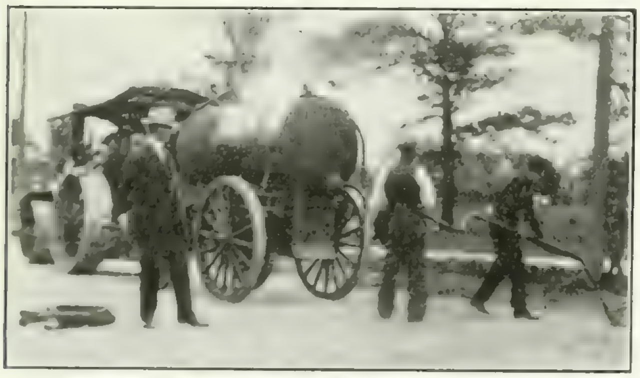

Fig. 4.—Tarvia "X" Being Distributed from a Tank Wagon Fitted with a Fire Box and Hose Attachment.

Tarvia "X" can be quite readily transferred from the barrel when one head is removed, and if reasonable care is exercised it is not necessary to destroy the barrel.

The distribution of Tarvia "X" from a tank wagon fitted with a fire box by means of a hose attachment is shown in Fig. 4. In this operation the Tarvia is heated in the tank car, drawn off into the tank wagon, which has a capacity of [illegible] gallons, attached to the steam roller and drawn to the point of operation. Steam connection is made between the roller and the tank wagon and the Tarvia forced from the tank through the hose under a pressure of about 15 pounds. This method is recommended as being more efficient and economical than the use of hand distributors.

The mixing method [illegible] is favored by many [illegible] than the penetration method. The materials are either mixed together by hand or by machine. In the case of hand-mixing, Tarvia "X" heated to 250 degrees Fahr., using from [illegible] gallons to the cubic yard of stone, is thoroughly mixed by hand upon a mixing board and placed upon the prepared road bed to the required thickness. The mixture is then leveled off with hand rakes, the voids filled with screenings, and the whole thoroughly rolled. Over this again is poured, as in the previous operation, the required amount of Tarvia. The second coat of screenings is then applied and the road rolled to a finish.

The method employed in machine-mixing was used recently in the construction of Park Avenue, Newark, N.J., which was built by the Essex County Park Commission. Crushed stone is loaded into the hopper, which is then lifted to an elevated position and its contents delivered into the drum of the mixer, where it is heated. After the stone is thoroughly dried and heated to the desired temperature, Tarvia "X," which has been previously heated in an ordinary heating tank, is also mechanically lifted and deposited upon the stone in the mixer. The stone is then thoroughly coated with the Tarvia, after which it is dumped into wheel-barrows and carried to its destination. The evidences are that this is destined to become a very popular method for the construction of bituminous macadam roads, and the experiences of those who are familiar with this machine would lead us to believe that it is well adapted to this work.

The asphalt bound macadam is built by using these same methods of construction (with the exception that heavy asphalt is used instead of tar as a binder). Many types of new roads have been experimented with during the last few years—with the view of solving the problem of an automobile-proof road without going to the heavy expense of a permanent pavement. One of the latest additions to the list is known as "Dolarway Pavement." This consists of a carefully laid concrete base, usually six inches thick, of not less than 1:3:5 mix, with expansion joints approximately every 25 feet. Upon this prepared concrete base there is placed a thin coat of Dolarway bitumen which is broomed out with a horse sweeper. This method of construction has been thoroughly tried for several years, and the evidences are that in the near future it will become very popular. This pavement is low in the first cost, dustless, resilient, economical to maintain, and, in fact, has all of the virtues of the best types of permanent pavements in use to-day without any of their disadvantages.

◆

TESTS OF CROSS-ARMS.

The Department of Agriculture, Forest Service, has recently been conducting some strength tests of cross-arms and results are embodied in Circular 204, just issued by the department. The material tested includes practically twelve cross-arms of each of the following seven groups: Douglas fir, shortleaf pine, longleaf pine, graded by the manufacturers as 50 per cent. heart; longleaf pine, 75 per cent. heart; longleaf pine, 100 per cent. heart; Southern white cedar, and shortleaf pine, creosoted. Each of these cross-arms was tested in a 200,000-lb. Richle universal testing machine. The comparative strength was as follows:

	Average Maximum Load.
Longleaf pine, "75 per cent. heart"	10,180
Longleaf pine, "100 per cent. heart"	9,780
Shortleaf pine	9,260
Longleaf pine, "50 per cent. heart"	8,080
Shortleaf pine, creosoted	7,650
Douglas fir	7,500
White cedar	5,200

A summary in the report concludes with the statement that, all things considered, cross-arms of the species and dimensions tested are strong enough for ordinary use; with longer arms the strength is relatively of much more importance. With the standard cross-arm, however, the question of strength need not enter into calculations of line construction, except in the rare case of abrupt change in grade. The ability of the timber to resist decay and methods of preventing decay are considerations of greater importance.

CONCERNING WEB STIFFENERS.

It is easy to say that the function of a stiffener is to prevent buckling of a plate girder web, and that it must be designed to accomplish this purpose. But when one attempts to summarize one's ideas as to how this shall be done one finds that the fund of accurate information concerning stiffeners is meagre. The actual design is accompanied by so many assumptions as to make one who inclines to theory rather than experiment somewhat sceptical of the results obtained. Notwithstanding the indeterminate character of the action of stiffeners of loaded plate girders, it is satisfying to know that failures of web stiffeners are very rare, and that those that have been known to occur are of such a nature as to cause no other serious consequence than slight inconvenience and expense of repairs. But many tons of steel are used annually in stiffeners, and the subject is therefore one that merits more study than has been given it, says the "Engineering Record."

Web stiffeners are used at concentrated loads for the double purpose of transferring these loads from the flanges into the web and to prevent the web from buckling under the compression, and they are also used at intermediate points between concentrated loads solely to prevent buckling of the web. The sizes of these intermediate stiffeners are nearly always assumed, but their spacing—that is, the horizontal distance from one set to the next—is now quite generally determined by a formula based upon compression in the web. resulting from the shearing forces acting upon it. Some important specifications still use the arbitrary method of spacing intermediate stiffeners at horizontal distances not exceeding the depth of the girder, even though this rule has practically no reason for its existence. Since the tendency of a web to buckle must be due to the compression acting within it, and since this compression is a direct function of the shearing force on the web, it seems perfectly clear that the method used for spacing intermediate stiffeners should bear some relation to that shear; that, other things remaining the same, the greater the shear the closer together should be the stiffeners.

There seems to be a deep-seated conviction that intermediate stiffeners must be fitted accurately at both top and bottom flanges, for by being so arranged they add strength to the girder in some mysterious way. It is readily seen that if fitted to a compression flange, stiffeners might act to a limited extent as braces to this flange, and hence the expense of fitting them might be justifiable; but when one looks for a reason for fitting them to a tension flange it is not forthcoming, except it be in the desire to secure a tight fit for the sake of appearance, or to eliminate small openings wherein painting is difficult. Of course, it is perfectly right to insist on close fitting at flanges for either of these two reasons, but let us not deceive ourselves into thinking that intermediate stiffeners must be fitted to both flanges to add strength in some unknown manner.

Stiffeners at such concentrated loads as bearings and columns should be, and usually are, designed as columns, and sufficient rivets should be placed in them to transmit the proper forces between stiffeners and webs. Determining the cross-sectional area of a set of stiffeners under a column load or over an end bearing by applying the ordinary column formula is on the side of safety, for this process assumes the stiffeners to have their maximum compression throughout their entire length, whereas the stress diminishes from the maximum at one end to zero at the other. In this respect, therefore, the ordinary stiffener at a concentrated load differs from a column, because in the latter the loads are applied at the ends, and column formulæ as generally used apply to this case only.

Consider the stiffeners under a column which rests upon the top flange of a plate girder. The entire column load is transmitted first to the top flange, then to the outstanding legs of the stiffeners under the column. The outstanding legs must be carefully fitted, and must be of sufficient area to give proper bearing against the horizontal legs of the top flange angles. The stiffener legs lying against the web transmit very little or no stress from the top flange, because they are sheared or ground to fit the curved fillet of the flange angles, and should be neglected in determining the required area for bearing at the top flange, and it is for this reason that only the outstanding legs of stiffeners should be relied upon to transmit the column load from the inside of the top flange angles. When the stress has thus entered the outstanding legs, these legs are thrown into compression, and until a portion of this stress is transferred to the legs lying against the web, the comparatively thin projecting legs must be able to sustain this comparative stress without buckling.

It is just here that a link in the chain is usually overlooked, for this buckling tendency is ordinarily not considered, even though the bearing against the flange may be carefully provided for. As the stress becomes distributed over both legs of the angle stiffener, column action is approached, and for this reason a column formula is applied to determine the gross cross-sectional area of the two legs of the stiffener. In the case here supposed—that is, the case of a stiffener under a column,—the maximum stress exists only for a short distance down from the top, for the uppermost rivet in the stiffener transmits its quota of stress from the stiffener into the web, and each succeeding rivet further diminishes the stress until at the bottom the stiffener has no stress at all. Consequently, when stiffeners are designed as columns having the full stress through a length equal to the girder depth, they are on the side of safety.

It is apparent, then, that if the bearing of the outstanding legs be sufficient to transfer the column load from the top flange, that if the cross-sectional area of the stiffener angles be large enough to satisfy the column formula, and that if the rivets be the correct number, there still may be a weak link in the design if the buckling of the outstanding leg at the top be overlooked. An interesting case of this buckling occurred a few years ago at the Union Street drawbridge in Salem, Mass., U.S.A., This was a deck plate girder highway swing bridge, with a centre bearing having the entire revolving weight suspended from the centre casting by means of a series of round rods which were attached at their ends to the top of the centre casting. The rods passed through holes in the distributing girder flanges, and their lower ends engaged in nuts bearing against the bottom flanges of the distributing girders. This arrangement resulted in a series of large concentrated upward forces on these flanges, and a set of angle stiffeners were used for reinforcement at each rod. The outstanding legs of these stiffeners were too thin. and they buckled, the buckling being confined to the lower 8in. of each stiffener. As a consequence of the failure of these stiffeners, the drawbridge settled vertically to such an extent that its operation was almost impossible because of frictional resistances at the abutments. The Salem case made an everlasting impression on the engineers who had anything to do with it, for local column action of the outstanding legs had been manifestly overlooked in the design.

The brief analysis here given indicates that the designers should investigate four things in connection with stiffeners at a concentrated load:—

First, the bearing area of the outstanding legs should be sufficient to transmit the column load from the flange.

Second, the thickness of the outstanding leg should be sufficient to prevent buckling of this leg.

Third, the entire cross-sectional area of the angle or angles should be sufficient to carry the load as a column having a length equal to the depth of girder.

Fourth, enough rivets must be placed in these stiffeners to transmit their stress into the web.

The action of stiffeners over an end bearing of a girder is similar to the case here considered, unless there be on top of the girder a column load. In the latter case the stiffeners must not only transmit the shear from the web into the end bearing, but they must also carry the column load from the top flange of the girder to the bearing. While the principles involved in the two examples are the same, their application is slightly different.

A NEW AUSTRALIAN DAM.

The cabled announcement of the formal opening of the Burrinjuck Dam in New South Wales, and the irrigation scheme for which it is to supply the water, is a more than ordinarily interesting event in Australia's domestic history. Burrinjuck is not as large as Assuan Dam, but it is the second largest dam in the world, and it certainly rivals the great Egyptian work in picturesqueness. It is set in between two steep granite hills that rise from oposite sides of the Murrumbidgee River. These mountains are about 2,500 feet high and form the gateway to the long and winding gorge, rugged and rocky, through which the upper Murrumbidgee flows for about 200 miles.

The dam, set in the neck of the gorge, will ultimately rise to a height of 240 feet from the foundation level—ultimately, for the engineers have decided that the irrigation scheme can be started with the dam at only about half the height it will have reached when the entire area is ready to be watered. The areas immediately adjacent to the Yanco diversion channel can easily be served with the dam at a height of only 120 feet, and this land is the portion now formally opened. The dam is expected to reach its full height some time next year. The retaining wall will then be 240 feet high, 784 feet long (curved in plan to a radius of 1,200 feet), with a breadth of 170 feet at the base and 18 feet at the crest. It will back up the waters of the Murrumbidgee for 45 miles in the long gorge, and create an inland sea among the mountains of 20 square miles in area and over 33,000 million cubic feet in content—nearly half as big again, say the mathematicians, as Sydney Harbor. It is calculated that on the average flow the Murrumbidgee will take a year to fill the Burrinjuck reservoir.

From Burrinjuck the water is, under regulation, allowed [illegible] to Berembed Weir, near the town of Narrandera. From Berembed the diversion canals reach out. The Berembed Weir and lock have [illegible] a main diversion canal, now nearly completed to its full length, runs out straight in a north-westerly direction for 132 miles to [illegible] rivers and the canal is to receive particular attention from the irrigationists, but subsidiary channels stretch out to the east [illegible] and, finally, when the northern irrigation scheme is in full [illegible]

THE ATTITUDE OF THE RAILWAYS TOWARD FOREST FIRES.*

E. A. Sterling, F.E., Forester, Pennsylvania Railroad Company.

"Railroads" and "unknown origin" are the two headings under which the causes of a large majority of our forest fires are listed. Even after allowing for inaccuracies in the records, the number of fires resulting from railroad locomotives is unquestionably large. The attitude of the railroads towards the forest fire evil, and the possibilities of reducing this particular source of danger, are therefore questions of interest and importance.

While the railroads for many years have, perhaps, shown too little interest in forest protection, it must be remembered that indifference has characterized most of the other interests, from the Government down to the smallest woodlot owner. The railroads could hardly be expected to worry about forest fires when the States through which they ran had neither laws nor organization to prevent or fight fires. So many of the developments tending toward the solution of forest problems have not taken place until recently, that criticism of any particular interest reflects discredit on all. Practically all of the definite accomplishments in forestry, both in Canada and the United States, have taken place in the last ten years, and the greatest achievements are less than five years old.

Under the latter, the beginning of effective fire protection stands out prominently. Our forests are still far from safe, but Federal, State, and private activity has paved the way, and another decade should remove the fire menace from our remaining forests. In this work, which must be co-operative to succeed, the railroads are doing their full share.

Certain basic causes must underlie any given set of conditions. If the railroads have been the too frequent cause of forest fires, there are various reasons why this has been true. First of all, no spark arresters have been designed which will eliminate flying sparks under all conditions, and at the same time give the locomotive free draft. While the various devices in general use greatly reduce the danger from this source, the fact must be accepted that there are certain mechanical difficulties which have not been entirely overcome.

If it is recognized that sparks capable of starting fire reach the ground, the next logical step would be the removal of inflammable material from the right-of-way. It is easy to advise this, or even to legislate to this end; but to the comparatively new roads which have pushed into the forest regions, the expense of a fireproof right-of-way is a very serious consideration. Most of the main trunk lines now clear their right-of-way twice a year, but this is by no means a guarantee against fires from locomotive sparks. The strip of property owned by the railroads is too narrow for a safe fire belt. Adjoining property offers quite as great a menace, so that, even if the railroads kept a right-of-way of fresh mineral soil, live sparks might easily start fires in the slashings and accumulated litter on adjoining property over which they have no control.

A[illegible] other consideration it may be mentioned that [illegible] the railroads shared in common with the public the attitude of calm indifference as to what happened to our forests. Corporations occasionally lead in developing public sentiment; more frequently they are guided by it. The man [illegible] is hardly awake to the importance of forest protection, [illegible] the railroads are taking the matter [illegible] in advance of public sentiment.

---

*Paper read before Canadian Forestry Association, February [illegible]th and [illegible]th, [illegible]

The fair analysis of the situation reveals several reasons why the railroads have been either the primary or the indirect cause of many forest fires. No reasons can be found, however, for the railroads deliberately,permitting or desiring to start fires, although such is often the popular conception of the matter. From many standpoints the railroads are the heaviest losers when a forest area burns. It takes away tonnage, both present and future; reduces summer tourist travel; and, unless the region is developed for agriculture, merely furnishes ground on which to run tracks between more productive points. Damage claims follow every fire, and alone are enough to bring about any protective measures within reason.

The past gives us little of which to be proud, so it is best to forget, save as a lesson, the semi-annual pall of smoke which has marked our forest fire losses. If we date our history some two or three years back, we can find basis for a future of greater promise. In the United States, no one factor in forest fire prevention can be mentioned without including others. The Forest Service set the pace in the systematized fire work on the national forests; while the States, the timberland owners, through their forest protective associations, and the railroads followed. To-day all are working together in closer co-operation than was ever believed possible, and the results from only two years of combined efforts are most encouraging.

To tell specifically what the railroads are doing would occupy too much time. Briefly, the measures which are proving most effective are the removal of combustible material from the right-of-way, systematic reporting of all fires which start, and prompt action in extinguishing them, regular patrol during dry seasons, use of oil-burning engines in forest regions, wherever practicable, and the keeping of spark arresters and ashpans in good condition. The clearing of land adjacent to the right-of-way is a very important development, which is permitted in Massachusetts and required by New Jersey, the latter providing for a 200-foot strip between the outer rail and a 10-foot fire-break. About 235 miles of such fire-breaks have been constructed during the past two years, with the result that the number of fires has been very greatly decreased. Where the Northern Pacific and Great Northern Railroads traverse National Forest land, 200-foot strips are cleared and maintained under a co-operative agreement between the railroads and the Forest Service.

The systematic patrol of the railroads, particularly under the direction of the State forest officials, is proving a valuable fire preventive measure. Minnesota provides for this in the new forest law; New York has required the patrol of railroads in the Adirondack region; while the Maine Central has provided a voluntary patrol. In the West, the Forest Service co-operated with the railroads in patrol work, most of the patrolmen being on the Government rolls, because of the protection afforded adjacent forest land.

The use of oil-burning engines is required by law in New York State from April to November on all roads traversing the Adirondack forests. This, however, puts a heavy burden on the railroads, and is hardly a fair or practical measure in regions remote from sources of crude oil supply. Two transcontinental roads, after extensive experiments, have voluntarily installed oil-burning engines on divisions traversing the National Forests.

The Pennsylvania Railroad and other roads operating in the more thickly populated Eastern States have to contend mainly with small fires started in woodlots, stubble fields and second-growth woodlands. These fires rarely assume serious proportions, and are guarded against by the trackmen and other employees, all of whom are under definite instructions to report fires and promptly extinguish those which start. Only one fire was reported by the State fire wardens as having been caused by the Pennsylvania Railroad during 1911, and this, upon investigation, was found to have occurred beyond the possible range of live sparks.

A striking summary of the railroad forest fire problem and most excellent recommendations for fire control were passed as resolutions at the Forest Fire Conference in Portland, Oregon, in December, 1911. It would be impossible to do better than close by quoting these resolutions:—

Whereas, The protection of the timber resources means: The stumpage value to the timber owner of approximately $2 per M. feet B.M., employment and remuneration to the wage earner of approximately $8, tonnage to the railroads both in supplies, equipment, and forest products approximately $6 to $8 per thousand, benefits to the farmer and merchant through the use of supplies, an insurance of community prosperity and the general public welfare; and,

Whereas, It is recognized that the railroads operating in forested regions are a source of fire danger menacing the preservation of this resource for use; and,

Whereas, The danger from forest fires is common to all and co-operation is necessary to meet this danger; now, therefore,

Be it resolved, That in order to secure the best results this co-operation be systematized along the following lines:—

1. Clearing up rights-of-way of railroads of all combustible material on ground; not necessary to take down trees or take out stumps unless punky, rotten or hollow.
2. Establishing efficient patrol of tracks during dry seasons, both night and day.
3. Increase efficiency of spark arresters and transforming of all engines being operated through timbered districts to oil-burners as far as practicable.
4. More strict enforcements of orders that steam be turned on all ashes dumped from engines. Stringent enforcement of orders that no ash-pans be dumped while train is in motion.
5. That orders be given expediting the furnishing of men from road gangs and section crews.
6. Reports of all fires by all train crews at first telegraph or telephone station.
7. Sharing expense of patrol by railroads.
8. That association, Federal and State organizations furnish their regular employees within their respective territories to assist in fire patrol.
9. That authentic information of the condition of railroad rights-of-way, the methods used under different conditions, and of all fires originating on or adjacent to the right-of-way be obtained by Federal, State, and private organizations in order to present definite data to effect improvement in methods.
10. That this situation be kept before the railroads, the organizations interested in fire protection, and the general public, in order to ensure a practical working out of these recommendations.

I have been asked to say a word in addition as to what the Pennsylvania Railroad is doing in relation to forestry The main line of the Pennsylvania Railroad runs through a hardwood country, mostly second-growth hardwood, where the lumbermen, in the early days, took off most of the valuable timber. The railroad has some thirty thousand acres on which a start has been made in exploiting the timber on a commercial basis. Work has been done on some fifteen properties, and after our logging operations these properties are in a much more productive state than before. The work has been done on a much more economical basis than by lumber companies in Pennsylvania, and the net profits have been approximately $10 per acre. This has been done by finding a market for the products that the lumbermen are unable to sell.

On the technical end we were very careful to cut with reference to a future crop. We found a market for everything produced, and I think the forest has been left in as good shape as is possible in view of the timber being taken off. Utilization has been carried to the finest point, practically everything, even down to the charcoal wood, being cleaned up. We have revived the charcoal industry, and are burning charcoal on old hearths that were abandoned so long ago that six to eight-inch trees are growing up through the centre of them. The question of forest utilization is closely allied with the water supply problem. Therefore, we have had to modify some of the cutting in reference to the water-supply end of the question.

In planting and nursery work, the policy is to plant about a million trees a year. We do not always reach that, and I am not sure that it is advisable. It is a question as to how extensively a corporation should engage in forest planting. This is not what I would be expected to say, perhaps, but I believe that for most Eastern railroads the purchase and long-time management of timber lands is more profitable than planting. Forest planting, from a general standpoint, is very important. The road is trying to teach the farmers to plant waste lands, and also how to handle their wood lots. This coming spring seedlings are to be offered from the company's nursery at practically cost price. How great the demand will be I do not know, for there has not been very much enthusiasm about forest planting because there has been so much second-growth forest land.

Another point is that of fire protection. On the properties which are being logged and planted we have done the usual things in the way of fire protection, with which you are familiar. General instructions have been issued to all trainmen with regard to fire. Recently these instructions were summarized and distributed in booklet and placard form to employees, and also to the farmers along the line. I think the people are pretty well aware that fires are something we do not want.

As to preservative treatment of timber against decay, I think that is more important than planting; I do not know that it is more important than lumbering. It means a good deal in a hardwood country like Pennsylvania, because we have non-durable woods, such as beech, birch and maple, which are now being converted into ties. When these woods are treated with creosote they give better life than the durable and more expensive species, such as white oak, which are used untreated. The railroad treats the equivalent of a million and a half ties a year. By treatment these million and a half ties will last three times as long as they otherwise would, and practically cut down the drain on our local forests to that extent. The railroads, however, are not in the treating business for the purpose of helping the forests, but to save money. Still, wood preservation, in my opinion, is an important factor in the line of forest conservation.

All these specific things the Pennsylvania Railroad and other railroads are doing; but with the exception of the [illegible] Railroad, so far as I know, they are not tackling the major problem, which is that of timber supply. The railroads are continuing their consumption of timber every year, but they are not [illegible] a thing to provide for their demands ten or fifteen years hence. The [illegible] Railroad [illegible] and it has bought land in the South with a view to [illegible] a supply for both the present and the future.

[illegible] the railroads and other large wood-consuming corporations [illegible] It certainly [illegible] of their [illegible] wood [illegible] The planting of trees will not of itself meet the problems for each corporation. We could plant ten million trees a year, but that would not save the day, because the trees would not mature in time. And, what is more important, it will cost more to buy open or cut-over lands locally and plant them than to go into the South and buy mature timber. That can be proven by figures.

It seems to me that the logical thing, the step that will make forestry permanent, is for the consumer to get into the timber-producing business. But this has not been done. It seems to me that one reason for the present do-nothing policy is that the higher officials, the men who really run the railroads and control the finances, are enthusiasts along other lines than that of wood-production. They do not see why they cannot buy ties just as they buy rubber bands. They have been told that difficulties would come, but an idea like that does not sink deep into minds which have developed with other ideas. Other interests, other problems, other policies command attention, and it is a hard job to make these people see that they are going to find they will be in difficulties for wood. Yellow pine ties have increased in price at the rate of three cents per tie per annum, but that does not necessarily mean anything to a purchasing agent, general manager, or president. The fact that tie renewals will cost a few hundred thousand dollars more a year is not overshadowing in importance; it will simply be made upon something else. But this problem may come with a rush. I hope it does, because I believe it will be the greatest thing for forestry that ever happened. The steel tie may come, but that is really not part of the problem.

I merely wish to call your attention to the big wood supply problem that the railroads are facing. They are doing their share along the ordinary lines of fire protection, planting, wood preservation, etc., but the other things, the big problems of wood supply for the consumers of the future, remain unsolved.

◆

THE CASTING OF A LARGE BED-PLATE.

The Mesta Machine Company, Pittsburg (U.S.A.), recently cast an engine bed, the net weight of which was 120 tons. The casting is one of the bed-plates for an engine that is being built by the Mesta Machine Company, and which will be installed by the Youngstown Sheet and Tube Company, Youngstown, for operating its blooming mill. As 130 tons of metal were required to pour the mould, the iron was tapped simultaneously from five air furnaces, each furnace having been charged with iron of the same average analysis. The melting of the metal was so regulated that all of the furnaces were ready to tap at approximately the same time. The metal was tapped into six ladles, four of which were poured at one time, and, after these were emptied, the contents of the remaining two ladles were poured into the mould. Binders were placed across the mould throughout its entire length, and these were held in position by rods extending through the bottom plate. Bottom-pouring ladles were used, such as are generally employed for casting steel. This large mould was poured in an exceedingly short period, as only [illegible] minutes elapsed from the time when the metal was tapped into the ladles until the mould was filled. The casting was allowed to cool slowly in the sand for a period of 16 days. The removal of this casting from the pit presented an interesting problem, owing to its great weight, which, including the cores, must have approximated more than [illegible] tons. The sand was first removed from around the sides of the casting, and each end was gradually raised until the entire casting was clear of the pit. This permitted the removal of the cores and facilitated the subsequent handling of the bed-plate.

THE STRENGTH OF CONCRETE POLES.

Tests on reinforced concrete poles were recently conducted by the Carnegie Steel Company at its plant in South Sharon, Pa., with the view of determining the relative cost and strength of that material as compared with wood for such construction. The poles tested were 32 ft. long, 10 in. square at the butt and 6 in. square at the top. All corners were bevelled and iron steps bent up ¾ in. were inserted in the forms before placing the concrete. The mixture used was 1 part of Universal Portland cement, 2 parts bank sand, passing ¼-in. screen, and 4 parts crushed limestone, passing a ¾-in., but retained on a ¼-in. screen. About one barrell of cement, ¼ yd. of sand and ½ yd. stone were used in the construction of each pole.

The reinforcement consisted of four groups of twisted rods at the corners placed not less than ¾ in. from the surface. Each group was made up of one ½-in. rod 32 ft. long, two ½-in. rods 24 ft. long and 3/16-in. rods 16 ft. long. The reinforcement was thus proportioned to the decreasing stress toward the top of the pole. Sheet steel separators held the reinforcement in place and were cut away to avoid breaking the continuity of the concrete above and below the separator.

The forms used consisted of an upper and lower section held together by bolts, the lower being a single pieces while the upper was made up of a series of units beneath which the concrete was forced. The poles thus made weighed about 2,500 lb., or five times the weight of a wooden pole of the same length.

The tests were conducted with two concrete poles and a 32-ft chestnut pole under the same conditions. It was found that poles of wood showed practically the same deflection as those of concrete up to 2,000 lb., the load being applied at right angles to the pole and at the top. The deformation at 2,000 lb. amounted to 25⅝ in., this loading being far greater than could ever be experienced in actual use. For deflections of less than 15 in. the concrete pole showed no permanent set. The test on one of the poles was carried to destruction and failure resulted at the point where the 24-ft. reinforced rods ended, the concrete being crushed for about 3 ft. above and below the break.

The results obtained showed that the cost of manufacture of such poles should be from $7.50 to $10, as against $4 to $5 for a wooden pole. The cost of wood poles is thus from one-half to two-thirds that of the concrete poles and their life of usefulness is from ten years to a maximum of twenty, whereas the life of a concrete pole is practically unlimited.

◆

METHODS AND COSTS OF APPLYING STUCCO WITH THE CEMENT GUN.

The cement gun is being used a good deal on construction work of different kinds. The methods and costs of its use on certain work will, therefore, be of interest. Mr. R. C. Hardman, superintendent of construction in the U.S. War Department, in a recent issue of Engineering News, describes the use of the gun for placing stucco on the exterior of a small frame building, containing 631 square yards of surface and having 56 door and window openings. The methods and cost of doing the work, as outlined by him, are given as follows:—

The building, which is two stories high, consisted of a main front with two rear wings, in the space between which the gun was stationed, with the sand and cement storages immediately behind. The typical force in the operation of the gun was one man running the engine and gun, two men mixing and sacking dry material and charging hopper, one nozzleman, one laborer to help nozzleman, and two laborers cleaning grounds and screeding.

The entire building was first covered with cheese-cloth, then with a cheap grade of building paper secured by laths running vertically on the studs. This was then covered with mesh reinforcement secured by 1½-in. staples. Grounds were placed on alternate studs to give a stucco thickness of 1¼ in. The panels thus formed were filled alternately to within about ¼ in. of the face of the grounds. The grounds were then cleaned off with a small trowel and about thirty minutes later the stucco was brought flush with their face and screeded off. The screeding was done by unskilled Mexican labor with a straight-edge shod with steel. When these panels were set, the grounds were removed and the panels between were filled in the same way. The work was done in four sections vertically. The top section was done first so that falling material might find a lodging place below. When a section was completed it was lightly sprayed to secure uniform color and cover up joints. The mixture used throughout was one part of Portland cement to three parts of sand.

In shooting the mixture onto the wall the nozzleman stood so that the nozzle was from three to four feet from the wall, and kept the nozzle in continual motion so as not to pile up too much mortar in one place. In accordance with the principle of the device, the dry mixture was mixed with water at the nozzle. The amount of water used was just enough to keep the mortar below the running point. Water was delivered at about 40 lb. pressure. The air pressure used was 26 lb. A higher pressure than this caused too much waste of material (mostly sand) by rebounding and a lower pressure tended to clog the hose with dry material.

The apparatus consisted essentially of an engine, an air compressor and the "cement gun," which is a hopper, having a caisson lock, for receiving the dry material and from which it is forced through a hose to the surface to be covered. As used, the outfit comprised a 4-cycle, 4-cylinder gasoline engine, connected to a 2-cylinder single-acting air compressor by means of belt and pulley operated by a belt tightener. On the front end of the engine and operated by its flywheel was a small water pump for the engine water-cooling system. A second water pump attached to the compressor and operated by its flywheel was available for pumping water to the hose nozzle. Neither of these pumps was used, as the water pressure from the mains was sufficient.

Connected to the air compressor was the hopper or "cement gun" proper. This consisted of two connected air chambers—upper and lower—each closed at its top by a flap valve hinged to swing downward by gravity and closed by outside levers. The feeding mechanism, which consisted of a revolving slotted wheel, was at the bottom of the lower chamber and allowed the dry mixture to fall through and be forced through a hose, at the nozzle of which it was mixed with the proper amount of water.

In operation the lower chamber was first closed by its valve and filled with air. The dry mixture, which previously had been sacked for convenience, was put into the upper chamber, the upper valve closed and the air turned in. As soon as the pressure in the upper chamber equaled that in the lower the valve connecting the two chambers opened by gravity, allowing the dry mixture to fall into the lower chamber where the revolving slotted wheel allowed it to feed through into the hose connected to the bottom of the lower chamber under the feed wheel. When sufficient material had been forced from the lower chamber to allow its valve to be closed, the exhaust from the upper chamber was opened and the pressure reduced until the lower valve was held closed by the pressure in the lower chamber. The upper chamber was then again filled with the dry mixture, so that the feeding and discharge through the hose was continuous and uniform.

The feeding mechanism was operated by a paper wheel and friction disk controlled by a lever. The dry mixture passed through the feed wheel into the hose and was then picked up by air directly from the compressor and forced through the hose. The hose used was a 2-in. steam hose.

In the accompanying table is given an itemized statement [illegible]:

Table Showing Cost of Stuccoing 631 Square Yards of Surface With Cement Gun.

		Cost.	Cost per sq. yd.
Material for lathing:			
Cheese cloth, 631 sq. yd. at	$0.035	$22.09	
Building paper, 56.8 squares [illegible]	[illegible]	17.04	
Wire, 631 sq. yd. at......	0.1278	80.64

stopping, which has a tendency toward clogging the feed hose. Time was also lost by the wearing out of the feed hose about a foot from the hopper, due, apparently, to a whirling motion of the sand as it came from the hopper.

As has been stated, the gun was placed in a recess in the rear of the building so that the entire job was done without moving the plant. Fifty feet of hose was used and all parts were reached by running through window and door openings.

On the whole the apparatus is considered a success, certainly so if used on comparatively large surfaces where little changing of position is required. The quality of stucco secured is the principal argument in its favor.

OUR RAIL MILLS CAN HANDLE THE BUSINESS.

A despatch from Ottawa stated that importations of rails from the United States have been heavy and that Canadian mills could not cope with the demand. Mr. J. H. Plummer, president of the Dominion Steel and Coal Corporation, thinks otherwise. Interviewed at Sydney, he admitted an increased demand, but stated that if it had come to stay, the mills are well on the way to take care of it. It is not clear that the demand is permanent, he thinks. "There is a factor in the case naturally not known to the public. Rail contracts are made each fall for the whole of next season's requirements. The steel companies then proceed to make contracts for the balance of their output of steel. The present shortage represents demands which the railways did not foresee last fall, and it is useless to blame the rail mills. They could not afford to enter on the season's business with any considerable amount of steel unsold, and would be unable to take large extra orders for rails whatever their rail mill capacity might be.

"It is true that we are passing through a period of active railway building but that has been our condition for some years. The present output of 4,000,000 tons would lay over 3,000 miles of railway, and even in these days that represents great growth. In any case, so far from the steel companies being held up as having failed to keep pace with the requirements of the country, they are entitled to credit for having in the face of enormous and sudden growth in the demand for rails, been able to supply 90 per cent. of the consumption."

DIESEL OIL LOCOMOTIVE.

Much attention has lately been paid to the possibilities of the Diesel oil engine. So far it has not been used for locomotive purposes on road or rail, but, as was announced a few weeks ago, Dr. Diesel is at work with Messrs. Sulzer [illegible], of Winterthur, and Herr Adolph Klose, of Berlin, on a 1,000 to 1,200 h.p. Diesel locomotive. Steam locomotives have, of course, been made of much larger sizes, and the above engine will not, therefore, improve on its immediate predecessors in this respect, but it may be expected to show very large economies in fuel consumption. The Diesel engine proposed for this work is of the two-stroke cycle, four-cylinder type, having its cylinders arranged in pairs at an angle of [illegible] deg. The engine is directly geared to the driving wheels, and does not transform its power electrically. An auxiliary engine drives air pumps for giving increased power when starting or when climbing a grade. The whole is expected to weigh about [illegible] tons. It will be seen that this locomotive gives the most direct form of challenge to the steam locomotive.

BRITISH COLUMBIA ELECTRIC RAILWAY.

New rules promulgated by the government of British Columbia will mean that the British Columbia Electric Railway Company will have to invest considerable money in new cars before the first of 1911. The principal regulation is in regard to overcrowding. In Vancouver, particularly, all cars are filled not only in rush hours but also in the early morning. With the new law in force, not only will the company be liable if this continues, but also those who crowd the car after it has its maximum number of passengers according to law. To carry the passengers offering, the number of cars will have to be almost double what it is now. If passengers are not taken care of, there is a provision in the agreement with the city to be invoked.

After a fight of several months' duration, it looks as if Point Grey will come to the British Columbia Electric. The by-law passed by the ratepayers last January was quashed, and since then no cars have been running in Point Grey. There has been complaint from many ratepayers. Now it is proposed to re-submit the by-law to the ratepayers with the necessary alterations, and on September 7th, the voting will take place. With no cars running, building has not been so active in Point Grey as was anticipated early in the year, though the sections reached by the city cars have gone rapidly ahead.

CANADIAN NORTHERN RAILWAY AND VANCOUVER.

The Canadian Northern and the city of Vancouver are still negotiating about a location on False Creek, and it is probable that an agreement will be reached, for the railway wants to get a site for terminals and the city wants the railway. The railway is willing to recoup the city for the $600,000 necessary to extinguish certain riparian rights, the borrowing of which money was approved by the ratepayers two weeks ago. In addition, it proposes certain improvements. On the other hand, some of the aldermen favor a rental basis, suggesting $120,000 per annum, this being reached by a valuation of $20,000 an acre.

After a long rest, the canal project between the head of Burrard Inlet and Pitt River has been revived. This would give the world-famed Coquitlam a sort of direct water connection with the sea.

RAILROAD EARNINGS.

The following are the railroad earnings for the week ended August 21st:—

	1911.	1912.	Increase or decrease.
C. P. R.	$2,267,000	$2,694,000	+ $427,000
G. T. R.	[illegible]	[illegible]	+ [illegible]
C. N. R.	307,500	372,900	+ 65,400
T. & N. O.	37,499	31,899	— 5,600
Halifax Electric	5,706	6,308	+ 602

The gross earnings of the Canadian Pacific Railway for July, 1912, amounted to $12,052,399, the working expenses were $7,604,222, leaving as net profits $4,448,177. In July, 1911, the net profits were $3,703,028. The increase in net profits over the same period last year is therefore $745,1[illegible]

The statement of earnings and operating expenses of the Canadian Northern Railway Company for July shows an increase in net earnings over July, 1911, of $133,000:—

	July, 1912.	July, 1911.	Inc.
Gross earnings	$1,829,700	$1,475,900	$353,800
Expenses	[illegible]	[illegible]	[illegible]
Net earnings	464,600	361,600	133,000
Mileage in operation ..	4,297	3,711	586

CHEAKMUS RIVER POWER.

Messrs. Bloedel, Stewart and Welch, Limited, are applying for permission to develop a valuable water-power on the Cheakmus River, which empties into Howe Sound. The enterprise will be one of the largest of its kind in the province and if carried out will mean the expenditure of several million dollars. Messrs. Stewart and Welch are well known in Canada, being railway contractors, and the proposed power is located close to the route of the Pacific Great Eastern Railway, which will extend from Howe Sound to the north. Sufficient electrical energy may be generated to operate a large section of the railway and also for lighting and power purposes all through the district at the head of Howe Sound.

PERSONAL.

MR. R. F. PACK, general manager of the Toronto Electric Light Company, has tendered his resignation to the directors of that company.

MR. C. R. REDFERN has been appointed roadways engineer of the Department of Works, city of Toronto, in succession to Mr. A. A. Kinghorn, B.A.Sc., who has been appointed in charge of the day labor construction throughout the city.

C. H. C. WRIGHT, B.A.Sc., professor of architecture in the Faculty of Applied Science and Engineering, University of Toronto, has been elected recently a Licentiate of the Royal Institute of British Architects. It is not often this comes to a Canadian, and we congratulate Professor Wright most heartily on the honor.

MR. W. FRANK EVANS has been appointed manager of the new Concrete Reinforcement Department of Alfred Rogers, Limited. Mr. Evans will be remembered as the former chief engineer of the Expanded Metal and Fireproofing Company. He will attend to the sales of "Steelcrete" concrete reinforcement, for which Mr. Rogers has obtained the agency from the Consolidated Expanded Metal Companies of Pittsburg. Alfred Rogers, Limited, have already had extensive experience in concrete construction through the work of the cement sales department, which Mr. J. Lavelle has managed most capably ever since its organization some years ago.

W. FRANKLYN EVANS.

OBITUARY.

GEORGE HALSTEAD, professor of engineering in the Manitoba University, died at his South Lancashire home on August 28th. He became ill while crossing to England and died from typhoid fever.

◆

COMING MEETINGS.

CANADIAN GAS ASSOCIATION.—Fifth annual convention will be held in Toronto, August 24th to Sept 9th, 1912, during the Exhibition. Sec'y-Treasurer. John Keillor, Hamilton, Ont.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June. 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Opening Meeting, Washington, D.C., September 4th, 1912. Other meetings, Business and Scientific, in New York, beginning Friday, September 6th, 1912 and ending September 13th, 1912. Secretary, Bernhard G. Hesse, Ph. D., 25 Broad Street, New York City.

INTERNATIONAL ASSOCIATION FOR TESTING MATERIALS.—Sixth Congress will be held in the Engineering Societies Building, 29 West Thirty-ninth Street, New York, Sept. 2-7, 1912 Secretary, H. F. J. Porter, 29 West Thirty-ninth Street, New York.

ILLUMINATING ENGINEERING SOCIETY.—Sixth Annual Convention to be held at Hotel Clifton, Niagra Falls, Ont., Sept. 16-19, 1912. Secretary, Preston S. Millar, 29 West Thirty-ninth Street, New York.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. The Secretary, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the [illegible]

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh [illegible] Headquarters McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible]

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack; Meets every first and third Friday of each month, October to April, in [illegible]

MUNICIPAL ASSOCIATIONS

[illegible] ASSOCIATION.—President, Mayor [illegible], Hamilton; [illegible] St. Thomas, Ontario.

[illegible] ASSOCIATION OF RURAL MUNICIPALITIES.—[illegible] J. Hingley, [illegible]

[illegible] MUNICIPALITIES.—President, Mayor [illegible]

[illegible] OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary; [illegible]

[illegible] OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, [illegible] Man.; Sec.-Treasurer, Reeve Cardale, [illegible] Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto. Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer [illegible] Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. [illegible], No. 5 Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. [illegible] Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5 Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, [illegible], Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. [illegible]; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan [illegible], Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. [illegible], P.O. Box [illegible], Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
8-31	—Trenching and Backfilling, Edmonton, Alta. (S.)	8-8

(Canora specifications are also on file at the office of The Canadian Engineer, Rooms 617-628, Transportation Building, Montreal.)

TENDERS PENDING.

TENDERS.

Bassano, Alta.—The corporation of the town of Bassano, Alta., invite tenders for the construction of waterworks and sewers. Plans and specifications for contracts "A" and "B" may be obtained from the John Galt Engineering Company, Limited, Winnipeg and Calgary. Specifications for the supply of pipe and castings will be sent on application to the engineers. Geo. B. R. Bond, secretary-treasurer, Bassano, Alta. (See advt. in Canadian Engineer.)

Brandon, Man.—Tenders addressed to Mr. Harry Brown, City Clerk, City Hall, Brandon, will be received until noon of September 27, 1912, for the delivery of two return tubular boilers and stokers. Specifications, etc., may be obtained from A. W. Shaw, engineer, Brandon.

Fort William, Ont.—Tenders will be received at the office of the City Clerk until September 9th, 1912, for the construction of a concrete sewer on Stanley Avenue, from the Kaministiquia River to Superior Street. Plans and specifications at the office of John Wilson, City Engineer.

Franklin, Man.—Tenders for the construction of steel bridge across the Roseau River in township 3, range 4E, will be received until September 5th, 1912, by John R. Witty, Secretary-Treasurer, Municipality of Franklin. Plans and specifications may be seen at the office of the Minister of Public Works, or at the municipal office, Dominion City, Man.

Kingston, Ont.—Tenders addressed to the Director of Contracts, Department of Militia and Defence, Ottawa, will be received until noon of September 16th, for the construction of a model and gun shed at Royal Military College, Kingston. Specifications may be seen and full particulars obtained at the offices of the Officer Commanding the No. 3 Divisional Area and the Commandant Royal Military College, Kingston, Ontario, and of the Director of Engineer Services, Headquarters, Ottawa. (See advt. in The Canadian Engineer.)

Minnedosa, Man.—Tenders for the construction of a public building, will be received until September 12th, 1912, addressed to R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont. Plans, etc., at the office of H. E. Matthews, Esq., Superintending Architect of the Dominion Public Buildings in the Province of Manitoba, Winnipeg, Man.; at the Post Office, Minnedosa, Man., and at the Department of Public Works, Ottawa.

Montreal, Que.—Tenders addressed to the Board of Commissioners, City Hall, will be received until noon of September 10th, 1912, for the construction of sewers in the following streets:—Notre Dame de Graces Ward-Main sewer to Back River, first section. Westmount Avenue and Cote des Neiges Road, Mount Royal Ward. St. Andre Street, Via Jarry, 750 feet southwards. Plans may be examined, and all information obtained in the office of the Engineer Superintendent of Sewers. L. N. Senecal, Secretary, Board of Commissioners, City Hall, Montreal.

Oakville, Ont.—Tenders will be received by C. G. Mar[illegible] Chairman, Board [illegible] W[illegible]ers, Oakville, Ont., until September 12th, 1912, for an extension to the existing water [illegible] completed this season. Plans and specifications may be seen at the office of the Board, Oakville, or at the office of Messrs. Chipman & Powers, Engineers, Toronto.

Oshawa, Ont.—The Director of Contracts, Department of Militia and Defence, Ottawa, will receive tenders until noon of September 17, 1912, for the construction of a new drill hall at Oshawa. Specifications may be seen and full particulars obtained at the offices of the General Officer Commanding the 2nd Division, Toronto, Ont.; Officer Commanding "C" Company, 34th Regiment, Oshawa, Ont.; Town Clerk, Oshawa, and the Director of Engineer Services, Headquarters, Ottawa. (See advt. in The Canadian Engineer).

Port Colborne, Ont.—Tenders addressed to L. K. Jones, Asst. Deputy Minister and Secretary, Department of Railways and Canals, Ottawa, will be received until September 20th, 1912, for the supply and erection of the steel superstructure of an addition to grain elevator at Port Colborne, Welland Canal. Plans and specifications of the work will be on view on and after September 7, at the office of the chief engineer, Department of Railways and Canals, Ottawa; at the office of J. A. Jamieson, designing engineer, Board of Trade Building, Montreal, and at the office of the superintending engineer of the Welland Canal, St. Catharines. (See advt. in Canadian Engineer.)

Port Stanley, Ont.—Tenders for dredging required here will be received until September 13th, 1912, at the office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa, at which place combined specification and form of tender can be obtained.

Regina, Sask.—Tenders for the construction of powerhouse, laundry and refrigerating plants, Regina General Hospital, and addressed to the City Commissioners, Regina, will be received until noon of September 7th, 1912. Full particulars may be obtained upon application to Edgar I. Wenger, Consulting Engineer, Whitmore Building, Regina. A. W. Pool, City Clerk.

St. Catharines, Ont.—Tenders addressed to A. P. Friesman, Secretary of the Board of Water Commissioners, will be received until September 5th, 1912, for trenching and laying of approximately 7,300 lineal feet of 24-inch cast-iron water pipe. Plans, etc., may be obtained at the engineers' office. F. N. Rutherford, Engineer to the Board, 24 Queen Street, St. Catharines, Ontario.

Toronto, Ont.—Sealed tenders addressed to H. F. McNaughten, Secretary, Public Works, Ontario Department of Public Works, Ontario, Toronto, will be received until noon of September 9th, 1912, for all work excepting excavation required in the erection of the Veterinary College at the corner of University Avenue and Anderson Street, Toronto. Also for the heating, plumbing and ventilating of the New Government House, Chorley Park, Rosedale, and for the heating, plumbing and ventilating of the New Dormitory Building at the Institution for the Deaf and Dumb, Belleville. Plans and specifications can be seen at this Department and at the Institution for the Deaf and Dumb, Belleville.

Toronto, Ont.—Tenders addressed to G. R. Geary, Mayor, Chairman Board of Control, City Hall, will receive tenders until noon of September 10, 1912, for the complete supply and installation of a cast-iron sectional steam boiler in Police Station No. 1, Court Street. Full particulars may be obtained at the office of the Property Department, City Hall, Toronto.

Toronto, Ont.—Tenders will be received at the office of [illegible] Street E., [illegible]

Toronto, Ont. Tenders will be received by G. R. Geary [illegible] Property Department, City Hall, Toronto.

Vancouver, B.C. Tenders addressed to the City Clerk, [illegible] Pender Street West, Vancouver, B.C.

Vancouver, B.C. [illegible]

Victoria, B.C.—The Department of Public Works is inviting tenders for the construction of five reinforced concrete sluices in Coquitlam district, for a lock-up at Fort George, for the erection of an industrial school for girls in Hastings townsite, and for school houses at Martin Prairie and North Kelowna.

Victoria, B.C.—The time for the reception of tenders for the construction of the Victoria Harbor, B.C., breakwater, is further extended to Tuesday, October 15, 1912. R. C. Desrochers, Secretary, Department of Public Works, Ottawa. (See advt. in The Canadian Engineer.)

Weyburn, Sask.—Tenders for the erection of a telephone building on lot 10 in block 23, Weyburn, will be received until noon of September 4th, 1912. Plans, etc., at the offices of Messrs. Storey & Van Egmond, architects, Regina, and D. C. McNab, Deputy-Minister, Department Railways, Telegraphs and Telephones.

◆

CONTRACTS AWARDED.

Canora, Sask.—The North Western Electric Company of Regina, have been awarded the contract to install an electric light system in this town at a cost of $20,000.

Kingston, Ont. — The tender of the Ontario Asphalt Block Paving Company has been accepted by the municipal council, providing the company will give a guarantee that will be acceptable to the municipal engineer, Mr. R. J. McClelland.

Lethbridge, Alta.—Messrs. Navin Bros., of Moose Jaw, have been awarded a contract by the Dominion Government for the erection of a new post office in this city. The cost of the work is given as $326,000.

Montreal, P.Q.—Messrs. Ashmore, Benson, Pease & Co., Ltd., of Stockton-on-Tees, England, have been given an order by the Montreal Light, Heat and Power Company to supply and erect at their Outremont station a four lift gasholder of 3 million cubic feet capacity and a steel tank to contain the same. The tank is 184 feet in diameter and 31 feet deep, while the gasholder has four lifts and will be guided by steel lattice standards and girders. It is expected that the work in connection with the erection of the tank will begin some time this week. The foundations having been in the meantime prepared by the Montreal Light, Heat and Power Company. The Canadian-British Engineering Co., Ltd., of London, Eng., and Toronto, are the Canadian representatives for Messrs. Ashmore, Benson, Pease and Co.

Nelson, B.C.—Messrs. John Burns and Son have received the contract to erect a fire hall for the municipal council at a cost of $17,973. Other tenders and prices were:—J. Dancy, $18,974; and Waters and Pasco, $19,300.

Ottawa, Ont.—The contract for the two new fishery protective boats for the Pacific coast is expected to be given to the Dublin Dockyard Company of Ireland. Tenders were called for these vessels in April last.

Vancouver, B.C.—The J. J. Frants Construction Company have received the contract to erect a four-story brick and frame building on Powell Street at a cost of [illegible].

Vancouver, B.C.—Messrs. Wiles and Fisher, were the successful tenders on the contract to erect a two-story mill mill construction warehouse for Mr. J. Harper, of Kamloops. The plans include the installation of a hydraulic elevator and steam heating. The cost of this work is estimated at $16,000.

Vancouver, B.C.—Messrs. F. J. Kelly and Sons were [illegible] for the erection of a six-story apartment house by Mr. D. D. Hutchinson. The cost of this work will be [illegible]

Victoria, B.C. [illegible] have been awarded [illegible] Board of Education [illegible] School at a cost of [illegible] were received from Messrs. [illegible]

Victoria, B.C.—Messrs. Luney Bros. have been awarded [illegible] Other tenders and [illegible]

Isabella Street, Toronto, Ont., treated with Tarvia B.

Toronto's Experience with Tarvia

TARVIA is a dense, viscid coal tar product which retains its viscosity for months and years, despite exposure to weather and dampness. Used as a road binder, it cements the stone together in a tough, plastic matrix, preventing erosion by water or destruction by automobile driving wheels.

The net result to the road builder is a substantial reduction in average annual expenses: to the citizen the result is the abolition of the dust nuisance and a handsome, clean, mudless roadway.

Isabella Street in Toronto received thorough treatment with "Tarvia B" in the summer of 1911. "Tarvia B" is a tar product of such consistency that it flows readily without heat. The macadam was swept clean, "Tarvia B" was applied with a hose from a tank wagon and covered with sharp sand.

The "Tarvia B" filtered into the surface of the macadam and acted as a binder. The street then remained practically dustless the remainder of the season and still continues to be a beautiful bituminous surface.

Next summer probably another treatment will be desirable at a cost of less than three cents a yard and that will take care of the street for another season, making sprinkling unnecessary, abolishing the dust nuisance and preserving the road against the destructive action of automobile wheels.

This is not road repairing—it is genuine road maintenance. The adoption of this policy in any town means the preservation of the roads year after year in excellent condition at much less cost than with any other method of upkeep.

Booklet regarding Tarvia will be sent free on request.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER
THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S.

Winnipeg, Man.—The addition to the Industrial Bureau, now under construction, is being done by the James McDiarmid Company. J. D. Atchison is the architect. The cost is placed at $45,000.

◆

RAILWAYS—STEAM AND ELECTRIC.

Hamilton, Ont.—The management of the Canadian Pacific Railway has recently placed an order with the National Car Company to furnish 1,500 box freight cars.

Ottawa, Ont.—The Department of Railways and Canals have recently received the approval of the cabinet to purchase nineteen powerful locomotives for use on the Intercolonial in Eastern Canada.

Saskatoon, Sask.—Mayor Clinkskill has announced that after an investigation, conducted by himself, this city will save $8,000 per year in the operation of single truck cars in the place of double trucks on the new street railway system that is soon to be in operation in this city.

Vancouver, B.C.—The officials of the Canadian Northern Railway have formally requested the municipal authorities to turn over the ownership of False Creek. If the gift is made the railway agrees to spend the sum of $10,000,000 on reclaiming 200 acres of land and the erection of depot buildings with entrance work.

Welland, Ont.—The Canadian General Securities of Toronto, have received the sanction of the ratepayers to construct a street car line through a portion of their lands in the industrial section.

◆

LIGHT, HEAT AND POWER.

Edmonton, Alta.—The municipal commissioners have received a report from Mr. B. R. Campbell regarding a located natural gas well two and one half miles from the city limits. [illegible]

Canora, Sask.—The ratepayers recently endorsed the expenditure of $20,000 on a municipal electric light plant.

County of Bruce, Ont.—There is a movement on the part of certain residents of this country to induce the authorities to examine the power production possibilities of the Saugeen [illegible] r Rivers, as it is understood that some time must [illegible] the energy furnished by the Hydro-Electric Com- [illegible] l be offered for sale in this portion of Ontario.

Pense, Alta. A valuable flow of natural gas was located [illegible]

Stave Falls, B.C. [illegible] to the British Columbia Electric Com- [illegible] nish this extra output. Mr. C. H. Cahan, Mont- [illegible]

Victoria, B.C. [illegible]

GARBAGE, SEWAGE AND WATER.

Brockville, Ont.—A recent investigation of the drinking water by the Provincial Board of Health indicates that the water is contaminated. The citizens have been advised to boil that used for drinking.

Galt, Ont.—A large deputation of citizens from towns and cities near this point, waited upon Premier Whitney regarding a proposed commission to investigate the conditions along the Grand River, and prepare a report on the best manner of removing or remedying the evils of floods due to spring freshets. Mr. W. H. Breithaupt, Berlin, Ont.

Lindsay, Ont.—The municipal council have authorized the laying of a drain about 1,400 feet long. Tenders for the laying of the tiles will be called in a few days. Mr. Smith, engineer to the council.

Paris, Ont.—The municipal council have examined a sewerage system designed by Mr. Chipman, of Toronto. The estimated cost of this work will be about $40,000. The report and plans are to be considered by the committee of streets and sidewalks.

Pense, Alta. A tremendous flow of water was struck at this place recently when drilling operations had reached a depth of 1,500 feet.

St. John, N.B.—The municipal commissioners are considering the installation of an incinerator at a cost of $55,000. The mayor of this city has been authorized to enter into correspondence with a firm in New York who will supply this refuse burner at the price given. W. F. Murdock, city engineer.

Toronto, Ont.—The municipal Property Commission will proceed with the erection of a chlorinating plant inconnection with the septic tanks at Morley Avenue.

Victoria, B.C.—Plans for two garbage stations are completed and tenders will be called in a few days. These are to be erected at Spring Ridge and Fairfield. C. H. Rust, city engineer.

Victoria, B.C.—The Provincial Department of Public Works is inviting tenders for the construction of five reinforced concrete sluices in the Coquitlam district

Victoria, B.C.—Samples of water recently examined from Sooke Lake, the future source of water supply for this city, have shown that the organic qualities are well suited for the needs of a growing municipality.

AGENTS FOR CANADA **LAURIE & LAMB,** ENGINEERS, MONTREAL

Niagara Falls, Ont.—The management of the Visor Knitting Company, of Niagara Falls, New York, will, in all probability, open a branch plant at this point in the old armory building. Considerable alterations will be necessary to the building.

Regina, Sask.—A report states that the management of the Canadian American Egg Company will establish a branch plant in this city. The members of this company state that they have received from Denmark particulars of a system that will keep eggs fresh for a period of two years. Mr. Hammer is president of this concern.

Township of Crowland, Ont.—Four industrial by-laws in connection with the Canadian Northern Steel Company and the Canadian Terminals, have been endorsed by the ratepayers.

Vancouver, B.C.—The management of the Woodward Department Stores have recently completed the purchase of a block of land and will erect a six story steel addition to their present building. Mr. W. C. Woodward is an official of this concern.

Victoria, B.C.—The Provincial Department of Public Works will call tenders for the erection of an industrial school, for girls, in the Township of Hastings, also for the erection of school houses at Martin Prairie and North Kelowna.

◆

BRIDGES, ROADS AND PAVEMENTS.

Kildonan, Man.—The council of this place are considering the erection of a bridge over the Red River, and should the ratepayers of Winnipeg endorse the purchase of a new exhibition site it is probable that the structure will be built. The estimated cost of the work is about $85,000.

◆

FIRES.

Montreal, P.Q.—About $60,000 damage was caused by fire to the plant of the sash and door factory of Mr. Walter Reed.

Newville, N.S.—The buildings and plant of the Newville Lumber Company, were destroyed by fire with a loss of $20,000. This place is ten miles from Parrsboro.

Peterboro, Ont.—An explosion at the plant of the Canadian General Electric Company caused serious damage. The sub-station was partially wrecked.

St. John, N.B.—The plant of the Wilson Foundry, owned by Hon. J. E. Wilson, and the plant of the Canada Brush Company, were destroyed by fire with a loss of about $100,000.

◆

CURRENT NEWS.

Edmonton, Alta.—The municipal council will request the [illegible] by-laws on September [illegible] for the purchase of a [illegible] in Woodward [illegible] for a telephone sub-station [illegible] and [illegible] for the establishment of a plant to manufacture, distribute, and supply gas.

Frank, Alta.—[illegible] at Ottawa [illegible] completed for [illegible]

Fredericton, N.B.—[illegible]

Halifax, N.S.—[illegible]

Medicine Hat, Alta.—Announcement is made of an appropriation to be passed at the next session of the legislature for the purpose of installing an automatic telephone system in this city. A new telephone headquarters is also included in the estimate. Mr. Harman, Deputy Minister of Telephones for Alberta.

Montreal, P.Q.—A report states that the large dry dock for this port has been shipped from the yards of the makers in England. If this is a fact the dock should be in position about October 1st next.

Ottawa, Ont.—For the construction of the proposed dry dock at Quebec, the Federal Government has received but one tender for the work and this is an offer to construct the scheme on a straight cash basis in place of the subsidy method as advocated by the Government.

Prince Rupert, B.C.—The management of the Canadian Fish and Cold Storage Company, Ltd., will, in a short time, have twelve new fishing boats for use in their business. The first of these is almost completed in Vancouver. The vessels will be 85 feet long, 18 foot beam and a depth of hold of 9 feet 7 inches and of schooner rig, equipped with 125 horse power gasoline engines. They will cost about $16,000 each. Mr. Geo. H. Collins is managing director of this company.

Province of Saskatchewan.—Engineers engaged on the Dominion Government work of surveying the Saskatchewan River for the proposed Winnipeg to Edmonton canal route have arrived at Prince Albert for the winter.

Toronto, Ont.—It is probable that the ratepayers will be asked to vote on the by-law calling for the erection of civic incinerators next January.

◆

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the Office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending August 19th, 1912:—

Inquiry is made by a London firm of mineral water manufacturers for the names of Canadian producers and shippers of apple juice.

A Lancashire correspondent desires to get into communication with Canadian firms in a position to export hard timber adze trimmed to 5-in. and 8-in. diameter, to cut into lengths of 2-ft. 4-in. to 2-ft. 8-in.; also timber adze trimmed from 24-in. diameter and to cut into lengths from 30-in. to 48-in.

A correspondent in the south of England makes inquiry for the name of a London importer of Canadian evaporated milk.

A North of England correspondent is open to undertake the representation of a Canadian firm manufacturing a proprietary article which they desire to place on the market in Great Britain.

A Yorkshire firm manufacturing gas, oil and spirit engines and suction gas plants desire to get into touch with likely importers or agents.

Inquiry is made for the names of Canadian shippers of ash or hazel twigs, [illegible] for use in the manufacture of handles for stone-breaking hammers.

An import agent at Berlin would like to secure the representation of some Canadian firms open to do business in Germany.

A Dutch correspondent makes inquiry for the names of Canadian importers of cement.

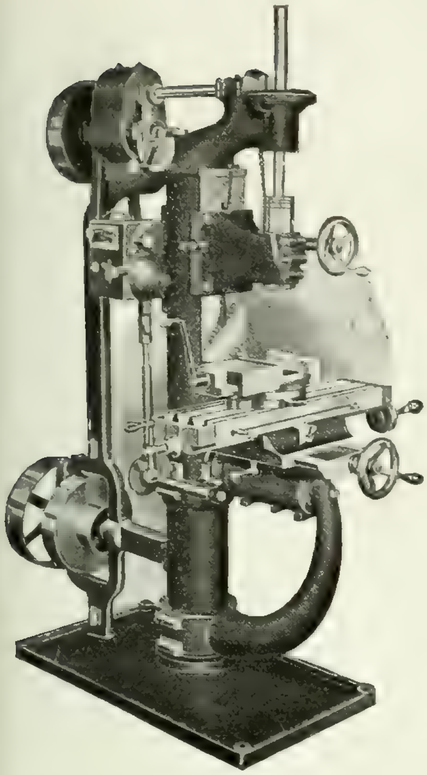
A Toronto manufacturers' agent offers to undertake the Canadian representation of United Kingdom manufacturers, and to arrange for transportation from the United Kingdom ports to all points in Eastern Canada.

From the Branch for City Trade Inquiries, 73 Basinghall Street, E.C.:—

A [illegible] firm manufacturing car pit equipment plant for dealing with electric tramcars, etc., and also engineering tools, wish to arrange for their sale in Canada.

A [illegible] company manufacturing various kinds of paper, [illegible] and other stationers' and bookbinders' supplies, are seeking suitable Canadian resident agents.

A [illegible] manufacturing all varieties of colors [illegible] for suitable Canadian buying agents, preferably in Montreal and Toronto, to whom they would grant their exclusive agency for the whole of the Dominion.



You Need a Machine Like This on a Dozen Different Jobs

It's a No. 2 Knight Milling and Drilling Machine

This machine is very rigid, powerful and accurate, so that close work may be turned out with a high degree of satisfaction, and in the shortest possible time. The adjustments are quickly and easily made. On a large variety of work it is possible to make a saving of from 20 to 50 per cent. in time, as compared with other machines.

The fact that hundreds of Knight Machines are now in use in this and foreign countries proves that they are not experiments.

These machines are made in three sizes.

Briefly, the construction of the No. 2 Knight Miller is as follows:—Spindle of crucible steel, ground bearings; working surface of table, 29 × 8½ inches; feed, longitudinal and transverse; floor space, 60 × 68 inches; weight, crated for shipment, about 2,500 lbs.

PATENTS.

The following is a list of patents recently issued to investors by the Patent Office in Ottawa. The list is furnished by Messrs. Fetherstonhaugh & Co., 10 King Street East, Toronto:—R. J. Little, detachable runners for vehicles; A. W. Anderson, flexible films; S. Barnes, cupolas; Wm. R. Bell, Grain tanks; S. Bellemare, ventilating systems; R. W. Burnett, hose protectors; Chas. F. Deck, sashes; I. DeFoy, automatic regulating valves; Ed. Heitman, squirrel cage rotors for electric motors; R. C. Morrow, combined rail chairs and splicers; Jno. Murphy, water controlling apparatus; Wm. H. Roughsedge, floor molds for concrete buildings; Jno. B. Shelton, freight refrigerator or cattle cars; A. E. Spooner, gravity door locks; N. H. Stovell, combination chamfering tools; W. H. Taylor, separable umbrellas; O. Woodall, neckband measuring devices; Thos. H. Knox, vehicle wheels; A. Lewis, berry boxes; O. R. Loewenthal, composition powder for cockroaches; Wm. Maloney, single monorail track constructions; R. C. Morrow, rail chairs.

◆

PULPWOOD PRODUCTION

Pulpwood exported in the raw state during 1911 amounted to 847,939 cords, and fifty-four firms reporting to the forestry branch of the department of the interior used 672,288 cords, making a total cut of 1,520,227 cords valued at $9,678,616. This is 21,401 cords less than was cut in 1910, but the quantity manufactured in Canada was larger, states Mr. H. R. MacMillan, B.S.A., M.T., in an interesting bulletin just issued. Over 95 per cent. of Canadian mills cut the pulpwood used by them from their own limits and consequently ross the wood themselves. Altogether 73,801 cords of wood (i.e., 12.3 per cent.) more were used in 1911 than in 1910. The average price of the wood also increased, so that the value of the domestic pulpwood industry was greater in 1911 by $752,870, or 21 per cent. The average price per cord was $6.07 in 1908; $5.57 in 1909; $6 in 1910; and $6.45 in 1911. Only 22,229 tons more of pulp were produced in Canada in 1911 [illegible] in 1910.

There was a decrease of 93 pounds in the amount of pulp produced per cord of wood; it is difficult, however, to secure trustworthy data as to the output of pulp, since many firms do not give the air-dry weight.

Quebec is the premier pulpwood province of Canada, because of its extensive spruce and balsam fir forests fit for pulpwood, its abundant and cheap water-power and its plentiful supply of labor. The 28 mills in Quebec reported a consumption of 58 per cent. of the total for Canada, or 47,671 cords more than in 1910. The quantity used was 13.9 per cent. more than in 1910, and the value 33.9 per cent. greater. Ontario, although suffering from the flooding of one mill, increased the amount consumed in its fourteen pulp-mills by 3,115 cords, and used nearly one third of the total production. New Brunswick is recovering from the depression of 1910, and contributed 45,824 cords, or 6.8 per cent. of the total. In 1909 it used 88,450 cords, being 14.2 per cent. of the total, so the recovery is still incomplete. In Nova Scotia, where one large mill was burned early in the year, the consumption has increased by 115 cords as com- [illegible] 1911. The province of British Columbia is still experimenting in pulpwood manufacture, and the negligible amount reported from this province is manufactured for test purposes only.

[illegible]

[illegible]

spruce, 3,718 cords less of balsam fir, 2,096 cords less of hemlock, and 641 cords more of poplar. New Brunswick also showed a large increase in the spruce used.

Although the reports furnished from the mills do not indicate it, the proportion of balsam fir used is yearly increasing. Balsam fir and spruce are used in mixture in the manufacture of news print. A few years ago it was thought that if the proportion of fir was increased above twenty-five per cent. an inferior paper would result. Greater skill in papermaking has shown that the proportion of fir may be increased to forty per cent. or over. This is now being done by some mills and the resulting paper has proved satisfactory. In various parts of Eastern Canada, particularly in Quebec, balsam fir forms from twenty to fifty per cent. of the forest. The practice of the companies now operating is to take spruce and balsam as they occur in the forest. On account of the prejudice still existing against balsam fir, it has not been expedient for the mills to keep track of or report the exact proportion of balsam fir used. Hemlock, which was third in 1910, has retired to fourth place in 1911. Although it has fallen off nearly 60 per cent. since 1910, more than twice as much of it was used as in 1909. There is reason to suppose that a larger export of hemlock took place. While more poplar manufactured in 1911 than in 1910, it is still below the amount for 1909. Jack pine has not been reported as a pulp wood since 1908. Before that time it was used considerably by two large mills, but has proved unsatisfactory. Arrangements are now being made by mills in Ontario and Quebec for a further use of jack pine.

The average price of the different species used is the cost to the mill-owner, and so includes varying logging expenses and a wide difference in transportation charges. Maximum and minimum prices for a species in a single province may differ by 100 per cent. The great majority of pulp-mill owners have their own timber limits, and to them the cost of their pulp logs is merely the cost of carrying the limit and the operating charges. Other operators buy in the open market and add transportation charges. Thus the prices quoted are the purchase prices under different conditions, and do not show the relative value of the different woods for pulp manufacture.

The effect of an excessive hauling distance is demonstrated in Ontario, where the prices of spruce and balsam fir were $6.75 and $7.46 respectively. The high price paid for balsam fir and the sustained demand for this species proves its suitability for manufacture into pulpwood. Over the whole of Canada spruce was the most expensive species at $6.47 or 42 cents more than in 1910. Balsam fir is at $6.40, having risen 69 cents since 1910. Hemlock, though still the cheapest species, advanced 75 cents per cord, its average price in 1911 being $5.18. Poplar has advanced 25 cents over 1910, the price last year being $6.17. The cheapest pulpwood bought was a small quantity of poplar in Nova Scotia, which cost $3 per cord. A small quantity of hemlock in British Columbia at $7.60 was the most expensive wood, on the average, used in Canada for pulping; but as much as $10 per cord was paid for spruce in some cases.

During 1911, no slabs or saw-mill waste were reported as being converted into wood-pulp in Canada, but from the reports made to the forestry branch by saw-mill operators it would appear that a very small quantity of mill waste is so utilized by three companies operating saw-mills and pulp mills under the same ownership. This is an economy practised to a greater extent in other countries, and by neglecting it Canada is losing greatly. It has been conservatively estimated that if all useful logs left in the bush by lumbermen, large-sized branches, slabs and other mill waste from the lumber industry in Canada, had been converted into pulpwood in 1911, the annual output of pulpwood would have been increased [illegible] have been cut over for logs to [illegible] pulp only. During 1910, in the United States, six and a half per cent. of the total consumption was from slabs and mill waste. If economy had been practised to the same extent in Canada during the year 1911, as much pulp [illegible] without cutting one additional pulp log, as is manufactured from over 43,000 cords of wood. [illegible] pulp as New Brunswick produced in 1911. The sooner such practical economy and utilization of waste commences, the longer will Canada have an adequate supply of pulpwood.

The Canadian Engineer
An Engineering Weekly

THE AWAKENING OF CANADIAN IRRIGATIONISTS.

By NORMAN S. RANKIN.

NOTE.—A report of the Sixth Annual Convention of the Western Canada Irrigation Association, held at Kelowna, B.C., Aug. 13th. to 16th. Mr. Norman S. Rankin, the Secretary of the Association, who has furnished us with this account of the Convention is Publicity Manager for the Department of Natural Resources of the Canadian Pacific Railway Company.—EDITOR.

"Great oaks from little acorns grow." "Great streams begin as tiny springs," and so great companies and organizations oft-times have their birth in tiny, dark offices, with out-at-elbows desks, and an executive who is at once president, vice-president, general manager, private secretary and office boy.

Everybody interested in irrigation and agriculture in the United States has heard of the National Irrigation Congress. All know what a powerful, influential organization it is to-day, and how delegates from the four corners of the country come together, year after year, in some chosen city, to follow the deliberations and resolutions of that association. They also know that the resolutions of that great congress go up to the Senate at Washington, and there meet with careful, serious consideration.

The Delegates Being Entertained at Kelowna.

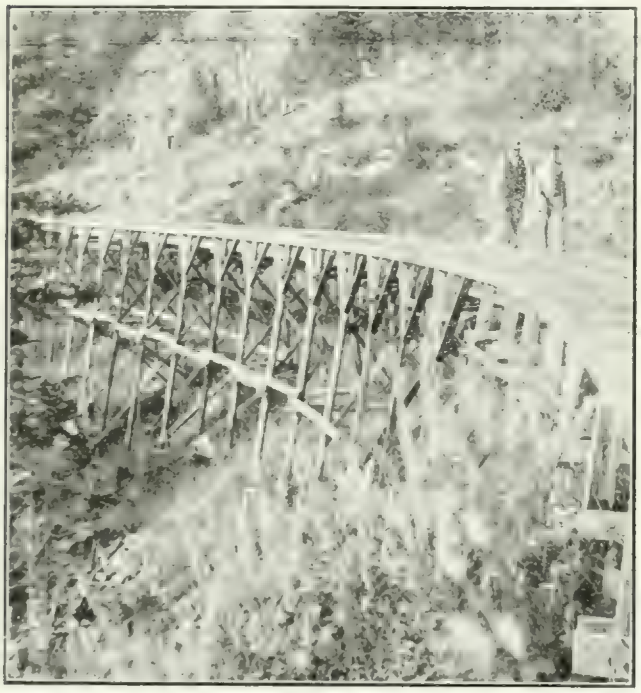
North of the boundary line, the National Irrigation Congress, six years ago, had a little baby brother, known as the Western Canada Irrigation Association. It was then struggling its way through the ills and fevers of babyhood, but now has developed into a sturdy child, standing upright on its own legs, and looking the irrigation world in the face. Very few below the line know that this continent holds a second irrigation association, but the result of its sixth annual convention, held at the beginning of August at Kelowna, in the Okanagan Valley, British Columbia, has clearly demonstrated that the one-time infant will from now on make itself heard.

The Western Canada Irrigation Association—which has practically the same aims and objects as its big brother in the United States—has slowly but steadily extended its scope of endeavor until under its influence has fallen every up-to-date farmer and irrigator in the Western Canadian provinces of Saskatchewan, Alberta and British Columbia, and when this year its interesting and attractive official call went forth the response was hearty and encouraging.

To Kelowna then—a charming little fruit city beautifully situated on the borders of Okanagan Lake—came during August 13th, 14th, 15th and 16th, farmers, irrigationists, students, railroad and government officials and politicians. They left the main line of the Canadian Pacific Railway at Sicamous, and journeying down the fertile Okanagan Valley, reached at length the picturesque lake of that name, and boarding the huge stern-wheeler that awaited them, were borne swiftly to their destination—appropriately named, "The Orchard City." Here with open doors and flying banners, the hospitable citizens awaited them, and visitors were whirled away in automobiles to the various homes and hotels which were prepared to receive them.

View of Kelowna Beach and Bathing Place.

That evening, at eight o'clock, in the local theatre, some five hundred interested irrigationists listened to Mayor Jones' welcoming address, while on the platform sat such distinguished men, as the Hon. W. R. Ross, Minister of Lands, B.C.; J. S. Dennis, assistant to the president, Canadian Pacific Railway; the Hon. Dr. Samuel Fortier, chief irrigation investigations, U.S.A.; Sir William Willcox, an eminent irrigationist; Professor Alfred Atkinson, Department Agronomy, Agricultural College, Bozeman, Montana; John T. Burns, executive, secretary-treasurer, International Dry Farming Congress; the Hon. Price Ellison, Minister Finance and Agriculture, B.C.; Deputy Minister W. E. Scott, B.C.; Professor M. L. Dean, State Horticulturist, Missoula, Montana; A. S. Dawson, chief engineer, Department Natural Resources, C.P.R.; R. M. Winslow, provincial horticulturist, B.C.; P. L. Naismith, manager, Alberta Railway and Irrigation Co.; F. H. Peters, Commissioner of Irrigation, Dominion Govenment; R. H. Campbell, Director of Forestry, Ottawa; Professor C. I. Lewis, Corvallis, Ore.; George Harcourt, Deputy Minister of Agriculture, Alberta, and a [illegible].



Steel Flume of the Kelowna Land and Irrigation Company, British Columbia.

In the audience were delegates from as far west as Victoria, and as far east as Ottawa, gathered to discuss and resolve what was best for the farmer, and best for the [illegible].

[illegible] to the Okanagan Valley and Kelowna in particular, Mayor Jones stated that during the past year nearly half a million dollars had been expended on irrigation works. One hundred and thirty thousand fruit trees had been planted on irrigated lands last [illegible], while the tobacco industry is assuming great im[illegible]

J. S. Dennis, the father of irrigation in the west, vice-[illegible] mittee, in speaking of the Provincial Government and the [illegible] that was of supreme importance, and in order to make it successful, the government required the energetic co-operation of all users of water. All development depended on the proper administration of the Act; value lay not in the land but in the water, as the greater portion of the land in the dry belt of British Columbia would produce nothing unless irrigated. Land above the ditch was worth from $5 to $20 an acre, while that below was valued at from $100 to $400 per acre. The difference was not due to soil or climate, but to the water. It was, therefore, just as important that the law regarding title to water be as definite as that regarding the title to land, but until everyone gave loyal support to the government in the administration of this Water Act, the title to water would not be as good as to land. He spoke of the history, aims and work accomplished by the Western Canada Irrigation Association, and said that the present convention was attended by a larger number of delegates than the previous five. Perhaps this was surprising in view of the remoteness of Kelowna from the main lines of communication, but it was not when it was remembered that British Columbia was looming up as the most attractive part of the West to people south of the line and in the Old Country. From the latter country, the people came to British Columbia readily because the name itself was attractive to them, and it seemed like coming home. There was great need of taking care of these people when they arrived, and he suggested that more complete surveys of government land were needed in order to supplement the Water Act. Southern British Columbia, he believed, was now on the verge of sharing in the great movement from the south which had been greatly increasing during the past few years, and had been directed almost entirely to the western provinces. This year it would total over 150,000 people, and this "spilling over the brim" of the 100,000,000 of the population of the United States would extend to British Columbia. He said that he saw in the future all valleys from the boundary to the main line of the C.P.R. filled to their entire capacity with prosperous settlers.

Each speaker during the convention had something of interest to say to the delegates, and were followed with close attention. The Hon. Dr. Fortier delighted the audience one evening with a stereopticon lecture on "Irrigation in California," and the proceedings were occasionally broken [illegible] a little [illegible] jaunt into the country to inspect [illegible] schemes under operation or construction. [illegible] of great import to the country were taken up, [illegible] and passed on to the government for consideration, while vital subjects such as "The Apple and the Baldwin Spot," "The Irrigation of Alfalfa," "Public Ownership

Orchards at Penticton, British Columbia.

of Irrigation Systems," "Irrigation as Applied to Forestry," and kindred subjects were discussed and resolved.

With a delightful steamboat trip down the lake to Penticton, touching at Summerland, Peachland, Naramata and other points, and a monster banquet, tendered by the citizens of the town of Penticton, at the new Incola Hotel, the convention adjourned to meet in August, 1913, in the ambitious city of Lethbridge, Southern Alberta. So keen was the interest shown in future conventions of the association that bidding for the 1914 and 1915 conventions has already commenced. In 1914 it will again meet in British Columbia, and in 1915 in Alberta, thus carrying out the accustomed procedure of the association to hold its conventions alternately in the two provinces.

The following officers were elected for the ensuing year: Hon. President, the Hon. G. A. V. Bulyea, Lieutenant-Governor, Province of Alberta; president, Hon. Duncan Marshall, Minister Agriculture, Alberta; vice-president, W. C. Ricardo, manager Coldstream ranch, Vernon, B.C.; vice-president and chairman, J. S. Dennis, assistant to president C.P.R., Calgary, Alberta.

Executive Committee.

West of Mountains.—Thomas Bulman, Kelowna, B.C.; F. K. Fulton, K.C., Kamloops, B.C.; J. A. Mackelvie, Vernon, B.C.; C. W. Dickson, Kelowna, B.C.

East of Mountains.—A. S. Dawson, Calgary, Alta.; W. H. Fairfield, Lethbridge; Wm. Pearce, Calgary, Alta.; Prof. W. J. Elliott, Strathmore, Alta.

Official word has been received from Lethbridge that "The Ambitious City" proposes to make the 1913 convention the most interesting and attractive in the history of the association.

◆

APPRENTICES ON THE CANADIAN PACIFIC RAILWAY.

The education of the apprentices on different classes of work is demanding more and more attention from the employer of labor. The railroads have appreciated the necessity of providing such education before other branches of industry. In an article in a recent issue of "Railway and Locomotive Engineering" Mr. E. E. Bailey, the supervisor of apprentices on the western lines of the Canadian Pacific Railway, outlines this company's methods of approaching the question. Mr. Bailey says that considerable attention is paid to careful and systematic education, both practical and theoretical, in the various trades required for the production of the shops at Winnipeg. A well-organized apprentice instruction department, in charge of a supervisor of apprentices under the direction of the superintendent of shops, controls the hundred apprentices employed at Weston, both in their shop training and in their instruction classes. Those learning the machinist trade, about two-thirds of the total number, have also a shop instructor, who is employed to devote his time to showing the boys how to handle their various jobs, and who is responsible for passing them efficiently through the many branches of their trade in due order, scheduled periods for each being allotted. The remainder, including boilermakers, blacksmiths, moulders, pipefitters, tinsmiths, carpenters and patternmakers, are under direct control of their respective foremen. A careful record of their progress, behavior and aptitude is returned to the supervisor, particular attention being paid to inculcating the habit of good timekeeping; twice late per month, or a total of twelve per annum, only being allowed, together with a total loss of time each year of a hundred hours, this being allowance for vacation. Any time over this has to be made up before the boy can receive his increase of pay, which rises automatically from 13 cents the first year to 17 cents the second, 20 cents the third, 23 cents the fourth, and 26 cents the fifth, after which, on receipt of a satisfactory certificate of apprenticeship, they step at once to the schedule rates as tradesmen.

The technical or theoretical training, rightly considered as of great importance, is developed by means of classes conducted by the supervisor, fifteen boys being the average per class. In arithmetic all are taken through fractions, decimals, proportion, averages and roots and powers, and concluding with mensuration. In drawing they are instructed first in freehand, to be applied later in their training to the making of shop sketches. Then geometry, projections, intersections and developments of surfaces, and finally to the making and reading of shop or mechanical drawings, each trade being given, as far as is possible, subjects bearing on their own class of work.

Beyond this any apprentice who elects to pay a small sum per month may continue his studies in more advanced subjects, such as algebra, logarithms, trigonometry, advanced mechanical drawing, steam and kindred subjects, the company's object being as much to enable the boys to realize the advantages of extending their technical knowledge as it is to give all a good training in the rudiments.

During their first year as apprentices, when they must be sixteen years of age or over, they receive two hours' instruction per week; from then for the following two years, four hours per week is given, divided into two sessions of two hours each. At the end of the third year their theoretical training ceases, unless, as stated above, they wish to advance further, when they may continue to attend special classes until they have completed the branch of study chosen, or until they have completed their apprenticeship.

A monthly record of school and shop progress is sent to each boy's parent or guardian, and copies are kept charted up in the Instruction Room for friendly rivalry and emulation. Each December an examination on the general progress of the classes is held, scholarships being presented to the five boys with the highest marks. All apprentices are also eligible to compete for the two scholarships offered by the company covering four years' free tuition in the Faculty of Applied Science of McGill University.

It will thus be seen that generous encouragement is given to every boy entering the Winnipeg shops as an apprentice, and that no effort is spared to turn out in the finished article a thoroughly well-trained and useful member of a trade, and it must be said that the boys themselves appreciate the efforts of the company to this end, and evince a willingness to learn, and an interest in their work, to go far to justify the trouble and money expended upon their training, and finally result to their own particular advantage in the coming years.

THE NEW QUEBEC BRIDGE.

Work is progressing rapidly on the new Quebec bridge. Last year the debris of the fallen structure, a vast mass of tangled steel, partly above the water and partly submerged, was removed and new caissons were sunk, so that the work on the substructure may be considered well enough advanced to predict a completion of the new bridge in 1915. The bridge when finished will be one of the greatest of its kind in the world. Pending its completion, trains of the new Transcontinental will be transferred across the St. Lawrence by ferries.

COMPENSATING GRADES FOR CURVATURE.

The subject of compensating grades on curves in order to offset the increased train resistance due to curvature crops up periodically, and it is evident that practice in this direction is not only very diverse but is based upon a very uncertain foundation. The following article was compiled and published by the Engineering News, and presents the whole matter so fully that we reproduce it in full. It is mentioned in the early and noted "Shunk" and "Searles" field-books, the former giving a formula which is quoted below (by Mr. Beahan). In "Field Engineering" (1887), by W. H. Searles, the curve resistance (lb. per ton) on a curve of given degree is stated as 0.56 x D, while the grade (per cent.) on tangent having the same resistance as the given curve is stated as 0.025 x D. Thus the resistance and compensation were assumed to vary directly with the degree of curve, which is now almost universally recognized to give incorrect results. On the subject of compensation, Mr. Searles stated as follows:

"In locating a road, the maximum grade should be reduced on a curve by the amount of the equivalent grade of the curve [see formula above.—Editor.] so that the resistance may be no greater on the curve than elsewhere. But grades less than the maximum need not be reduced for the curves upon them, unless the sum of the grade and the grade equivalent exceeds the maximum."

The most extensive analysis (and we might say the only thorough analysis) of the subject is that given in Wellington's "Economic Theory of the Location of Railways" (1887), and we recommend a careful study of the exposition there given, with the reservation that the reader should remember that the conclusions may not apply directly under modern conditions of rolling stock and traffic. As a compilation of opinions on the subject would be incomplete without some outline of those of Mr. Wellington, we give below a few extracts together with his summary of conclusions:

Under three different conditions curvature may come (in advance of gradients) as a limiting agent to fix the weight of trains:

1. [illegible] on a maximum grade without reducing the rate of the latter by compensation for curvature, so as to keep the aggregate resistance constant on both curves and tangents. 2. When a line is nearly or quite level, and yet runs through a region requiring curvature which (as is very apt to happen on such lines) cannot be compensated [illegible] there are no grades, or no sufficiently high grades to reduce, in order to eliminate their additional resistence. 3. When on lines of the latter (or any other) class curvature of such short radius is used as to limit the length of trains more than would the same amount of curvature with longer radii. These causes are more or [illegible]

[illegible]

Under these circumstances, prudence would indicate that wherever there is no physical limit to the possible reduction of grade on curves, it should be made ample, so that the curves should certainly offer no greater resistance than the adjacent tangents. At stations this rule would require a grade reduction of 0.1% per degree.

On the other hand, when we are merely trying to equalize the tangent and curve resistance on a long ascent, and whatever is taken off the curves must be added on to the tangents, no such practice is proper. If we come as near to an exact equality as we can, in compensating for curvature, it is of no importance whether our compensation is a little too great or a little too small. In the one case trains will stall on the tangents and in the other on the curves; that is all. Our object is simply to guard against a certainty of stalling on either. Nothing more than this is important.

Hence it may well be that on a long and crooked ascent, where the curvature greatly exceeds the tangents, yet where there are one or two considerable tangents, prudence will require the assumption of a very low rate of compensation; for otherwise a very slight loss of elevation on each curve, multiplied by many curves, will prevent our attaining the desired summit without a considerable increase of the normal tangent grade. If we have guessed right as to the real curve resistance, this may do no harm; but, on the other hand, if we have guessed wrongly, and exaggerated the probable curve resistance, we shall have unnecessarily increased our tangent grade. Hence, by assuring a low rate of curve resistance in such a case, we can hardly in any case lose anything appreciable, and may save a needless loss of grade. A compensation rate of 0.03% per degree of curvature may then be proper, below which the rate of comsation should never fall.

For the same reasons, it may well happen that at different points on the same line different rates of compensation may be proper. Where the loss of elevation by a high rate of compensation is a very serious matter, because of a great amount of curvature, it may be taken at a minimum. At other points, where there is less curvature to be compensated and a higher compensation can be had at little or no cost, it should there be used. The effect will be to make most of the maximum grade scattered over the division a little easier to handle trains on than the longest or worst grade. This may well result in handling a car or two more than would be deemed possible were the resistance as great at two or three points as it is at one.

It is always worth while to keep a little below the maximum where possible, at moderate cost. This is only another application of the same principle, but, owing to the uncertainty which hangs about the question of curve resistance, it is a wiser way of attaining the same end than to reduce the nominal tangent grade, especially in the vicinity of stations.

Conclusions. 1. With short grades or under favoring topographical conditions compensate as liberally as possible up to a maximum at special points of 0.10% per degree.

2. Where speed may sometimes be very low, and hence invariably on or very near to known stopping places, this maximum rate appears, with our present knowledge, none too much. In general, however, 0.05% per degree (= 1 lb. per ton) is an ample equivalent for curve resistance, and for fast trains alone probably 0.02 to 0.03% (= 0.4 to 0.6 lb. per ton) is sufficient to balance the resistance.

3. On sections where curves largely predominate over tangents it is particularly desirable to have ample compensation, and if excessive, it will do least harm.

4. On sections where the amount of curvature is small it is less important to have full compensation, and if excessive it will do most harm.

5. When the rate of compensation can only be increased at the certain cost of a corresponding increase in the rate of tangent grades (making very sure that it is certain, and not an over-hasty conclusion from inexperience or lack of care), no larger rate than we feel practically certain will be required to balance the curve resistance (0.03 to 0.04) should be chosen. Otherwise, we are committing the folly of making a certain addition to the grade in one place, to avoid one in another place which is merely problematical.

6. On any minor gradients where the curvature is not sufficient to bring the virtual profile up to the maximum it is not important to compensate for curvature at all, although it is generally as well to do so, especially at points where to do so will slightly reduce the cost of construction, as is very apt to be the case on long curves. When not compensated, the curvature merely has an equivalent effect to a slight undulation of gradient, which produces no shock to the train and so is not a measurable disadvantage.

7. It is not in the least essential or important to precisely adapt the compensation to the exact length of each curve. The reduced rate may as well as not begin and end at the nearest even station, and may be made a little less on one curve and a little more on one immediately above if a horizontal slice of a foot or more may thereby be taken off a high fill on the tangent connecting them, but never so as to cause the grade to rise above the uniform grade line.

8. Curves immediately below a known stopping place for all trains need not and should not be compensated at all.

9. The rate of compensation should be uniform per degree for all degrees of curvature, or in no case made greater for the sharper curves. It may even be made less for curves of over 10 deg. If the rate be reduced one-half for the excess over 10 deg., making the compensation for a 16 deg. curve thirteen times that for a 1 deg. curve, it will certainly lead to no bad results, although a rather rough rule. This is directly contrary to the usual practice, which is to increase the rate of compensation with the sharpness of the curve, if anything; but this practice rests upon the assumption (which is the direct contrary of the truth) that the curve resistance increases with the degree of the curve. The results of experience on the New York elevated lines and numerous others with very sharp curves, both of standard and narrow gauge, is enough to disprove this, confirmed as it is very directly by the indications of theory.

10. Since there is no reason to believe that curve resistance increases per ton with the length of the train, or even (appreciably) with the type of engine, there is no reason for varying the compensation because of the grades or length of train, except that it is usually easier to spare the elevation for a liberal rate of compensation, with low grades than with high ones. It is, therefore, proper to do so.

This author states as follows in his "Field Practice of Railway Location" (1909):

"In laying the grade line on the location profile, the rate of maximum grade per station must be reduced by such an amount as necessary to compensate for resistance due to curvature. The reduction in gradient formerly[*] was 0.05 ft. per station of 100 ft. for each degree of curvature. If the maximum gradient was 1%, then a 20 deg. curve would have to be level. As this rate was established by trial of locomotives it varied on different roads. Shunk's formula for equating gradient for curvature was: Degree of curvature (squared) + 10 times degree of curvature ÷ 500. This gives the reduction in grade per 100 ft. and gives an 18 deg. curve as being level when the maximum grade is 1%[†]. The amount of curvature, 5 deg. and flatter, that exists in America on unreduced maximum gradients is enormous. The equating of curvature remains in use as it is based on observed fact."

In his "Curves of Civil Engineering" (1903), this author gives a table of compensation for curves on maximum grades, in which the rate of compensation per degree decreases from 0.03% for a 1 deg. curve to 0.02% for 20 deg. The total compensation then ranges from 0.03% for 1 deg. to 0.1% for 3½ deg., 0.2% for 8 deg., 0.34% for 15 deg. and 0.4% for 20 deg. This idea of decrease in rate of compensation with increase in degree of curve is suggested by Wellington and also later by Raymond and Webb (as noted below), while some writers have advocated an increase in rate of compensation with the increase in degree of curve. On this subject Mr. Haynes states his views as follows:

"When laying a maximum grade or where uniform resistance is desired, the rate of grade should be made less on curves than on tangents by the amounts shown in the table [noted above.—Editor.]. In the lower portions of a maximum grade, where high velocities are admissible and can be had, compensation for curvature is unnecessary. But where the velocity may fall to 8 m.p.h., curve resistance should be compensated fully in the grade so that the resistance and velocity will be uniform. If the velocity drops so that the centrifugal force is lost, the train stalls. A maximum grade in a district is not necessarily one of maximum ratio, but one which produces a maximum tractive power, where curves and velocity are considered."

From "Railroad Location Surveys and Estimates" (1906), we take the following extracts relative to grade compensation on curves, but omitting portions which relate to the ultimate effect of such compensation upon the profile and the operating conditions:

As the resistance to the passage of trains is greater on curves than on tangents, this varying directly with the degree of curve (or, in other words, with the radius), the ruling grade used on tangents must be lessened on the curves, so that the combined resistance due to the curve and the grade on the curve will not be greater than the resistance of the grade alone on the tangents.

Owing to varying conditions of track and rolling stock, the compensation necessary cannot be determined exactly, but is ordinarily assumed to be about 0.04% per degree of curve; that is to say, with a maximum grade of 0.6% on tangents a 4 deg. curve, for instance, should not have a heavier grade than 0.6 — (4.0 × 0.04) = 0.44%. The amount of compensation for curvature is assumed usually to be the same per degree for any degree of curve; thus, if it be assumed at 0.04% per degree, a 1 deg. curve would be compensated 0.04 per station and a 6 deg. curve 0.24 per station. It is generally conceded, however, that the resistance due to curvature does not increase proportionately as the degree of curve, and the writer prefers to use a sliding scale somewhat as follows: Curves up to 2 deg., 0.6% per degree; 0.05 × to 4 deg., 0.04% to 8 deg. and 0.03% per degree to 14 deg. This is intended only as an approximation and suggestion.

The proper amount of compensation for curves is a matter on which opinions vary, and which varies with the state of the track, type of engines, etc. Where curves are few, and, therefore, probably of large radius, the compensation can be increased to as much as 0.1 % per degree, with little probability of increasing the cost of construction, and any error surely will be on the right side. On long ascents, where often every inch counts, and where often a high rate of compensation will mean a higher rate of grade on tangents, or a much longer line, compensation as low as 0.03% for all curves will probably be sufficient. It will be seen that a most important point in locating long lines on ruling grades is the avoidance of curvature as far as possible. More curvature means less rate of grade and, therefore, longer line.

---

[*] The same statement is made in the 1906 edition of Mr. Beahan's book, but he does not explain what period is referred to by the term "formerly."

[†] See quotation further on from a modern edition of Shunk's field book.

Where possible, grades should always be compensated for curvature, whether they are maximum grades or not; provided, however, that such compensation of grades is less than the maximum does not unduly affect the cost. The ideal line from the operative standpoint, as regards fuel economy, and to a certain extent the wear and tear on rolling stock, is one where the differences in resistance due to varying curves and rates of grades are reduced to a minimum. In other words, where, with a constant head of steam, the throttle can be set at a certain point and the train will pull just the same all the way. [For momentum grades] curvature on the maximum grade, when this is greater than the ruling grade, must, of course, be compensated the same as elsewhere, though probably a little more liberally; and in calculating the length of the momentum grades the entire resistance of the curvature must be taken into consideration.

Compensation for curves should be from the nearest even station to the ends, and where spirals or easements are introduced this may generally be from the ends of the true curve (that is, the true curve from the offset points, including the whole central angle), except where the spirals may be very long and then an average rate for the spiral may be introduced.

The subject was under discussion some ten years ago in Engineering News, and in the issue of September 5th, 1901, Mr. Merriam stated his opinion as follows:

"The compensation for curvature should be on a sliding scale, beginning with about 0.04%, or 0.03% per degree, and decreasing as the degree of curvature increases. All the experimental data I have been able to gather confirm this conclusion, but as the condition of the rail with regard to wear enters so largely into this proposition, the results do not point to any definite formula for compensation. The general tendency of modern practice is in the direction of lower compensation all along the line, one prominent western road with easy curves uses only 0.02% per degree."

In commenting upon this, J. L. Campbell stated that he thought it rather doubtful practice to adopt lower rates of compensation on sharp curves, for, while they will give a lower resistance per degree when new rails are laid, the [illegible] through greater wear, more nearly proportional to the degree of curve. He con- [illegible] elevation [illegible] However, as noted [illegible] the views in favor of lower rates for sharper curves. Following up this [illegible]

"[illegible] trains which barely maintained speed on maximum grades on tangent, gained speed on curves; all curves had the same compensation, and more speed was gained on 6 deg. curves than on 2 deg. curves. I have never had the opportunity to measure the resistance due to curvature, but believe the observations above mentioned were carefully taken. They were repeated a number of times and were confirmed by the trainmen operating on the districts where the most curvature existed.

"The condition of the rail is of such importance in this connection that it will be well to state that the rail was new when the above observations were made. The rapid wear of rails would seem to be an argument against the position stated by me in 1901, but Wellington's conclusions regarding rail wear indicate a wear proportional to the degree of curvature. This being true, the increase in surface of contact would be less, after a short time, in sharp curves than in easy curves. Rail maintenance would seem to be one of the conditions required to be known before the rate of compensation can be fixed for any given line, and as this is very hard to forecast, I am using 0.03% in my own practice."

The following is from "Elements of Railroad Engineering" (1909):

"It is customary to offset curve resistance on heavy grades, and on all grades where the combination of curve resistances and grade resistance would more than equal the grade resistance of the ruling grade of the road or division, by reducing the grade. On a crooked road of light grades, curve compensation is impracticable, the curves being in effect the ruling grades. The usual allowance is 0.04 to 0.05% per degree of curvature. But it is thought that on good track 0.025% will be sufficient for 5 deg. curves. The compensation, however, should vary with the degree of curve, and the following values are suggested: 1 deg., 0.04%; 2 to 4 deg., 0.03%; 5 deg. and over, 0.025%. When there is no necessity to save in gradient, full compensation (even up to 0.05%) can do no harm. With poor track and badly curved rails, compensation should be high."

A formula given by Shunk has been mentioned already (in the quotation from W. Beahan), but we do not find this in the 1902 edition of Shunk's "Field Engineer." The subject of grade compensation for curvature is there covered by the following statement favoring a high degree of compensation:

"It is a good custom, and one which cannot prudently be neglected where long stretches of maximum gradient are encountered, to 'slacken grade' on the curves. Opinions differ as to the right allowance per degree of curvature, and no experiments seem to have been made from which to deduce an authoritative rule. Some say 0.025% per degree; others, 0.05; others, variously between the two. Probably 0.05 is the safer rate. This amounts to 2.64 ft. on a mile of continuous 1 deg. curve, and makes a 9 deg. curve about the curve of double resistance at ordinary passenger speeds."

The following extract is from "Railway Track and Track Work" (1908), and is accompanied by figures of the practice on several railways (see Table 1), showing that at that time the ordinary rate was 0.03 to 0.04%, with special rates near stopping places, and sometimes a special compensation in tunnels (to offset decreased adhesion due to damp or slippery rails):

"When curves occur on heavy grades, the grade should be so reduced that the combined train resistance due to grade and curve will not exceed that due to the maximum grade allowed on the tangent. This reduction is taken variously at 0.03 to 0.05% per degree of curve. Thus, with a maximum grade of [illegible] on tangent, and a rate of compensation of [illegible], the maximum grade on a 6 deg.

curve would be 4.76°. The amount of elevation lost by compensating the grade is found by multiplying the degree of central angle of the curve by the rate of compensation; and this elevation divided by the length of grade will give the rate by which the maximum grade on tangent must be increased to avoid a final loss in elevation.

"The change in grade may commence at the nearest even station, and not necessarily at the P.C. The reduced grade extends usually beyond the curve. To avoid too great a loss in elevation or too heavy a grade on the tangent, it may be necessary to modify the rate of compensation, but this will depend largely upon traffic conditions. In general, the compensation should be introduced even upon easy grades, especially those which approach the rate of ruling grade, in order to provide for future increase in train loads or reductions in grades. For curves of 10 deg. or over, the rate of compensation may be reduced (as curve resistance does not increase with the degree of curve). There is a great diversity of practice which is based largely upon opinion and experience, and there is much need for careful experiments in order to give some definite knowledge as to the requirements under modern conditions of rolling-stock and traffic."

The following quotation is from Webb's "Railway Construction" (1909):

On minor grades the addition [of resistance due to curvature] is of little importance, but when the grade is nearly or quite the ruling grade of the road, then the additional resistance induced by a curve will make that curve a place of maximum resistance, and the real maximum will be a virtual grade somewhat higher than the nominal maximum.

The proper rate of compensation evidently is the rate of grade of which the resistance just equals the resistance due to the curve. But such resistance is variable. It is greater as the velocity is lower; it is generally about 2 lb. per ton (equal to a grade of 0.1%) per degree of curve when starting a train. On this account the compensation for a curve which occurs at a known stopping place for the heaviest trains should be 0.1% per degree of curve. The resistance is not even strictly proportioned to the degree of curvature, although it is usually considered to be so. On this account the compensation per degree of curve may be made less on a sharp curve than on an easy curve. The compensation actually required for very fast trains is less than for slow trains, say 0.02 or 0.03% per degree of curve. But since the comparatively slow and heavy freight trains are the trains which are chiefly limited by the ruling grade, the compensation would be made with respect to those trains. From 0.04 to 0.05% per degree is the rate of compensation most usually employed for average conditions.

1. On the upper side of a stopping place for the heaviest trains, compensate 0.10% per degree of curvature.

2. On the lower side of such a stopping place do not compensate at all.

3. Ordinarily compensate about 0.05% per degree of curve.

4. Reduce this rate to 0.04 or even 0.03% if the grade on tangents must be increased to reach the required summit.

5. Reduce the rate somewhat for curvature above 8 or 10 deg.

6. Curves on minor grades need not be compensated, unless the minor grade is so heavy that the added resistance of the curve would make the total resistance greater than that of the ruling grade, or unless there is some ground to believe that the ruling grade may be reduced some time below that of the minor grade under consideration.

The American Railway Engineering Association, through its standing committees, has given a considerable amount of attention to this subject. It is to be noted that the committees which have reported upon it have been of a rather exceptionally high character as to the members and their work, and for this reason their statements deserve careful consideration. Extracts from the several reports, covering practically all that is said on this particular subject, are given below:

1901—In connection with a complete change of location or a modification of the existing location, the maximum grade and curvature should be decided and the necessary compensation calculated for the curves, to make the resistance on curves equal to that on a straight line. On lines where tests have been carried out on an extensive scale, it has been found that it is good practice to use 0.03% for each degree of curvature for all curves up to and including 2 deg., and 0.04% above that to 4 deg. (Committee on Grading.)

1902—From the result of the committee's inquiries it would seem that the practice in this country at present favors compensation proportioned to degree of curve, and 0.04% per degree represents average practice. The observation of the effect of compensation, however, seems on the whole not to have been critical enough to determine definitely whether or not it should be proportional to the degree of curve, and further experiment and critical observation are needed. The effect of curves, as shown on a speed recorder capable of recording slight changes in speed, is suggested as a desirable method of experimenting. (Committee on Roadway.)

1907—Curve resistance is estimated by different engineers at different values. The compilation made by the Committee on Roadway (1902), showed that 0.8 lb. per ton per degree on central angle, or 0.04% for compensation per degree, well represented average practice. (Committee on Economics of Railway Location.)

1908—An inquiry was made by the above committee as to whether any experiments had been made in recent years which confirm or modify the commonly accepted value of 0.04% per degree of curve as the rate of compensation for curvature. Although independent experimental work was referred to, many of the answers merely stated the practice regarding curve compensation. There was a remarkable amount of unanimity in saying that 0.04% was a little higher than necessary, that 0.03% was too small and that 0.035% seemed the proper figure. The variations ranged from 0.02 to 0.08%. In investigating the accuracy of allowance for compensation, the widening of gauge on curves should be tested.

1910—We are interested in curve resistance chiefly from the standpoint of its compensation. In the location of a railway, curvature evils may be eliminated partially by reducing grade on the curve by such an amount as to make the engine effort the same on curve as on tangent. Tests made on the Baltimore & Ohio R.R. (1904), show that on the portion compensated 0.03%, the resistance on curve was greater than on tangent, and on the portion compensated 0.04% the resistance on curve was less than on tangent. In replies to a circular sent out in 1907, the consensus of opinion was that 0.035% per degree gave the best results. (Committee on Economics of Railway Location.)

The committee's recommendation, as adopted by the association, reads: "In order to equalize resistance on curve and tangent, curves ordinarily should be compensated 0.035% per degree of curvature. The effect of curve resistance is dispelled more slowly at slow speed than at high speed."

In the discussion, some of the speakers proposed to substitute 0.04%. Further it was pointed out (following the Wellington line of reasoning) that the rate of compensation should never be made absolutely constant, as the effect of the compensation on construction and on the ruling grade should be taken into account. In some places a high rate of compensation can be introduced without harm; but in other cases the rate has an important influence upon the cost of construction. To adopt as standard a rate that is excessive for average conditions means waste of money and improper compensation. It was with this idea also that the meeting added the word "ordinarily" to the recommendation as originally formulated. It was suggested also in the discussion that on a line built exclusively for freight service, and having curves superelevated for low speed, 0.03% will be too much. The committee's report was accompanied by a table representing actual practice on different roads. This is given herewith, supplemented by figures from Tratman's "Railway Track and Track Work."

Railway Practice as to Grade Compensation for Curves.

N. Y., N.H. & H.	0.03 too light, 0.04 too heavy.
B. & O.	0.03 too light, 0.04 too heavy.
So. Pac. (At. Sys.)	0.03 too light, 0.04 too heavy.
*No. Pac.	0.03 too light; 0.04 fairly good results (not quite enough with curves frequently changing direction, slightly in excess for long continuous curves).
C., R. I. & P.	On 0.03 (with new rail) trains retarded at less than 10 m.p.h. and accelerated at higher velocities.
G. T. Pacific	0.04 too high for new rail.
N. Y. Central	0.03 made limiting grades on curves; 0.04 satisfactory.
*C., M. & St. P.	0.035 generally on maximum grades; sometimes 0.03.
P. & L. E.	0.035 satisfactory.
[illegible]	[illegible] satisfactory.
N. & W.	0.035 satisfactory; trains accelerate on 0.04.
Car., C. & O.	Trains loaded for 1% grade accelerate on curves compensated 0.035.
*L. & N.	0.03 too low; 0.05 to be used.
W. & L. E.	0.03 used, but 0.04 preferred.
Can. Pac.	0.04 satisfactory up to 5°; too high for sharper curves.
Wes. Pac.	0.04 used, but probably higher than necessary.
Wash. & Ore.	Trains stalled or retarded on 0.04; 0.05 satisfactory. On 0.05 trains loaded for 10 m.p.h. on ruling grade tangents retarded; trains for 15 m.p.h. accelerated.
*Ill. Cen.	0.04. On Ind. So., 0.04 when curve [illegible] at maximum train, 0.03 when not more than half as long as train.
[illegible]	[illegible]

A LOCK TIE BRICK COMPANY.

A new corporation, the Lock Tie Brick Company, of [illegible] has been organized by [illegible] Securities Agencies, and among the directors are Mr. J. B. [illegible], Evans, Coleman and Evans, Limited, and Mr. H. J. N. [illegible]

THE DISPOSAL OF SEWAGE SLUDGE.

Of the many difficult problems which the sewerage engineer is called upon to solve none gives him more anxiety than the one connected with the satisfactory disposal of sludge. In a paper read before the Royal Sanitary Institute Congress at York, England, Mr. Arthur Hindle and P. Holt Whitaker gave one solution of the sludge problem. The authors state that, in common with other engineers who are called upon to advise local authorities as to their sanitary arrangements, they have been faced with this difficulty, and at some sewage disposal works recently carried out under their guidance have installed a system of treating the sludge which has proved so efficient as to justify them in giving a brief description thereof in the hope that it may be of some interest to their professional colleagues. The system referred to was provided at the sewage disposal works which the authors designed and carried out for the Penrith Urban District Council.

Penrith is a market town in Cumberland, and has a population according to the last census of 8,993. There are no works or manufactories beyond two small breweries, so that, with this exception, the sewage is purely domestic. The original sewerage works for Penrith were carried out in the year 1850, and comprised a system of main sewers and sewage disposal works on the broad irrigation system on a large area of land known as Westmorland Holme, situate near Eamont Bridge, about one mile from the centre of the town. The new works, which are now practically completed, comprise an entirely new system of main and subsidiary sewers throughout the town, an outfall sewer about 2½ miles in length, including crossing of the River Eamont, which was done by means of a gravitating cast-iron pipe carried by a lattice girder bridge of 120 ft. span, and sewage disposal works on lands forming part of Whinfell Holme, which were acquired from Lord Hothfield, the price being fixed by arbitration. An area of 25 acres was acquired, but only about 12 acres have as yet been laid out. The subsoil is eminently suitable for filtration purposes, consisting of a deep bed of gravel, which is overlaid with about 2 ft. of fibrous soil.

The sewage treatment consists of sedimentation in tanks and filtration through land on the intermittent downward principle. There are four circular sedimentation tanks, each 40 ft. in diameter and an average of 7 ft. 6 in. deep, so arranged as to enable them to be worked on the quiescent or continuous-flow principle, either separately or in series, as circumstances dictate. Inlet and outlet channels, junction wells and controlling valves are provided. Before entering the tanks, the sewage passes through screening chambers, which are arranged in duplicate and fitted with Stott's revolving screens. Between the screening chamber and the mixing buildings there is a dividing well, whence the storm water flows to specially prepared areas. Three times the dry-weather flow passes to the works for full treatment, and three times passes to the storm water beds. The buildings comprise mixing-house, small engine-house, with oil engine and pump, store-room, and office. Up to the present time it has not been found necessary to use any precipitants, but arrangements are made in the mixing-house therefor should their use ever be required.

After leaving the tanks the effluent passes over aeration weirs, thence into a main carrier, and is subsequently distributed by means of subsidiary carriers over the land filtration areas, which are underdrained with [illegible] in agricultural tiles, the number depending upon the nature of the subsoil in each area, and these in turn are connected to a main effluent drain, which discharges the purified effluent into the River Eamont, a well-known fishing river.

The levels of the outfall site were such as did not permit of the sludge being drawn off from the bottom of the tanks so as to gravitate to the sludge drying-beds. It was, therefore, necessary to provide some means of lifting it to the desired level, without, if possible, incurring the cost of pumping. This was accomplished by utilizing the head of the water in the tanks for the purpose of forcing the resultant sludge to the drying-beds, and to assist in this object an apparatus known as Fidler's revolving scraper was placed in each sedimentation tank.

The Fidler scraper arrangement is intended to facilitate the removal of sludge without interfering with the continuous working of the sedimentation tanks and to deliver the sludge at a level only a few inches below the top water level of the tank. The scraper, by means of which the sludge is directed to a sump in the bottom of the sedimentation tanks, is helical in form; it is attached to and supported from a lattice girder, and is rotated by gearing fixed at the side of the tank adjacent to a sludge discharge chamber so as to give opportunity for careful regulation of the discharge. When it is desired to remove the sludge the scraper is revolved and the sludge directed into the central sump, from the bottom of which it is forced to the sludge drying-beds. Valves are provided on the several pipes to regulate and control the flow.

The sludge drying-beds are four in number, each 25 ft. long by 10 ft. by 6 ft. deep; they are constructed of brickwork, backed on the outer side with concrete; the floors are made of concrete, laid with proper falls in the direction of the drains. Each bed is provided with doors, constructed in sections, extending the full width of the bed at the lower end, which can be raised or lowered at will as the material in the beds increases or decreases. Cross walls are formed of perforated boards laid in grooves so as to be easily adjusted.

When the sludge is about to be emptied from the sedimentation tanks, a layer of straw, litter, dried weeds or the like is first laid in each tank or compartment in such a manner that the whole surface of the bed is covered; the litter is also drawn slightly up the sides of the beds or compartments, as well as round the vertical perforated pipes or shafts. These perforated vertical pipes are about 6 in. in diameter, in lengths of about 2 ft., provided with sockets and spigots, so that they can be built up in continuous shafts from the floor to the top of the bed as it is being filled. A layer of sludge, to the depth of 4 in. to 6 in., is then run on to the litter, which acts as a filter, the litter allowing the liquid to filter through and find its way to the perforated pipes, which in turn are connected to drains laid on the floor of the beds. This operation of filling the beds alternately with litter and sludge is repeated until the bed or compartment is filled, when operations are transferred to the next bed. The liquor draining from the sludge beds is conveyed to a well, and is then pumped, by the oil engine and pump previously referred to, into the feed channel of the tanks for re-treatment. As the beds are being filled the increasing weight compresses the sludge and litter, thus forming, after proper settlement, a firm bed of manure, which is easily handled and is very portable. A layer of litter is always placed on the top of a layer of sludge to obviate any nuisance from smell, which one usually expects to arise from open sludge beds or lagoons.

The authors were assisted by the Surveyor to the Penrith Urban District Council, Mr. J. J. Knewstubb (member), who acted as resident engineer throughout the construction of the sewerage works, and who has supplied, for the purpose of this paper, the following information:—

Population dealt with in the scheme, 8,000.

Daily dry-weather flow per twenty-four hours, 290,000 gallons.

Quantity of wet sludge passed on to the beds per day, 2½ tons average.

Quantity of dried sludge taken out of the beds per day, 16 cwt. average.

Quantity of dried sludge removed from the beds and sold per annum, about 300 tons, average.

Quantity of litter used in the beds per year, 70 tons.

Length of time occupied in drying the wet sludge; this varies according to the season, but averages about six weeks.

Length of time occupied in filling one bed, about four weeks. This again varies according to the time of the year and atmospheric conditions.

Rate of consolidation varies according to depth of bed.

Length of time required for the dried sludge to attain its most beneficial condition as manure after removal from the beds, twelve months.

The sludge is sold by open tender every year, and the average price per cart load realized has been 1s. 9d. per load. The authors are informed that the manure removed from the sludge beds after treatment under this system is most beneficial for use on land growing turnips and mangolds, and also gives good results for clover and seed grass at any time and under almost any conditions. It has also been found to be an excellent material for ploughing into land of a light character.

No additional expense is placed upon the Council in dealing with the sludge, as the operation of filling the beds is performed by one of the regular men employed on the farm, and occupies but an infinitesimal portion of his time. The emptying of the beds is undertaken by, and at the expense of, the purchaser of the dried sludge, who also provides and brings to the beds part of the litter required; this, of course, being a consideration of the purchase price. So far as Penrith is concerned the sludge problem has been solved; the authors have, however, up to now hesitated to supply any description of the system, as they were desirous it should have a fair and ample trial before doing so.

This description is given purely from an engineer's point of view, apart from that of the chemist. There is, however, the practical side of the question in that the farmers of the district are competitors for the dried material. The works were completed in the latter part of 1907, were formally opened on, and have been in continuous operation since, the 19th of March, 1908.

◆

CANADA'S COOPERAGE INDUSTRY.

Seven million two hundred and ninety-three thousand oak staves were imported into Canada during 1911, while only 2,768,000 were cut in the Dominion. These figures which show that Canada is fast losing her possibilities as a producer of tight cooperage, are contained in a bulletin issued by the forestry branch of the department of the interior.

In the manufacture of slack cooperage, used for the dry rough commodities such as lime, potatoes, apples, dry fish, flour, cereals, etc., which predominate in Canada's products, elm is the principal wood employed, forming over 50 per cent. of the total consumption. Spruce is rapidly coming into more general use as a source of stave supply, eleven million more spruce staves and nine million fewer elm staves having been used in 1911 than in 1910. When elm is exhausted birch will probably take its place, being comparatively flexible and available in great quantity.

The total value of the materials used in the slack cooperage industry in Canada for the past year was $1,465,702. In 1910 it was $1,595,119 or some $130,000 more. Imports and exports of materials and finished product were, respectively, $329,992 and $135,463, an excess of imports over exports of $194,529.

THE CYLINDER PERFORMANCE OF RECIPROCATING STEAM ENGINES.

In the report of an investigation by Mr. J. Paul Clayton, printed in the Journal of the American Society of Mechanical Engineers, April, 1912, the author states that it has been found that the indicator diagram contains in itself the evidence necessary for an almost complete analysis of cylinder performance, the results of which have not heretofore been considered possible. In obtaining these results the pressure and volume values of the indicator diagram have been plotted on logarithmic cross-section paper; and by the aid of this logarithmic diagram it has been found that the expansion and compression curves of all elastic media used in practice obey substantially the polytropic law $PV^n = C$. From this and other discovered facts the author has developed rational methods of closely approximating the clearance of a cylinder, of locating the cyclic events, of detecting moderate leakage, and of determining the actual steam consumption of the engine.

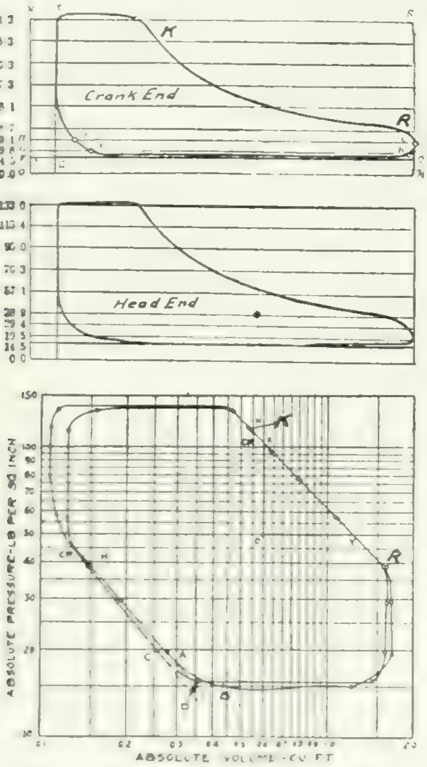

Fig. 1.—Construction of the Logarithmic Indicator Diagram.

Construction of the Logarithmic Diagram.—Fig. 1, in its upper half, shows the indicator diagrams taken from both ends of a 12 x 24-in. single-cylinder Corliss engine used in the tests; ON is the line of zero pressure, OM the line of zero volume, and FQ the atmospheric line. The clearance is 7.04%, and is represented by FE. Horizontal lines are ruled over the diagram, at known pressures, as shown. Thus, absolute pressure at K = 115.3 lb., and at R = 38.7 lb.; absolute cylinder volume at K, measured from the line MO = 0.521 cu. ft., and at R = 1.572 cu. ft. These values are plotted as shown in the lower diagram and the procedure is the same for all other points in each indicator diagram.

[illegible]

Rational Method of Approximating Clearance.—When [illegible] the expansion and compression lines in the logarithmic diagram are straight lines. When the value assumed for the clearance volume is greater or less than the true value, these lines are curved. Fig. 2 gives logarithmic plottings of an indicator diagram taken from a 42 x 60-in. gas engine, the clearance being assumed successively at 14, 16, 18, 20 and 22%. The approximately straight line for the value of 18% is the transition between the two families of curves bending to the left and right, as shown, and the true value of the clearance is therefore very close to 18%. All that is necessary, therefore, is to assume different values for the clearance, plot and logarithmic diagram for each value and determine the straight-line value by trial and error. This may be found to within 5 to 10% of the true value, depending as the clearance itself varies from 20% to 2%, respectively, of the piston displacement.

Locating the Stroke Position of Cyclic Events.—For ordinary purposes these can generally be located by inspection of indicator diagrams themselves; thus cut-offs may be generally located on a Corliss engine diagram to within 1/16 in. measured along its length. The actual beginning of true compression, however, can never be accurately located on the PV-diagram. True compression, unaffected by leakage, begins after the exhaust valve, in closing, has acquired enough seal to prevent leakage; its point of beginning is generally at least 5 lb. above the back pressure. The point at which leakage ceases cannot be located on the PV-diagram because the curve of true compression, and the curve during the time the valve has insufficient seal, are of the same direction of curvature, and are not reverse curves as in the general case of admission and expansion.

As expansion and compression of a constant weight of medium take place according to the law $PV^n = C$ and are indicated by straight lines in the logarithmic diagram, it becomes easy to locate thereon the events of cut-off, release, compression and lead by noting when the expansion and compression lines become straight. These events, though obscure in the PV-diagram, may be located to well within 1/16 in. in the logarithmic diagram, which is equivalent to about [illegible] in. when retransferred to the PV-diagram. [illegible] These methods largely eliminate the variable element of personal judgment. The upper part of Fig. [illegible] shows cards taken from a [illegible] superheated steam locomotive running at [illegible] and high speed. Below these cards are plotted in the form of logarithmic diagrams, showing how the cyclic events may be readily located.

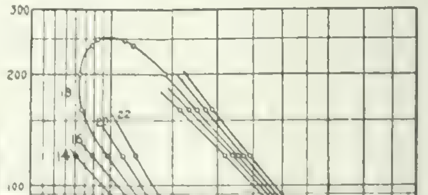

Fig. 2.—Determination of Clearance by the Logarithmic Diagram.

The Detection of Leakage.—The law $PV^n = C$ applies only in cases where the weight of the working medium remains practically constant during any expansion or compression. When this weight changes materially, either by leakage into, or out from, the cylinder, the resulting expansion or compression no longer obeys the law and it becomes a curve on the logarithmic diagram. Leakage is usually the result of wear, and occurs, as a rule, only when the pressure difference is over about 20 lb. This latter fact, founded on the analysis of numerous diagrams, makes it possible to divide the expansion and compression lines roughly into three equal parts on the logarithmic diagram (when these lines extend from the initial pressure nearly to the back pressure): (a) the upper third, influenced by leaks out from the cylinder; (b) the middle third, practically uninfluenced by leakage; and (c) the lower third, influenced by leakage into the cylinder. Thus, fairly reliable values of n, free from the effect of leakage, may be obtained from the middle third. The important result attained by this method of examination is the knowledge that leakage is taking place, so that it can be located and stopped.

The Approximate Determination of Steam Consumption from Indicator Diagrams.—The devising of an accurate method of measuring the weight of steam consumed from the diagram has hitherto been regarded as impossible, but, after many examinations into the cases of different types and sizes of engines, with non-jacketed cylinders in good order with pressures between 60 and 120 lb. absolute, and exhausting at or near atmospheric pressures, it has been found that while the initial condensation is subject to the action of ten or more variables, yet the value often resulting from a given value of Xc (or proportion of the total weight of steam mixture present as steam at cut-off, i.e., quality) is almost always substantially the same, and is expressed by the relation $Xc = 1.245n - 0.576$.

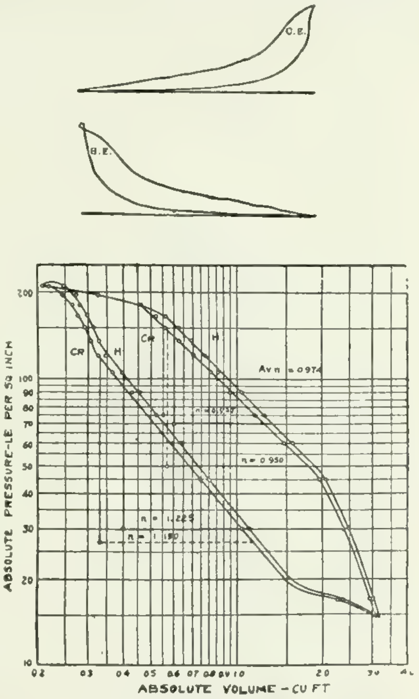

Fig. 3.—Locating the Stroke Position of Cyclic Events.

This relation is practically independent of cylinder size and of engine speed. The point of cut-off and the value of n being obtained from the logarithmic diagram, the value of Xc may be readily calculated and the actual steam consumption obtained by this method to well within 4% (on the average) of the amount consumed as measured by test.

This method is more accurate than the average test; it is the only accurate method available for testing certain classes of engines; it virtually measures an instantaneous rate instead of an average quantity over a long period, and thus enables a large number of points to be obtained for a water-rate curve; it permits of making tests at frequent intervals instead of once in the engine's life; the expense is not to be compared with that of an equally accurate test; it involves in the routine of the plant tested.

THE STRENGTH OF WOOD FOR PAVEMENTS.

The wood pavements in Paris, France, last on an average nine years, but in the most frequented roads they have to be renewed every five or six years. This rapid wear has led to the undertaking of various experiments in the Municipal Testing Laboratory in an effort to find means for increasing the strength and at the same time the durability of the materials for wood pavements. The following description of these experiments and the resulting conclusions are taken from a paper of M. P. Labordere, Engineer of Bridges and Roads, and M. F. Austett, Director of the Municipal Testing Laboratory of Paris, prepared for presentation at the Sixth Congress of the International Association for Testing Materials:

Up to the present time the only treatment to which the woods used in Paris are subjected has the aim of diminishing decay. It consists in impregnating the newly cut blocks with a heavy coal tar oil which is rich in phenols; this impregnation is as a rule simply effected by means of immersion. The Municipal Testing Laboratory, however, has for some years been occupied with securing some better impregnation by making the heavy oil enter the wood under a pressure of 5 kg. The first series of experiments which was executed in the laboratory in 1908 and 1909 brought out the conclusion that the impregnation with heavy oil under pressure improves the wood as regards the physical qualities, because it diminishes the porosity of the blocks (that is to say, the quantity of water which is capable of being absorbed by the wood after immersion), as well as their expansion under the influence of moisture, but that it remains without effect on the mechanical strength of the wood.

In order to compare the mechanical strengths of wood prepared in different manners the pressure per square centimetre which enacted in the direction of the fibres will produce crushing was adopted as a measure of this strength. The specimens used in these experiments were prisms of 75 x 75 mm. basis and 125 mm. height, and they were obtained by cutting three equal specimens out of each of the blocks, the blocks serving for the experiments being 240 x 80 x 120 mm. Care was taken to keep the different blocks employed for these experiments apart from one another, to number the blocks of each balk from one end to the other, and to mark each of the specimens cut out of each block in such a way that the specimens belonging to the same fife reckoned in the longitudinal direction of the balk could be compared. The different blocks of one and the same balk were submitted to different treatments, and the specimens cut out of these blocks were crushed in the hydraulic press.

The determination of the crushing strength does not offer any difficulties; for in the moment at which the specimen fails the pressure gage of the machine will mark a sudden fall. In order to take account of the effect of humidity which cannot be avoided on the roads, care was taken in each case to experiment on two specimens in the dry state, and on a third specimen which had been immersed in water for 30 days.

As the length of the longest balks, which the laboratory had at its disposal, 2.30 m., does not permit of cutting more than 18 blocks (or 18 comparable specimens), and as moreover the number of methods of preparing the specimen for the test was greater than 18, it was necessary to agree upon a reference basis for all these experiments. This standard was taken as the strength of an ordinary crude block and consequently in each balk two blocks at least were reserved which were left in the crude state and sawn into two specimens to be crushed in this state.

Attention having been drawn to various attempts of improving the wooden pavements by mixing the oil, with which they were to be injected, with alkaline carbonates and silicates, a study was made in the experiments of the influence upon the quality of the pine wood of a mixture of the following products:

Pine tar.
Alkaline carbonates (sodium or potassium).
Sodium silicate.

In order to study the conditions of the experiments the temperature of the bath was varied and in a more restricted manner also the proportions of the chemical products applied were varied.

The experimenters used a bath of pure pine tar heated up to 60, 80 or 110° C. They then, at analagous temperatures, made use of pine tar to which one of the following ingredients had been added:

Sodium carbonate......	2 grammes per litre of tar 4 grammes per litre of tar
Sodium silicate	4 grammes per litre of tar

The results obtained did not show any appreciable superiority of the one or the other bath composition.

Raising the temperature of the bath, on the other hand, produced a marked increase (12 per cent.) in the strength of the specimens which had been kept dry; but it had no appreciable effect on specimens which had been preserved in water.

The objection to this process was the high price of the pine tar. Attempts were then made to replace this product by a low price hydrocarbon, and the heavy coal tar oil which is used in the works of the city of Paris for impregnating wooden pavements was employed. The impregnation was effected under the same conditions as with the pine tar at temperatures lying between 112 and 140° C. With the highest temperature applied the strengths became the same as with the bath of pine tar, at the lowest temperatures, however, the strength was equal or even inferior to that of the ordinary crude blocks. This showed the possibility of employing the heavy tar oil in the place of a vegetable tar, but only on condition that the temperature of the bath be raised up to something between 115 and 140°, and probably best to 125 or [illegible]°.

As an improvement had been realized by the application of a complex bath (liquid No. 7, heavy oil, sodium carbonate), steps were taken to find the cause of this amelioration, and the experiments were recommenced by adding successively to the heavy oil some carbonate of soda (liquid No. 8) and some silicate of soda (liquid No. 9).

The strengths which, in the case of blocks treated with the mixture of sodium carbonate and silicate, had remained inferior or at the best equal to that of the crude blocks, underwent a sensible increase when the wood was treated alone with carbonate and, more still, when treated alone with the silicate. This result appeared at first decidedly contradictory.

[illegible] trary, decidedly more favorable in the case of balks impregnated at [illegible]

It appears then that, [illegible]

found for the blocks which had been kept in the dry were as follows:

		Mean strength.
Non-treated blocks		323 kg cm²
Temperature of bath	80°	337 "
	90°	347 "
	100°	330 "
	110°	358 "
	120°	345 "
	140°	487 "

Fresh experiments were conducted by heating blocks in baths up to 150 and 200°, care being taken to make the bath simply of tar or heavy oil, in order to verify the correctness of the previous conclusions relative to the usefulness of the mineral constituents.

The temperature of 200° was not exceeded because at that temperature the wood begins to visibly undergo disaggregation. The escape of the constitutional water leads to the production of numerous fissures, parallel to the fibres, which would certainly not be unobjectionable, if it were only on account of the facility which the cracks provide for water to enter into the wooden paving.

The new baths studied gave sensible improvements over those previously applied, as the following figures will show:

Temperature of the bath.	Mean strength.
150°	516 kg/cm²
200°	536 kg/cm²

It was therefore concluded that up to 200°, the limit of temperatures admissible for impregnation baths, a rise in the temperature of the bath will lead to an increase in the strength of the pavement. It appears, however, that, with regard to the improvement of the strength, little would be gained by heating the wood above 130 or 140°. The inconvenient production of cracks or fissures, which allow the water to penetrate from outside, and the heavy expense incurred by heating the wood to very high temperatures would render it advisable to limit the temperature of the bath to these figures.

As a further experiment some wooden blocks were heated in a dry air stove, at the same time that other blocks of the same balks were being heated in a heavy oil. The temperature was the same in the two cases, 200°. There was the increase of the strengths in both cases, though less marked in the former than in the latter. The result was, however, sufficient to put aside the hypothesis of an improvement of the wood simply by the action of the oil. It would therefore appear that the improvement is, to a large extent, at least due to the dehydration of the wood and to a transformation of its fibres wholly owing to the action of heat.

It would moreover appear that experiments conducted a few years ago in America (related in the work of Petsche: Wood, page 272) have established that, after heating wood up to a temperature ranging from 150 to 200° under a pressure of from 10 to 14 kg. per cm. square, a blackish antiseptic mixture is formed which remains imprisoned in the wood and which contains acetic acid, acetone and tarry matter. Should it be these substances which increase the strength of the wood? It would be premature to form more than hypotheses as regards this point.

However that may be, heating in the dry state, such as was employed in the Municipal Laboratory for certain blocks, could not practically be applied, because the blocks of wood heated in the dry would lose their water more rapidly than when heated in oil and would begin to split. At 200° moreover they would undergo a very sensible superficial carbonization. It was, therefore, concluded that it must be the heating in the oil which is the essential thing in improving wood, and for reasons already stated the temperature of the bath should be fixed at 130 or 140°. There remained the question, for how long a period the immersion in the hot bath should be continued.

A pretty long period is forcibly necessary; for the elevation of the temperature must be progressive, lest the humidity contained in the wood should suddenly escape giving rise to fissures. In the French experiments the blocks were always put in the cold oil and the oil heated. In industrial processes this practice might be replaced by the use of several successive baths at increasing temperatures. The length of the heating period which was 10 hours in the first experiments has progressively been reduced to 8, 6 and 3 hours. It is with this last mentioned period of 3 hours that the highest strength was obtained at temperatures lying between 150 and 200°.

Experiments made with heating periods of from 2 to 3½ hours have demonstrated, that up to about 3½ hours an improvement can be noticed which is practically proportional to the length of the heating period. It was, therefore, concluded that it will be advisable to fix the heating period so far as possible at 3 or 3½ hours. The exact determination of this period depends upon the relation between expense and improvement realized, and practice alone can decide this point. The results so far alluded to all concern specimens which had been kept in the dry, although particular precautions were not taken to dry the specimens more than the surrounding air. This condition is very different from that of a wooden pavement laid on a public road, where it is always more or less soaked with water, both by rain and the frequent sprinklings.

In order to meet this later condition all the experiments mentioned above were renewed with specimens kept for 30 days in baths filled with water. Contrary to what had been established with regard to the dry specimens, the experiments yielded under these new conditions much less important results. The investigators concluded that it would therefore be advantageous to prevent the penetration of water into the wood so far as possible, in order to secure all the benefits of the hot treatment. The experiments seemed to demonstrate that to prevent the soaking of the pavement with water, impregnation by immersion and heating even up to high temperatures of 150 or 200° in heavy oil or in tar constitute altogether insufficient remedies. From experiments conducted in 1910 it was concluded that creosoting under pressure, which makes the oil penetrate more deeply into the wood, prevents the invasion of the wood by water. Experiments were therefore conducted by making this treatment at high temperature sometimes precede, and sometimes succeed the impregnation. To further vary the experimental conditions, the heating was effected sometimes in an oil bath, sometimes in a bath of dry air. The experiment seemed to have established that creosoting under pressure combined with heating noticeably improves the strengths of blocks kept dry. But as regards the blocks which had been kept immersed this treatment only resulted in imparting a strength which was about equal to that of the crude block. This was a remarkable fact; for the amount of water which is absorbed by wood is much reduced by creosoting under pressure as is well known. One may therefore declare that it is the first portions of water absorbed after desiccation which play the most injurious part. It might therefore be concluded that creosoting under pressure does not suffice to counteract the detrimental effects of soaking with water.

Efforts were made to find other means for preventing this penetration and experiments were tried with a view to surrounding each block with a superficial protective layer. This layer can easily and economically be obtained by the aid of a pitch or tar analogous to the products which are used in tarring the macadamized roads. It was found that when the wooden blocks, crude or creosoted, and consequently very permeable were simply plunged into hot pitch, there is indeed, formed about them a shiny continuous coating which suffices to keep the water out to a large extent. The increase in the weight of such blocks which have been immersed in water is indeed considerably diminished by this treatment especially when they are left in the pitch for appreciable periods (10 minutes).

When this process of coating with pitch with creosoting by immersion and particularly with creosoting under pressure was concluded altogether remarkable results were obtained. It is, however, particularly a prolonged lying of the wood in pitch which is very efficacious in preventing its invasion by water. When the immersion period lasts a sensible time, the holes, which were formed in the coating of the pitch at the moment of their being soaked by the escape of the water contained in the superficial layers of the block which were exposed to contact with the hot tar, are indeed being closed.

Attempts were made to confirm the conclusion as to the efficacy of pitch by measuring the crushing strengths of specimens which have been cut out of blocks plunged into pitch. But owing to some circumstances which have remained obscure, the results of this experiment were really contradictory. The experiments show for blocks, which were coated with pitch and then immersed in water, sometimes an increased strength and sometimes a decreased strength.

Meanwhile, however, the investigations conclude from the very small quantity of water which penetrates into blocks coated with pitch, and especially in the case of those which remain for 10 minutes in pitch at 110°, that there is some advantage in making them undergo this treatment after heating. In order to simplify the operations it might perhaps be best to heat the blocks in the pitch itself, since the nature of the heating bath does not appear to have any important influence; but it will only be after some more prolonged experiments that the practical applicability of this heating process can be decided upon.

As regards the wear of the protected coating due to the traffic, this can be obviated by proceeding periodically to a superficial tarring of the road, under the same conditions as with macadamized roads.

The experiments show that the tar can be made to enter to depths of several mm. into the wood, when sprinklers at high pressure are applied.

The conclusions arrived at by Messrs. Labordere and Anstett as the results of these experiments are as follows:

From what we have explained we consider that the crushing strengths of wooden paving blocks can considerably be improved by heating in a bath of heavy oil tar at a temperature of 130° or 140°, maintained during a period which may provisorily be fixed at 3 hours, but which further experiments may perhaps permit us to diminish. The heavy oil to be used should be chosen such as does not contain any notable quantities of products which are volatile at 140°.

In order to reduce the diminution in the strengths which is due to the inbibition of the wood paving with water, we may employ, separately or together, the two following processes:

1. Add to the oil bath a small quantity of sodium carbonate and of sodium silicate, which may approximately be fixed at 0.6% for the carbonate and at 0.1% for the silicate.

2. Immerse the blocks after heating and creosoting under pressure in a bath of liquid pitch at 110°, the immersion being kept on for about 10 minutes; then apply superficial tarring of the laid pavement as described above.

The pitch to be used should be half-dry gas pitch including about 10% of anthracene oils.

The second method appears to be of a much superior efficacy. As long as the pavement will remain in good condition the protective layer will not be attacked. The addition of alkaline salt is yet not useless; for it permits of maintaining a certain improvement even in cases where, by consequence of the wear, the blocks should no longer be protected against the infiltration of an appreciable amount of water.

COMMERCIAL UTILIZATION OF PEAT FOR POWER PURPOSES.*

By H. V. Pegg, of Belfast.

The question of the utilization of peat fuel for power purposes has received a large amount of attention from engineers for many years past. Efforts in this direction have mostly taken the shape of some form of preparation of peat fuel in order primarily to get rid of the superabundant moisture in the fuel. Very large sums of money have been spent on peat-preparing machinery with generally very inadequate results, hence it has always appeared to the author that, in order to bring the utilization of peat to a commercial level, the first consideration would be the utilization of the peat as far as possible in the condition in which it leaves the boglands without any preliminary and expensive machine treatment.

The author had the opportunity about seven years ago of experimenting with air-dried hand-cut peat fired into a special form of gas-producer. With all gas-producers using bituminous fuel the main trouble is to get rid of the tarry by-product. In this instance the gas-producer was arranged to work intermittently, there being periods of "blowing" during which the fuel in the producer was urged to incandescence, and periods of gas-making during which the tarry by-products were passed through the incandescent fuel, where they were split up into gas. The chief difficulty experienced with this plant was the high thermal value of the gas generated, about 330 B.Th.U. Owing to the high and varying percentage of hydrogen in the gas, it proved unsuitable for use in the works gas-engine; and although the plant was running more or less continuously for ten days driving the whole works, very considerable trouble was experienced, not only in the engine, but also in the plant, [illegible] the producer plant being decidedly sensitive in regard to this latter [illegible] patents and to the author's specification. This plant, which has been running since last September, has been so often dealt with in the daily and technical press that there is no need for the author to dwell upon the details of the plant, but he proposes to make a few remarks in regard to the difficulties experienced.

Air-dried peat is not a very convenient fuel to fire into the producer, and as it was uncertain whether it would be possible to burn the fuel direct in the form in which it came from the boglands, provision was originally made in the plant to deal with peat fuel prepared by being reduced in size to blocks of about 5 in. cube; but it was found possible to dispense with the preliminary treatment, and the construction of the plant was thereby considerably simplified.

As regards the general running of the plant, last October it was subjected to a test run of six hours' duration with a load of 250 brake horse-power, the peat consumption per brake-horse-power hour averaging 2.55 lb., the peat fuel containing 18.98 per cent. of water; this was with both producers running, although the load was considerably below the total capacity of the plant. When necessary it has been found that the above load can be safely carried with either producer working singly, and the plant has run under these conditions for several days.

It will be noted that the percentage of moisture in the fuel during the above test was unusually low. This was owing to the unusually dry summer of 1911. During November, and especially December, last the fuel fed to the plant was extremely wet, as the rainfall in those months was very heavy and the fuel supply was and is entirely exposed to the weather. The plant, however, worked just as well with sodden peat as it did with the drier peat, the only difference being the amount of fuel consumed. The amount of water in this "sodden peat" varied considerably from day to day, and the exact percentage was not arrived at; as near as could be estimated it was at least 70 per cent.

The separation of the tar from the gas was the chief difficulty to be overcome; it was found far better to rely on an ample watery-spray through which the gas passed rather than any form of a coke-scrubber, as the coke rapidly became clogged with tar. The main portion of the tar was thrown out into a tar-sump by a centrifugal tar-extractor; but unless the gases were subjected to a thorough washing and cooling by the water-spray above referred to, it was found that a certain proportion of tar got past the extractor, collected in the gas-mains, and finally found its way into the gas-engines. It was a matter of experiment as to the precise amount of water sprayed into the cooler which was necessary in order to ensure that the tar vapor should be sufficiently condensed before reaching the centrifugal extractor, so as to enable the extractor to effect the needful separation. As now arranged, the proportion of tar in the gas after passing the extractor is small, and the engine-valves do not want cleaning out more than once a week.

When first started, the plant generally, and especially the producers, required a thorough cleaning once a week; at the present date the plant can be run, if necessary, for three weeks without cleaning, though the weekly cleaning generally takes place as a matter of policy. This result has been obtained owing to the increased amount of washing-water used, which now amounts to about 7 gallons per brake horse-power per hour. The proportion of tar recovered is about [illegible] per cent of the weight of fuel consumed, and during the [illegible] stages of the running of the plant a certain amount of this tar was sold to tar-felt manufacturers at a [illegible] per ton, [illegible] in this direction ceased owing [illegible] odor which per[illegible] not only to the tar itself, but to all the [illegible]

---

* [illegible] Belfast, [illegible]

Experiments have also been made with the tar in oil-burning boilers, but owing to the very high percentage of water in the tar—up to 50 per cent.—and the large quantity of solid matter also present, a very large amount of preliminary treatment is necessary. For a considerable period the tar at Portadown was used mixed with coal and burnt under a Stirling boiler; the precise heating value of the tar so consumed has not, however, been ascertained. At the present time the whole factory at Portadown is run entirely on peat-fuel, the consumption being about 44 tons per week, of which the producer plant takes about 22 tons. The nature of the peat varies considerably; with good black heavy peat the weekly consumption for all purposes drops as low as 35 tons, and with light top peat from the surface of the boglands the consumption rises to 54 tons. It is also interesting to note that the quality of the peat is reflected in the carrying capacity of the barges which bring a load of 35 tons with heavy peat and 24 tons light peat. The peat is unloaded from the barges and conveyed to the producer platform and boiler-house by a transporter. Clinker troubles are not often experienced, and only when burning the inferior grade of peat, the presence of sand in the fuel causing the trouble.

The author is indebted to Mr. W. A. Mullen, manager at the factory of Messrs. Hamilton Robb, Limited, for the following figures in regard to the cost of fuel, these figures being given on June 12 last:—

Cost of Running Factory on Coal Per Week.

	£	s.	d.
8½ tons of anthracite at 35s.	14	17	6
19 tons of steam coal at 17s.	16	3	0
	31	0	6

Cost of Running Factory on Peat Per Week.

	£	s.	d.
Say up to 50 tons of peat at 6s.	15	0	0
Weekly saving	16	0	6

Allowing for 15s. for extra labor, the net weekly saving figures out at £15 5s. 6d.

The author would here refer to the letter in Engineering of January 26 last, in which the general manager of the Power Gas Corporation, Limited, gives some very interesting particulars in regard to peat plants, more especially an ammonia-recovery plant working in the south of England. It would be of great interest if some figures as to the working costs of this plant could be laid before this meeting. It will be noted that plant is worked with ammonia recovery, which would mean a very much larger plant than that at Portadown. The amount of the nitrogen in the South of England peat is apparently high, and would appear to be considerably more than in the peat used at Portadown, analysis of which is appended hereto, together with analysis of the refuse tar and gas from the producer.

Analysis of Tar Made by Messrs. Totton and Hawthorne.

Sample of Tar No. 2.

The sample was grey when received, but very quickly turned black. On distillation it yielded:

	Per cent.
(1) Water	37.2
(2) Light oils (distilling below 230 deg. Cent.)	5.8
(3) Middle oils (distilling at 230 to 270 deg. Cent.)	8.3
(4) Heavy oils (distilling above 270 deg.)	23.2
(5) Coke	17.8
(6) Loss	7.7
	100.0

Much frothing occurred until the water was distilled off. Towards the end the temperature went higher than a mercury thermometer will record (360 deg. Cent.). The different fractions obtained were as follows:—

1. Water, faintly acid to litmus. Phenol could not be detected.

2. Light oils (below 230 deg. Cent.) became rapidly dark red in color. Specific gravity of crude liquid 0.930.

3. Middle oils (230 deg. to 270 deg. Cent.) became dark red. Specific gravity of crude liquid, 0.944.

4. Heavy oils (above 270 deg. Cent.), on standing, crystals of paraffin wax separated out to the extent of 5.42 per cent. of the fraction (= 1.26 per cent. of the original tar). The specific gravity of the liquid portion of this fraction was 0.906.

Analysis of Sample of Peat.

(Received on September 14th from Mr. Hamilton Robb, Portadown.)

Proximate Analysis.

	Per cent.
Water	18.98
Volatile matter	55.17
Fixed carbon	24.75
Ash	1.10
	100.00

Ultimate Analysis.

	Per cent.
Carbon	44.60
Hydrogen	5.42
Nitrogen	0.97
Ash	1.10
Moisture	18.98
Oxygen (by difference)	28.93
	100.00

Analysis of Average Sample of Gas During a Ten Hours' Trial.

Moisture in Fuel, 26 Per Cent.

	Per cent.
CO_2	10.6
CO	20.1
H_2	13.0
CH_4	3.7
Total Combustible	37.7
Calorific value (calculated from analysis)	144.0 B.Th.U.

THE BEAUHARNOIS ELECTRIC COMPANY.

A new electric company has obtained letters patent from the provincial government of Quebec. It will be called the Beauharnois Electric Company, Limited. The new company will have powers in the city of Montreal, and in the counties of Laval, Jacques Cartier, Hochelaga, Laprairie, Chateauguay, Beauharnois, Two Mountains, Argenteuil, Soulanges, Vaudreuil, Terrebonne, L'Assomption, Chambly, Huntingdon, Napierville, St. Jean and Iberville. They intend to construct large power houses and electric plants at different places.

The Beauharnois Electric Company, Limited, is an independent company and they declare they will never consent to join any trust or combine of companies. The first generating station will likely be constructed at Beauharnois and the power will be taken from the rapids in that locality.

THE LATERAL PRESSURE OF LIQUID CONCRETE.

The lateral pressure of liquid concrete is a most important question for the constructing engineer. In a paper before the Institution of Civil Engineers Mr. H. St. G. Robinson has presented some notes on a series of experiments to ascertain this pressure. The first experiments were conducted about five years ago, during the construction of a heavy retaining wall, by placing boards between the uprights of the vertical forms and noting the deflections caused by the various heads of concrete.

These experiments, however, were thought to be somewhat unreliable, owing to want of refinement, and Mr. Robinson has since carried out further experiments of a similar nature, but with an apparatus constructed to secure more accurate results. This consists of a strong cast-iron chamber, fitted with a sheet-rubber working face, and is arranged so as to be readily fixed in position on the forms. The chamber is filled with water or other suitable fluid, and the pressure exerted by the concrete against the working face is recorded on two sensitive low-pressure Bourdon gauges, conveniently situated behind the chamber.

In the apparatus first used the chamber was formed of timber lined with zinc; this, however, distorted on becoming wet and was abandoned in favor of cast iron. A glass tube water-column was also fitted for recording the pressures, but it was thought that the movement of the pressure face caused by the displacement of the water was not conducive of accuracy, as it caused the concrete to arch over, a movement that does not occur when Bourdon gauges are used.

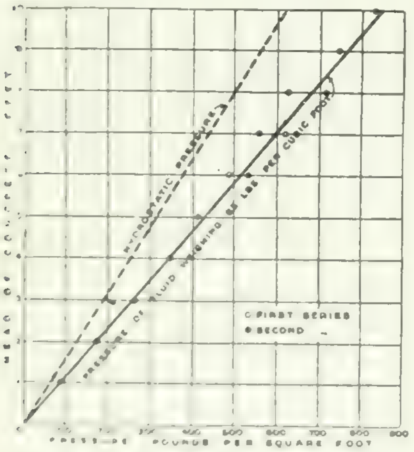

Diagram of Comparative Pressures.

A large number of experiments were made on different types of concrete structure. In heavy walls, large piers, and other members of fair size the lateral pressure exerted was found to be fairly uniform and practically constant for equal heads; but in reinforced-concrete columns of small dimensions, thin walls, and other light concrete work, the [illegible] forms and the concrete, together with the arching action, [illegible]

[illegible]

[illegible] sets of readings were taken, and each point on the curve represents the average value at that head.

The second series was carried out on large piers 4 feet square, the concrete in this case being a 1:2:4 mixture of cement, sand and Thames ballast, weighing 145 pounds per cubic foot. The conditions as to mixing and laying were similar to those of the first tests, and the concrete was carried up to a height of 10 feet above the centre of the pressure face. Each point of this second series represents the average of six readings.

In the first series the temperature was fairly uniform throughout, while in the second considerable variation was experienced; but the effect of the differences in temperature on the lateral pressure cannot be traced, and would appear to be very small.

The general conclusion to be drawn from these and other experiments is that the lateral pressure of concrete for average conditions is equivalent to that of a fluid weighing 85 pounds per cubic foot. For concrete in which little water is used in mixing the pressures are rather less, having an equivalent fluid value as low as 70 pounds per cubic foot in very dry mixtures.

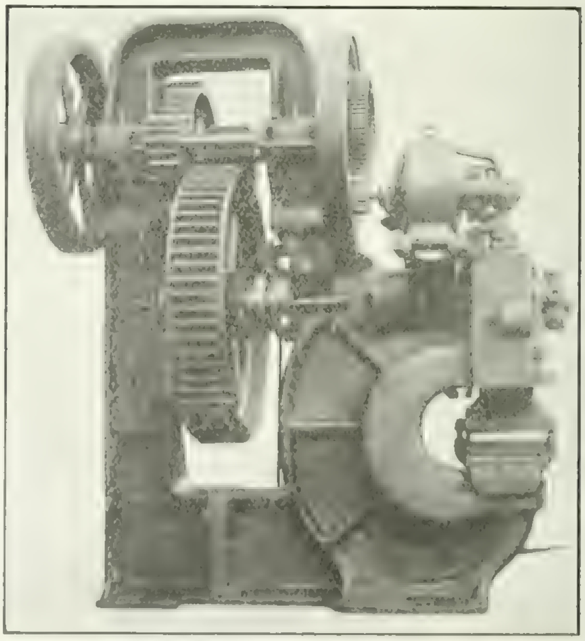
PUNCH AND SHEAR PRESS.

Economy of floor space, always an important item, is particularly so in a machine shop when it is desired to install any additional tools. The accompanying illustration will indicate how this may be effected in the case of a motor-driven punch and shear press, made by the Cleveland Punch and Shear Works, Cleveland, Ohio. The arrangement of overhead gearing renders it possible to make a very compact machine and one that is economical of floor space.

The machine complete with its motor weighs approximately 50,000 pounds. It is designed for very heavy work, having sufficient capacity to shear twelve inches of [illegible]-inch flat bars, and to punch a five-inch hole in [illegible]-inch plate. The various attachments, such as those for angle shearing, bar shearing, and punching are interchangeable.

The motor is of [illegible] horsepower capacity at 230 volts, and is of the well-known direct-current, commutating pole type, [illegible] adapted for this kind of work by the Westinghouse Electric and Manufacturing Company.



Motor-Driven Punch and Shear Press.

CANADIAN PUBLIC HEALTH ASSOCIATION CONVENTION.

The second annual congress of the Canadian Public Health Association will be held at Toronto next week on Monday, Tuesday and Wednesday.

This Dominion Public Health Association was formed about two years ago as a result of the meeting of Federal and Provincial public health officials invited to confer with the Commission of Conservation of Canada.

The formation of such a society has been well justified to date by the interest and enthusiasm shown in its work. Last year's meeting in Montreal was well attended, not only by medical health officers, but also by a great number of engineers who are interested in sanitary and public health matters. A special session of the congress last year was devoted to such subjects as water supply, sewerage, town planning, and the removal of garbage, etc. This section, therefore, dealt with the questions of public health, which are in the province of the engineering profession. One of the features of the general session was a symposium upon the question of biological sewage disposal, and the papers and discussion contributed thereon were among the most valuable features of the congress.

There is a great lack of combined and sympathetic action between the medical and engineering profession where these professions overlap, in matters appertaining to municipal and sanitary engineering. We have had occasion to note this regrettable feature before. It can only be by cordial co-operation and becoming acquainted with others' aims and ideals, that the best results will be secured.

We feel, therefore, that the Canadian Public Health Association Congress should be well supported by the engineering profession at this coming meeting. We sincerely hope that the engineers will be present in far greater numbers than last year, and will enter into the discussions with interest.

◆

THE CALLING OF TENDERS.

In Australia there has been a good deal of discussion lately concerning certain questions of interest to Canadians. The discovery that, though the prices of British firms were considerably lower, contracts for material had been given by the Victorian Railway Department (as also indeed, by the New South Wales Railway Department) to German houses (principally Krupp's) produced some plain speaking by the Premier of Victoria, who had ascertained that, though the English firms had been given the "go by" because their goods were "not sufficiently known" to an official concerned for the public safety, their specifications comply with the requirements of the British Board of Trade, and that they have for many years supplied most of the other Australian States with the particular line of goods in question. Judging by the Premier's specific directions, **it is not likely that the lowest tenders will ever again be rejected** in Victoria without most adequate reason, and it is not improbable that similar directions will issue from the Government offices in Sydney. Since then the tenders for rails for the Transcontinental Railway have all been rejected, because of the prices asked, but the Minister concerned hoped to induce one of the firms at least to take "a reasonable view of the expenditure that should be incurred by the Commonwealth for the rails."

In future it can be reasonably expected that British contractors will receive as generous treatment from the railway officials of Australia as German contractors. Analagous cases to the above sometimes arise in Canada. We believe, however, that British firms are receiving fairer treatment than they did some time ago. There is still great room for improvement, however.

* * *

PANAMA CANAL EXCAVATION

The estimates of excavation remaining to be done after July 1st, 1912, in order to complete the Panama Canal, according to the Canal Record, show an increase of 16,903,000 cubic yards over the estimate of July 1st, 1911.

In the Atlantic Division, the increase is 295,000 cubic yards, chiefly to provide for silting in the finished channel not covered by the estimate of July 1st, 1911.

In the Central Division, an increase of 4,615,000 cubic yards is made to provide for an extension of slides and changes in the Obispo Division.

The Pacific Division has an increase of 11,993,000 cubic yards, of which 3,199,000 cubic yards are to cover excavation in the Canal prism, in the locks and dams, and silting in the finished channel, which has become necessary since the estimate of July 1st, 1911. The remainder—8,794,000 cubic yards—is for the newly begun excavation for the drydock, coaling station, and terminal at Balboa.

* * *

THE CANADIAN HIGHWAY ASSOCIATION.

The first sign-post of the Transcontinental highway was planted on May 4th, 1912, in the town of Alberni, on the west coast of Vancouver Island. The Canadian Highway Association, which is responsible for the inauguration of the idea of a highway from coast to coast, was formed at New Westminster, B.C., about eight months ago, and one of the outward symbols of the progress they have made, is this marking of the route of the Canadian highway.

The conception of a transcontinental highway is a magnificent one, and one which we hope will be carried to a successful conclusion. In his address to the Association at the recent Alberni meeting, President Kerr said:

> "As with the building of a new railway, so with the starting of this Canadian Highway, we have decided that the first actual step should be marked with fitting ceremony, and in this we have received splendid assistance from the towns of Nanaimo, Alberni and Port Alberni, our hosts on this occasion.
>
> "From now on the route of the Canadian Highway is eastward, with Halifax as its destination. British Columbia has nobly done its share, thanks to the untiring energy of our Minister of Public Works, Mr. Taylor, and his able deputy, Mr. [illegible]. Over [illegible] is being spent on road improvements in this province this year, and could we but procure the active co-operation of all the other provinces in Canada the road would be completed, and completed within three years.
>
> "The Province of Saskatchewan has decided to spend [illegible] on roads this year, and a total appropriation of [illegible], has been made for the roads of that province. This is to be spent within the next two or three years. In Manitoba, only $200,000 has been allotted for road-building. This sum is, in my opinion, inadequate to the needs of that province, for my recollections of Manitoba are anything but pleasant, and I know of some roads where this total amount could be expended and yet leave that particular road in an unfinished condition. Ontario is waking up to the need of good roads; this is largely owing to the activities of Provincial Commissioner of Highways MacLean, who has $6,000,000 to spend on his work this year. In Quebec, we find that old province giving $10,000,000 for road work, and I think I am safe in saying that there is more interest in good roads in that province than in any other in Canada to-day."

If this transcontinental highway serve no other purpose than to arouse enthusiasm for the good roads cause, its inception would be justified. The thought of a first-class road running through province after province from coast to coast, is one which, if carried out, cannot do else than promote the good roads movement throughout Canada.

* * *

EDITORIAL COMMENT.

It is understood that the steel work on the Quebec bridge will be begun by November next. The Quebec Bridge Commission has just completed an inspection of the progress made to date on the substructure.

* * * *

The citizens of Galt recently had a repetition of the floods which caused so much damage last spring. The recent heavy rain storms were the cause. The Provincial Government will soon be forced to move in the matter of flood regulation by the force of public opinion.

* * * *

The Provincial Government of Quebec has recently appointed a Parks Commission composed of Sir William Van Horne, W. D. Lighthall, J. C. Walsh, Senator Boyer, Dr. Lachapelle, Mayor Lavallee and A. Michaud, for the city of Montreal. To any one who is at all acquainted with Montreal, it will be appreciated that the step has been taken none too soon. The growth of the city during the last few years has been phenomenal. The narrow streets and thoroughfares, however, have caused an increasing traffic congestion which, if allowed to exist much longer, will have the effect of throttling future progress. There is ample room for work on the part of the new commission in developing a unified plan for the future growth of the city and to the relieving of the present congested condition.

* * * *

In putting a price upon any sort of work one realizes that there is a price at which under the most favorable conditions one can do the work. There are contingencies which arise in the course of a job which are not included in the ideal programme. Some of these can be removed by foresight and good management, others seem to come under the class of "unavoidable." The bidder must not only decide the cost under average conditions, but must judge whether the conditions of the proposed job are average or special. He must balance the probabilities of unforeseen circumstances and decide how narrow a margin he dares to leave between the actual possible cost of the work and a living profit. The wisest bidders are not commonly those who disregard difficulties.

INVESTIGATION OF EFFECT OF FIRE IN A LARGE REINFORCED CONCRETE PAPER MILL.

At 11 p.m., May 25th, 1912, fire broke out at the pulpboard mill of the Androscoggin Pulp Company, South Windham, Maine. The Aberthaw Construction Co. built this structure in 1906, L. W. Jones, of Milton, New Hampshire, being the engineer. The building is of reinforced concrete excepting for a wooden roof carried on trusses of the same material. The window frames and sashes are also of wood.

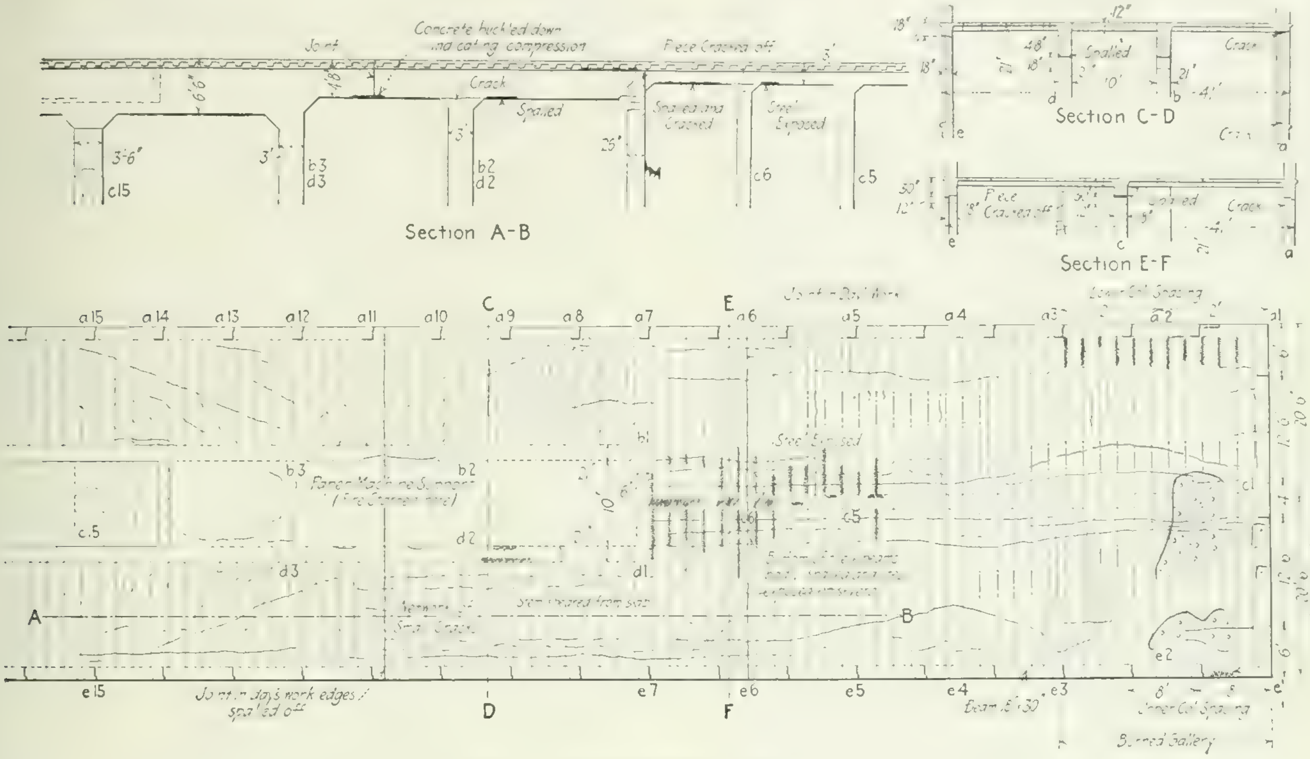

Fig. 1.—Androscoggin Pulp Co. Fire.

The blaze started below the machine room floor in the main building and set fire to the wooden panelling between the piers forming the outside wall of the lower story of the building. The burning panels set fire to the wooden sash of the window of the second story and from there set fire to the roof and to a wood and plaster gallery which was located along the side of the mill.

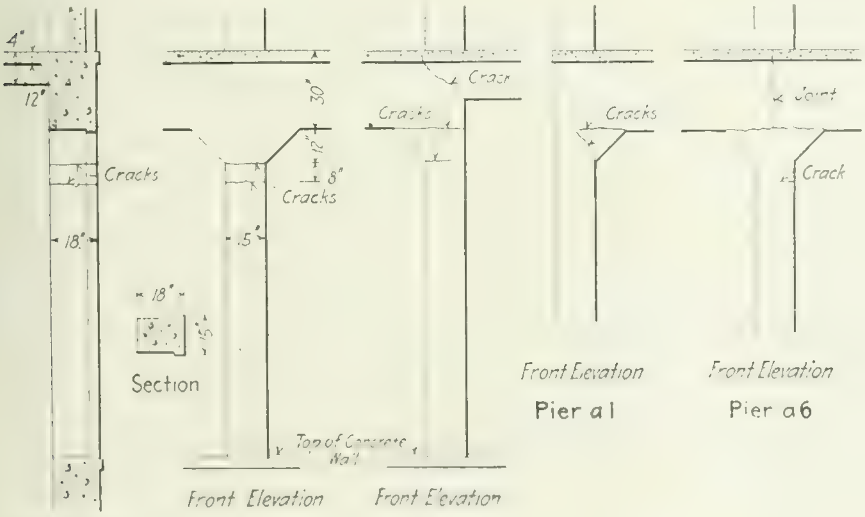

Fig. 2.

The fire was extremely hot, there being a large quantity of dry pulp-board piled inside the building and which burned at the same time. The intenseness of heat was so great that it bent and partly melted cast iron. Streams of water were thrown at the hot surfaces with considerable force and altogether the fire offered a particularly interesting test of the effect of fire on reinforced concrete work.

On May 28th, Morton C. Tuttle, secretary of the Aberthaw Construction Co., examined the building with Seth A. Moulton, of Portland, Maine, the engineer in charge of the rebuilding, and the latter made many shrewd suggestions as to the cause of some of the results observed. A few days later the engineer and superintendent of the Aberthaw Construction Company made a careful investigation and report, which is embodied herewith.

The fire started under the first floor in the middle of the building (Fig. 1). As far as could be observed, the principal effect of the heat was to expand the floor, causing a movement of the column. It was reported that on the morning of the 26th the end wall of the mill was observably out of plumb. At that time the concrete was generally so hot that one could not stand putting his hand on it outside of the building. Later on, this particular wall drew back again to the perpendicular. The crack at the pier, crack "A-7" (Fig. 2) shows the effect of this movement on the outside wall, where the size of the wall beam changes due to different spacing of the columns. The cracks above and below the bracket of the column also seemed to indicate the longitudinal movement of the floor.

The cracking of the columns at the side of the building seemed to indicate the same sort of expansion. These cracks occurred at both top and bottom of some of the columns. The top cracks are shown in Fig. 2.

It will be noticed (Fig. 1) that in the section of the floor at the wall end of the building (right end) the main cracks run longitudinally and are clearly marked, and that the cracks at right angles to the building are comparatively few.

Where the floor span decreases next to the large girders which support the paper machine the cracks begin to run at right angles, and end with diagonal cracks which die away into the part of the floor which was not heated. It is suggested that the cracks at the wall end of the building which are parallel to the main girder occurred because of the unequal heating of the big mass of this girder and the thinner floor slab. causing unequal expansion of the two masses. A similar cause may have produced the crack along the wall beam.

Because there was a considerable amount of water thrown upon light colored pulp and because the under side of the ceiling was blackened by the smoke from the fire, when the water carried the pulp through these cracks in the floor it showed these cracks very clearly on the under side. The cracking of the floor at the end of the paper-machine foundation is shown on cross-section "CD" (Fig. 1.)

At the end of the machine room, in the gallery, there was a stock house built with concrete piers, supporting a wooden floor carried on steel beams, with wooden columns carrying a wooden roof. The walls of the building were "hy-rib" metal. At the base of the building there were some brick walls. The interesting feature of the particular building was that the foundation piers which were subjected to high heat were built of concrete, rich in mortar. This concrete withstood the action of the heat much better than did the granite concrete of the main mill.

The stone used in the concrete on this job was coarse grain crushed granite. The sand was of good quality and the work was carefully done. The placing of the steel was better done than on the average job.

NON-PULSATING PUMPS.

A most interesting exhibit at the Canadian National Exhibition was that shown by the Luitwieler Pumping Engine Company, of Rochester, N.Y.; Canadian agents, The General Machinery Co., Limited, 526 Traders Bank Building, Toronto. One of the pumps exhibited by them is a triplex non-pulsating pump with 4 x 6-inch cylinders and six-inch stroke. The pump is operated by a five-horsepower motor, and pumps about 150 gallons per minute. It is designed to operate from 150 to 200 pounds pressure. One [illegible] vibration in the running of the pump. The power is applied continually and evenly at all times by a nicely balanced arrangement of [illegible].

The [illegible] of the Luitwieler pumping engines [illegible].

[illegible]

The power transformed by the cams is applied to the pistons in cylinders at any depth below the pump-head through two balanced sets of rods, hung one from each of the sliding yokes. By means of this arrangement it is always possible to keep the pumping engine at the surface no matter what the depth of the well or shaft may be. As the moving reciprocating parts throughout the entire equipment are in equilibrium at every part of the stroke, operation is effected upon much less power than ordinarily is required.

The pump shown at the Exhibition was an electric pumping engine operating at full speed while supported upon eight water glasses standing in pairs bottom to bottom upon an ordinary square saw-horse. It was not braced or supported in any manner. The pump was operating at 50 revolutions or 100 pump strokes per minute, and with so little vibration that a coin placed on edge on the pump frame remained without falling.

The non-pulsating triplex pumps are used for suction and pressure service, and are particularly adapted to water supply and fire protection of tall buildings and to municipal and corporate waterworks. The company use the duplex cam type upon all well work, with submerged pumping cylinder whenever possible, or the double chamber pump when suction is preferable.

All pumps made by the company are adaptable for direct connection with any kind of driving power. Valves of various types are used according to the nature of the substance to be pumped. The pumps are made to handle any liquid or semi-fluid matter.

CONSOLIDATION OF STREET CAR FRANCHISES.

During the past few weeks there has been quite a change in public opinion in respect to the British Columbia Electric Railway Company. For many weeks past, a Greater Vancouver committee has been at work trying to effect a consolidation of the street car franchises of the various surrounding municipalities. This city has the option of buying the system in the city proper in 1918, this will not give control of the franchises in outside places, where they extend for varying terms of years. Some of the aldermen think that because they have the option of buying that they have the street railway market cornered, and are standing firm. On the other hand, ratepayers are now taking up the matter, and at a meeting in Fairview voted against this attitude and suggested that the people be given a chance to express an opinion in the matter. Even those who stand for muicipal ownership, confess that civic ownership of public utilities might obtain in instances. create irritation and that these franchise entanglements would be quite an incubus. It is realized that while the principle of civic ownership o public utilities might obtain in instances, this principle is subject to qualifications and the laws of general expediency. At first it was thought a twenty-five year term was too long for a general consolidation, but it is recognized by many that such a period is not out of the way if extensive enlargements are to be constantly carried on, for money cannot be had at a satisfactory price with a shorter term. Business men recently returned from the Old Country report that investors there are looking for a better rate of interest than formerly. That being the case, a short-term franchise would be of little use to the British Columbia Electric, which will need much money. With the feeling now obtaining, it is not improbable that the company and the city will be able to get together and agree to some mutual proposition, especially in view of the fact that at Point Grey there is a strong desire to have the street cars running once more.

CANADIAN NATIONAL EXHIBITION.

There has not been a season in which so much competition has been shown among mechanical manufacturing firms as this present one. A walk through the Machinery Hall showed many European firms that were competing against local firms and those from the United States, that heretofore have had the displaying space to themselves.

The Consolidated Optical Company, Limited, of Toronto, again secured their advantageous station near the main entrance of the Manufacturers' Building, and displayed a line of surveyors' instruments and meteorological devices that are made in Canada. In connection with the latter they showed a wind-gauge and automatic recorder, made-to-order for Government officials.

Messrs. William Hamilton Company, Limited, of Peterboro', Ont., had a prominent position in the Machinery Hall, and took full advantage of the same to demonstrate the qualities of the Samson Water Wheel. One large turbine was erected in their booth, and ample facilities were given to examine the mechanism.

The Canadian Boving Company, of Toronto, had an interesting exhibit in the north-east portion of the Machinery Hall. This was made up of a twelve horse-power "Bolinder" semi-Diesel crude oil engine driving a dynamo and water pump, the easy working of the latter being shown by a stream of water flowing into a large galvanized iron tank. A large sign overhanging their exhibit stated that this firm make a specialty of power apparatus, and numerous devices demonstrated below amply bore out the statement.

Messrs. John Millen & Son, Limited, occupied the south-west corner of the Machinery Hall, and had on display an interesting exhibit of chains, and a cabinet which was fitted up for the special purpose of demonstrating the mechanism of the "Coventry Noiseless Chain," for which they are the agents. They also had a number of link chain and several blocks and tackles, together with other labor-saving devices dependent upon chains for their operation.

The Canada Metal Company had their usual artistic and useful exhibit of various alloys and ingot metals, and were showing samples of lead wool and demonstrating its qualities as a calker for pipes. This wool resembles in appearances the steel wool often used by cabinet makers to remove varnishes and polish from woodwork. It is in very thin threads and well tangled together; resulting in a mass that is soft and spongy to the hand.

Messrs. Baines and Peckover, of Toronto, secured the southeast corner of the Machinery Hall and showed products coming under the title that they have selected for their exhibit, viz., "The Iron Store." Bar iron and steel, both plain and ornamental were shown in various lengths, and one wall was devoted to the display of "Atlas" metals, alloys and babbitt. The front of their booth is taken up with two or three rolls of "Lincona" belting, for which they are the agents. This belting is a composition with a canvas finish on one or both sides, resulting in a surface that has a powerful grip on the pulleys.

The General Machinery Company, local offices Traders Bank Building, Toronto, were demonstrating the merits of the Luitwieler pump in their exhibit, and for this purpose have erected a tripple stroke pump and a means of showing the force and evenness of the stream. A hydro-pneumatic water supply system is shown in the rear. This is intended to give a high-class water service to country residences and other buildings difficult of access to the mains of a municipal pumping plant. The pump was driven by an electric motor, and the latter controlled by the water level in the tank. A device was also shown whereby a gasoline engine may be started at a signal, which is automatically given, when the water in the tank falls below a pre-ascertained level. The electric device is entirely automatic but the gasoline option is a good substitute in localities where a reliable electric pressure cannot be obtained.

Messrs. Wettlaufer Brothers erected a large tent to the southwest of the Machinery Hall and gave semi-open air demonstrations of the merits of their heart-shaped concrete mixers as well as their various concrete block and brick machines, and other concrete specialties.

The building formerly occupied by educational exhibits and hand work was given up entirely to the Canadian Gas Association. In this building several interesting exhibits might be seen, among which was that of H. Mueller Mfg. Co., Canadian factory, Sarnia, Ont. (about November 1st). This firm specializes in the manufacture of gas main equipment, gas cocks, service boxes, waste cocks, etc. Their exhibit was much enjoyed by municipal officials, while the other attractions in the building, being to a large extent of a domestic nature, were visited by householders.

The Canada Cement Co., Limited, had a booth under the grandstand at which complete information could be obtained in regard to concrete roads and all other forms of concrete construction. This exhibit was one of the most unique in the grounds. It consisted of a set of illuminated transparencies of everything from a concrete fence post to a concrete viaduct. Another feature of this exhibit was the illuminated posts around the booth, being the first used on the grounds.

A feature of the fair this year was the new Government Building, erected during the past season to the west of the grounds. All the provincial governments were allotted space to demonstrate the representative merits of the districts coming under their jurisdiction. Excepting the province of Ontario, all the exhibits were of a mercantile nature and the spaces were used to exhibit wheat, minerals and natural advantages. The province of Ontario have a separate building, which is devoted exclusively to exhibits of this nature, so that their space in the Dominion Government building was used as a health exhibit and every effort was put forth to educate the visitors regarding the means of combating disease and the importance of this department of the provincial governing body.

A fair-sized pressure filter, manufactured by Messrs. Bell Bros., of Manchester, England (local representatives Bell Filtration Company, of Canada, Limited, 305 Kent Building, Toronto) was installed and a Luitwriter triplex pump connected in such a way as to illustrate a water purification system suitable for a town of one thousand persons with an estimated consumption of one hundred gallons per day each.

A bacteriologist was in attendance at the display of disease producing cultures which formed a splendid show. Many antitoxins were also shown, which graphically showed the progress made by science in combating diseases known to be due to the presence of micro-organisms in the body.

TRANSPORTATION OF MATERIAL IN MODERN LARGE INDUSTRIAL PLANTS.

By H. W. Arnold, Supervisor of Power and Maintenance, The Jeffrey Manufacturing Co.

During the last few years much has been written and spoken relative to efficiency in so far as the manufacturing end of the matter is concerned, but in very few instances has the transportation of material in and about manufacturing plants received the attention its importance deserves.

View of Part of Industrial Track System.

Necessarily, the transportation facilities of a plant include all the surface and overhead devices used in moving material from one point to another, but in this brief article it is propos·d to consider only the surface [illegible]

In most instances large manufacturing plants present a rather difficult transportation problem. This is due to the unsymmetrical growth of plants of large proportions owing to the fact that in a great majority of cases the expansion was not anticipated or provided for in the original conception.

The Jeffrey Manufacturing Company, of Columbus, Ohio, is spread out over an area [illegible] of floor space. This plant manufactures a [illegible]

[illegible] sideration.

[illegible] truck working on a 36-inch gauge industrial track. A careful study of existing conditions made plain the fact that a very material saving could be effected by establishing a more efficient transportation system.

After considering the problem from every angle, it was decided that the Jeffrey storage battery trucks and industrial cars offered the best and most efficient means of surface transportation. Accordingly, the industrial railway was extended to take in all departments and a systematic method of car dispatching established. The accompanying plan gives an idea of how thoroughly the different buildings are served by the industrial track.

As soon as this system was established, very rigid instructions were issued that absolutely no material was to be transported by other means than the storage battery trucks and industrial cars. It was immediately found possible to dispense with the services of a two-horse team, 28 two-wheeled warehouse trucks, 13 four-wheeled trucks, 8 wheelbarrows and 18 men whose whole time had been devoted to this purpose. This effected an annual saving of more than $600 per month over the cost of the former system, taking into consideration the interest and depreciation on the investment, operating, maintenance, costs, etc. The monthly tonnage handled is close to 4,000 tons. Viewed from its present efficiency, it would seem almost an utter impossibility to go back to the previous or any other method of transporting material.

The Jeffrey storage battery truck is so simple in design and rugged in construction that it does not require the service of skilled operators, and the maintenance and operating costs are extremely low.

Operation of Industrial Track System.

The industrial railway track shown in the illustrations gives a comprehensive idea of the system, and the wide range of usefulness for transporting material with the trucks. These trucks will pay for themselves in a very short period of time and especially where an industrial track system is already installed.

THE MUNICIPAL ZONE SYSTEM.*

By B. Antrim Haldeman.

Some of the nations of Europe, out of a wealth of unfortunate experiences in the rapid growth of industrial cities and the crowding together of the people in them, have evolved what is known as the "Zone System" for controlling the use and occupation of land.

The system had its origin in the deplorable living conditions which were forced upon the working people and poorer classes of Germany during the period of industrial progress that has absorbed the energy of the German people since the Franco-Prussian war, and during which old feudal towns have been transformed into metropolitan cities and the country side into a forest of factory stacks. The administrative machinery of the towns, confronted with new and perplexing problems due to the rapid increase of population, were for many years unable to cope successfully with the new conditions by reason of the manner in which land was held, its sudden rise in value, and the lack of any authority to interfere in any effective manner with the owner's disposition and use of it.

The swift progress of industrialism throughout the German States encouraged the rapid growth of industrial towns at a time when the social conditions and the manner of living of the common people were not conducive to either the morals or health of crowded communities; the workshop and factory drew upon the farm and rural hamlet for their labor. and the working people, unable to obtain proper dwelling places, herded in caves, cellars, and unsanitary buildings. like rabbits in a warren. The rapid increase or urban population offered a fertile field for exploitation by the great landowners who erected barrack-dwellings of many stories and rooms which were an improvement over tne caves and cellars and into which the working people crowded. Although these dwellings marked much improvement in living conditions they still bred many evils from the too intensive occupation and to correct these and provide greater assurance of the public health and safety a multiplicity of building regulations were enacted by the municipal authorities.

Ministerial decrees were issued tending to enlarge the authority of local councils in matters relating to the erection and occupancy of dwellings; gradually the fact dawned upon the law makers that the power and prestige of the empire among the nations of the earth depended as vitally upon the health and efficiency of its working people as upon the courage and loyalty of its fighting men. By slow degrees, slow because opposed by the great landowners who dominated many of the legislative bodies, the ministerial decrees were enacted into laws granting broad autonomy to municipalities and enabling them to strike at the root of the evil of their housing system by checking the increase of the speculative value of land, such speculative increase in some cities having risen 400% in a single year. Municipalities were also authorized to purchase ground, to erect dwellings, and to loan public funds to societies for the erection of workmen's homes; much encouragement has been given to the erection of one-family houses, and home owning has been made possible among the working people.

The story of the industrial and social evolution of Germany is an intensely absorbing one, but we consider here, and that but briefly, only the manner in which the municipal authorities exercise the powers vested in them to regulate the development of private property. This is accomplished mainly through the employment of the "zone system," under which the municipal department having charge of city planning, in establishing and extending the street system, also establishes the building lines, determines what percentage of the property may be built over and the arrangement of the buildings themselves, whether they shall be erected in solid rows, in pairs, or singly; also the distance between the buildings when built singly or in pairs, and the number of floors or stories. No appeal from the established regulations can be taken after the plans have been completed, examined, and finally approved by the several independent committees having jurisdiction. The plans frequently show three fixed lines in a block; the line to which the street is to be opened and improved, a line of restriction, a certain distance from the street line beyond which no building is allowed to extend, and an interior line fixing the boundary of the court yard or garden within which no structure is permitted.

The term "zone" as applied to the system is somewhat of a misnomer and misleading; although the general theory under which it is applied is, that the buildings should be lower and farther apart the greater their distance is from the centre of the city, the arrangement is not one of concentric girdles, as might be supposed, but a division into districts. irregular as to area and boundary and regulated in accordance with some local characteristic or special adaptability for certain classes of buildings; in fact, it sometimes occurs that a "zone" consists of a single city block, or even part of a block. True zones girdling the city would result in alternating rings of high and low buildings or a single indeterminate outer zone, regardless of topography or local conditions, and are considered unwise, if not impractical; so also are very large zones, or districts, since the application of absolute restrictions would prevent the establishment of local business and trade centres for the convenience of the people.

The system has undergone considerable modification since its introduction; keen judgment and great care are essential in determining boundaries and in imposing regulatons which will permit property to be used for the purpose for which it is best adapted; although there was, and still is, considerable opposition to it in some instances, it is gradually producng the desired results, checking land speculation and inflation of values, discouraging the erection of barrack-dwellings, encouraging the erection of one-family houses, and making it possible for people of modest means to own their own houses.

Just as the industrialism and commercialism of Europe has created congestion and bad housing conditions, so are the same evils following in the wake of the tremendous activity along industrial lines in this country; the centralization of trade and the lack of adequate transportation facilities are, perhaps, the most powerful factors in producing a too intensive occupation and use of land; the desire to make property produce the largest possible income is a characteristic of landlords the world over, and tenement houses under lax regulations are splendid revenue producers.

Although the zone system as employed in Europe is the outgrowth of a long and persistently fought battle for the improvement of housing conditions, it has resulted in other economical and administrative reforms and it is along these lines that its application in the United States might also produce important results and be of great benefit. It would enable the municipal authorities to predetermine the character of improvement in any given area and, as the permanence of the improvement would be assured, very large economies in planning of streets, the construction of public works, and the conducting of general public service could be affected.

Under the zone system the permanent population of any given area may be determined with a reasonable degree of accuracy before a single building is erected upon it; with this factor known it is possible to intelligently forecast the needs of the district for every class of public works and public service and to plan accordingly, with the confidence that whatever is done will be done properly, permanently and economically.

---

*Abstract of a paper read before the City Planning Conference, Boston, Mass., May, 1912.

Transportation is the great, controlling factor in the growth and development of the modern city, and the most difficult problem municipalities are called upon to solve; its difficulties would be greatly lessened if the density of population could be kept within reasonably certain limits; this is understood in the German system of town-planning and the locations of the trams, or street-railway lines, are determined as the street system is extended and are based upon the volume of traffic likely to be created by the known population and the predetermined character of the territory they will serve; the same is true of main, or trunk, lines of every kind of underground service: sewers, water pipe, electrical lines, pneumatic tubes; and subways, pipes, and tubes for every purpose of subterranean transportation. The number and capacity of public service structures under, upon, or above the surface depends upon the density of the population and the local needs of the community; these elements being known the original construction of public works can be of the most permanent character and the liability for repairs, reconstruction, and enlargement can be reduced to a minimum.

Wide streets, planned with the almost certain knowledge the zone system would give of the traffic requirements for long years of service, would permit of a far more economical system of secondary and residential streets than we now find in most of our cities. In almost every city we find large areas laid out with streets of uniform width and uniform improvement, but they seldom carry an equal amount of traffic or are of equal public use except in congested localities; certain ones, by reason of easier grades, better connections with important points, greater business activity, or other favorable local conditions, attract the greater volume of traffic, leaving perhaps half a dozen adjacent ones unused and unlovely expanses of costly pavement.

[illegible] permit property to be restricted to the use for which it is best adapted by natural conditions. If hilly and picturesque districts were reserved for high-class residences, or for residences requiring lawns or gardens, the cost of improvement, both as to property and streets, would be greatly reduced by removing the necessity for the [illegible] small [illegible].

It [illegible] neighborhood enabling the builder to realize large profits; [illegible]

[illegible]

the difficult problem of transportation and with its brother evils, the subway and the tenement house, for both of which it is partly responsible, it is moving steadily toward the creation of an abnormal condition of urban life. This menace of the skyscraper, the subway, and the tenement can only be removed by the enactment of regulations limiting the height of buildings, defining the areas within which those of maximum height may be erected, and prescribing the percentage of surface area they may cover and the amount of light and air space around them.

In no department of city building is there a larger opportunity for the advantageous application of the zone system than in the defining of the areas within which industrial establishments may be erected. Mills, factories, and workshops of almost any kind may now be set down in any locality which seems favorable to the promoter of the enterprise. Such establishments must invariably have facilities for transportation by rail or water, or both, especially if they are conducted upon a large scale, as most modern establishments are. Their random placing may work to the disadvantage of an entire neighborhood. There is a large economy for any concern in having transportation companies deliver and receive freights directly at its doors and the problem of supplying such service is a difficult and complicated one where industrial plants are distributed widely throughout a community.

The confinement of industrial establishments within certain prescribed areas would protect residential districts from invasion by incongruous or otherwise objectionable institutions and would immeasurably simplify the problem of industrial transportation, both local and foreign. The creation of factory zones in locations conveniently reached by rail or water would permit the development of terminals of maximum efficiency at a minimum cost; drayage between the mill and the shipping station is a large item of expense to the manufacturer, and the collection, classification, and distribution of freights from or for scattered and isolated yards are distracting problems for the traffic manager and the yard master; the short haul, the reduction or concentration of trackage, and the saving of time and energy where freights originate, or are distributed, within certain prescribed areas, all count for economy in trade and transportation. Main traffic streets for through travel could be kept clear from obstruction by railroad crossings and sidings, and to a considerable extent from costly bridges, if freight yards and freight carrying lines were kept within industrial zones.

So apparent do the advantages of the industrial zone seem, and so complex and costly are the problems of industrial transportation under present methods, that it is strange the manufacturers and transportation companies, in their efforts toward scientific and economic management, have not used their influence to establish such a system; indeed, some of the large industrial concerns have found such an arrangement so desirable that they have established their own industrial colonies in which their factories and freight service are entirely separated from the residential sections; only the most extensive ones, however, have been able to do this successfully, the smaller ones having found the problem of obtaining and keeping skilled labor a difficult one at a considerable distance from large towns.

Any attempt to engraft the zone system into American schemes of municipal development would probably meet with great opposition from landowners, real estate speculators and speculative builders, and from large interests not directly concerned in the development of land. The objections of the first would doubtless be based upon the abridgement of their right to do as they pleased with their own property, of the second upon the cutting off of prospective profits, and of the third upon the general proposition of the invasion of vested rights. All of these arguments were advanced against the system in Germany and all had to give way at the behest of the people.

The plea for the protection of the vested right has not the force it had a few years ago. The great unrest we find throughout the country to-day may readily be traced to the exploitation of nearly every line of activity under the so-called vested rights; the days of the perpetual franchises and special privileges are passing away, and, while every reasonable safeguard must be maintained around the rights of property and invested capital, their leveling down to the service of people who have given property its value and capital its reward is proceeding steadily.

A long process of reasoning might be necessary to convince people that our municipal officers may be trusted with such large powers as are involved in the practical application of the zoning system, for there is a too well-founded suspicion that public service does not always mean serving the public. But the administrative machinery of our cities is passing from the control of political and corporate interests to the control of enlightened public sentiment; the people have been thinking and inquiring into public affairs, and they are learning that the city, with all its vast resources and wealth, is theirs, created by their energy and labor; they are learning what a tremendous organism the modern city is, and, in the pride of their own work, are beginning to assert their right to rule it. Municipal government in the United States is undergoing an evolution that points toward material improvement and the time may not be far distant when our cities will be governed as wisely and honestly as those of Germany, where the power of the local officials is so great, and so unrestrained by constitutional or statute laws, that only capable and trustworthy men dare be placed in the public service, and where election to a public office is a real honor.

PUBLIC UTILITIES AND REGULATION

From its very nature the operation of a public utility, both from the standpoint of the public and of the utility corporation, must be a monopoly. Operation by two or more companies means additional poles, wires, tracks, or pipe mains in the streets and while competition may for a brief time mean lower rates, such lower rates mean a poorer service until finally one, or all, of the corporations are forced to the wall, or the weaker company is merged in the stronger with inconvenience to the community and loss to the investor.

These opinions were expressed by ex-Mayor MacIlreith, of Halifax, at the recent convention of municipalities.

"But to most people," he continued, "the words corporation and monopoly signify the necessity of girding on armor for immediate warfare in order to obtain even a semblance of public rights. Therefore, at the outset, it behooves the public utility corporation to show to the community within whose bounds it operates, by actions, not promises, that a good service at reasonable cost is furnished and that sufficient capital is provided from time to time, to expand or extend the service as the fair claims of the community for such expansion or extension arise. By acting thus, the natural prejudices of the public against the corporation ought to be very largely removed and fair treatment should be accorded the corporation by the community evidenced by a willingness to pay a fair and reasonable price for the service accorded.

"If these ideal relations could be established, there would be no need for regulations, but perhaps, while not possible of absolute establishment, they can be approached unto, and the necessity of recourse to the regulating body rendered unnecessary in most cases.

"The right of the state to set up bodies to regulate public utility companies is undoubted, and the duties and powers of such bodies are, of course, contained in the acts of the legislature creating such utility boards. After such a board has been created, the fear of the public of the monopoly largely vanishes. Under all utility commission acts, it is the duty of the board to see that the corporation renders good service at a fair cost, allowing the legitimate investor a fair return for the money he has invested.

"In our province the Act creating the public utilities board is chapter 1, of the Acts of 1909. At the last session of the legislature an Act (chapter 64), amending the above Act, was passed to come into force when proclaimed by the Governor-in-Council. As these Acts are available to all it becomes practically unnecessary for me to do more than mention a few main points.

"In the first place every public utility is required to furnish reasonably adequate service and facilities, and the charge made for such service shall be reasonable and just, and every unjust or unreasonable charge for such service is prohibited and declared unlawful.

"Secondly all rates must be filled with the board and there must be no discrimination. And thirdly, the board is empowered to value the property of public utilities and regulate the issue of stock.

"The method and procedure for the hearing of complaints is made as simple as possible. In order that personal or imaginary grievances may not be made the pretext for hearings the Act provides that the complaint must be made by a municipal corporation or by any five persons, firms or corporations. Our Act, like other utility Acts, is designed to safeguard the rights of the public and at the same time to only require the utility corporation to do what is fair and reasonable and in filing rates and charges to have in view a fair return to the investor.

"While as a rule the public sees only its own side it must be remembered that there are two sides to every question, and it is for the regulating body to weigh these carefully and dispassionately, and while having in view the reasonable demands of the community, they must treat the corporation with fairness."

LOCATING UNDERGROUND PIPES.

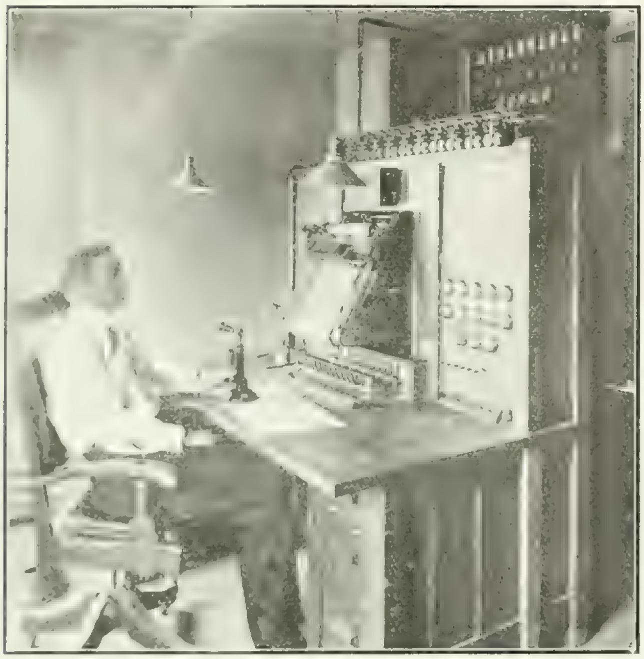
In waterworks systems there are often pipes, the exact position of which is not recorded, and when repairs or new connections are to be made with such pipes, a great deal of time and money may be saved by the use of a device which will indicate their positions, says Engineering News for August 15, 1912. Some electric devices have proved successful in this field, one of them being based on the principle of causing a slight flow of electric current in the pipe, which thus becomes a conductor. When an electric coil is brought within the field of this conductor, a current will be induced in the coil and cause a sound in a telephone receiver connected to the coil. The sound increases or decreases as the coil is carried nearer to, or farther from the underground conductor, but ceases when nearest to it; that is, directly over it. By locating a number of points directly over the pipe, its situation is accurately determined.

In using the instrument, wires from a portable battery are attached to suitable connections and the operator, carrying the instrument in his hand and the receiver at his ear, walks across the supposed line of the pipe, the exact position being indicated by the absence of sound. To locate a service pipe the battery wires would be connected to the house cock and hydrant, creating a current along the service line. This device is manufactured by the Modern Iron Works, of Quincy, Ill., and is used by a number of water companies.

THE SIMMEN SYSTEM OF RAILWAY SIGNALLING AND DISPATCHING.

By Mr. Paul J. Simmen.

The executives of both steam and interurban electric railroads in Canada and the United States are earnestly seeking greater safety, greater facility in operation, greater track capacity and better discipline for handling their traffic at a cost bearing some reasonable relation to their earning capacity.



Dispatcher Reading Movements of Cars from Sheets.

The present systems of train control divide themselves broadly into two divisions, namely, dispatching and signalling.

The dispatching section requires elaborate rules, timetable rights and dispatchers. These dispatchers must, through some form of telegraph or telephone system, including operators at numerous stations along the line, convey orders to the conductor and engineer; reports of the actual train movements being wired to the dispatchers by the operators or train crews.

The efforts of the signalling section have been to prevent collisions between trains endeavoring to follow the running orders based on the time table rights, train rules and dispatchers' order. This second section involves all sorts of devices from target boards to elaborate automatic [illegible] ing devices, and, in some instances, automatic stops.

Practically no improvements have been brought about in the dispatching section for a generation, and the various [illegible] of railroad [illegible], [illegible] and State Boards, have repeatedly condemned these methods as being totally inadequate to meet the requirements of present day traffic. The large number of accidents annually recorded on roads throughout the country forms conclusive evidence of this fact.

In the signal division fine results have been obtained, but these results have been accompanied not only with a large first cost, but more important still, with a large yearly maintenance expense. Automatic or manually controlled block signals are essentially only auxiliary to the dispatching section, and where used, the combined operating expense of both the dispatching and signal section is materially larger.

The Simmen system is especially designed to meet a long-felt want. It is absolutely safe; it reduces delays in train movements; it increases the track capacity and it affords a simple and ready means of increasing the efficiency of train crews, at a cost much below that of any other known system.

The Simmen system is radically different, both in intention and mechanism, from anything else now offered to railways. It breaks new ground by combining into one all the essentials of the dispatching and signalling sections. It is not an effort at detail improvement, but an entirely new and effective system for the management of railway traffic, which is safe, accurate and inexpensive. The claims made for the system and its many desirable features have been fully justified by the results obtained from actual installations and tests of the system under service conditions.

The actions of the persons upon whom the safety of the traffic depends, namely, the dispatchers, train crews and telegraph operators, are all protected against error. The responsibility first of all rests upon the individual himself, but any error which he would unwittingly make is throughout the system prevented or corrected by electrical or mechanical means. The dispatcher is protected against error by an interlocked switchboard. The engineer or motorman is given a more effective signal than heretofore, appealing both to the sense of vision and hearing, but should he fail to obey the signal to stop, the air brakes are automatically applied. The telegraph operator, whom statistics prove to be the weakest link in the present chain of train operation, is dispensed with altogether by the Simmen system, thus removing a frequent cause of error, and making a large saving in operating expense possible.

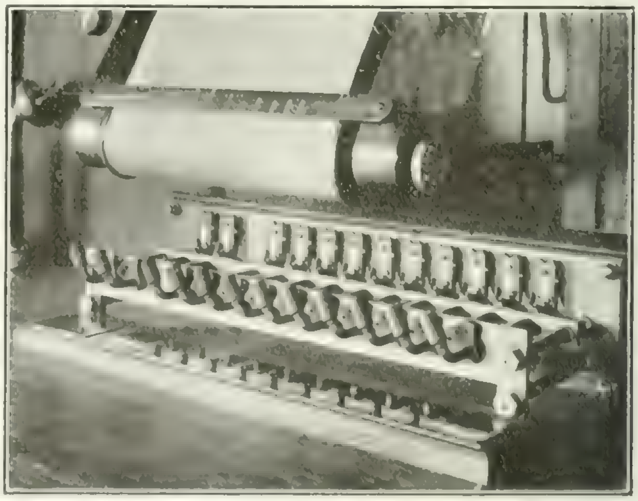


Fig. 1. Dispatcher's Switchboard. (Switches all Set for Westbound Movement.)

The system is not an experiment. It has been in use for nearly three years on the Toronto and York Radial Railway with marked success. A test installation of 18 miles was made on the Indianapolis & Cincinnati Traction

---

[In the issue of *The Canadian Engineer* of June 11, [illegible], there appeared a description of the Simmen Automatic Railway Signal System which had, at that time, just been installed on the [illegible] division of the Toronto and York Radial Railway. The following article presents a more complete description of the system, prepared by the inventor.—Ed.]

Company's line, in the State of Indiana, and has been in use successfully for three months, operating successfully at speeds of 85 miles an hour. As a result of this test the Railroad Commission of Indiana has approved the system and has ordered its use on the entire Shelbyville division of this company, a distance of 45 miles. The Indianapolis & Cincinnati Traction Company were so well pleased with the test that they placed their order for the equipping of their entire mileage of 100 miles with Northey-Plummer, Limited, of Toronto and Indianapolis, Indiana, who control the patents of the Simmen System. The system is approved for test by the Block Signal and Train Control Board, and is endorsed by many signal engineers of the country. Electrically speaking, it is throughout, in accordance with the requirements of the Electric Railway Association.

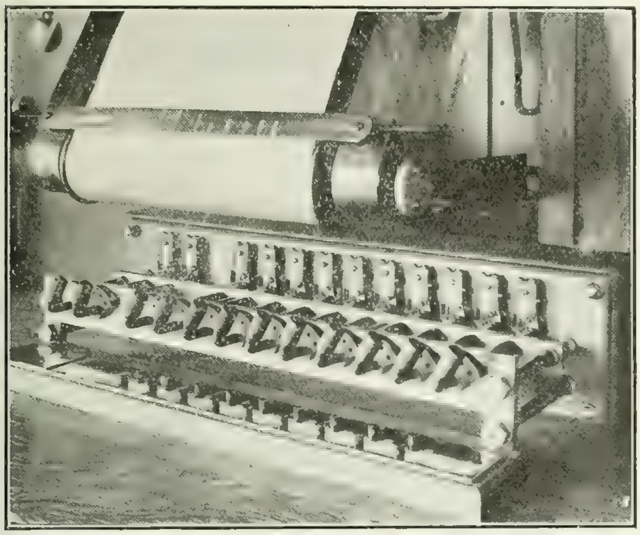

Fig. 2.—Dispatcher's Switchboard. (Switches all Set for Eastbound Movement.)

An attractive feature of it is its elasticity and its fundamental simplicity. It provides for an automatic record of train movements in the dispatcher's office in graphic form, interlocked switches by which dispatcher can signal danger or clear indications to engineer or motorman direct in his cab, and direct telephone communication, between engineer and dispatcher. Additional protection which may be desirable and justifiable for heavy or high-speed traffic, such as automatic block, track circuits and automatic stop, can be added from time to time and made to fit in and work as auxiliary to this system without prohibitive complication.

The following are some of the advantages of the system:

Safety.—The dispatcher and engineer are protected against error by automatic devices. The entire system is so designed that any failure whatever in the equipment will result in danger indications. The telegraph operator being eliminated, his errors disappear also. Every movement into a new block must receive a positive clear signal, which an engineer must await, irrespective of the running orders or time table rights.

Facility.—The system facilitates quicker train movements to an extent equal to placing (eight-hour shift) telegraph operators at every passing siding on a single track road, or block station on a double track road. The time requisite to deliver instructions to the train crew through a third party (the telegraph operator) is saved, as all dispatchers' instructions go direct to engineer. The dispatcher can change a meeting or passing point instantly, without the least risk, simply by changing the switches in his office. Therefore, in case of delay to one train opposing trains will not waste time waiting for a meet. Extra trains and other unexpected train movement are directed with as great facility as the movements of regular trains.

Track Capacity.—Fifty per cent. more trains can be handled over a single track road, therefore the double tracking of a line may be postponed for many years. On double track roads westbound movements on the eastbound track or vice versa, are quickly arranged for.

Efficiency.—Ninety per cent. of all apparatus used is stock apparatus, simple in construction and thoroughly tested for signal and other purposes. A high degree of efficiency is therefore assured. The principal apparatus is in the dispatcher's office and under the dispatcher's immediate and direct care. The simple signal apparatus is entirely located on the locomotive or car and is subject to inspection by efficient mechanics at least once a day. Line wire and third rails are the only part of the system installed along the roadway, and are subject to few failures since they contain no moving parts. Lightning troubles cause no delay because all fuses and arresters are placed in the dispatcher's office and can promptly be replaced when burnt out. Trains are directed both by signal and telephone, therefore a complete tie-up is not possible unless both signal and telephone apparatus are out of order at the same time.

Discipline.—The automatic record in the dispatcher's office serves two purposes. It gives the dispatcher the fullest possible knowledge as to the whereabouts of all trains, etc., and enables him to direct very perfectly all train movements; and in addition to this it serves as a permanent record of many important acts of the train crews, such as a train running behind or ahead of schedule; the speed maintained through any block; length of delays; the efficiency of dispatcher in directing train movements, etc. This information is all recorded in graphic form and a few minutes perusal by the superintendent of each day's record will enable him promptly and justly to correct any weakness in his organization.

Economy.—The first cost is far less than the automatic block system and is in direct proportion to the amount of traffic. Maintenance expense is low because no specially trained men are needed to look after the apparatus along the track. Dispatchers maintain the office equipment, and roundhouse or barn men the signal equipment. Roads now using the manual block system will save a large amount in operating expense by the elimination of block operators, and will find that expenses, arising from overtime to crews of delayed trains, are much reduced.

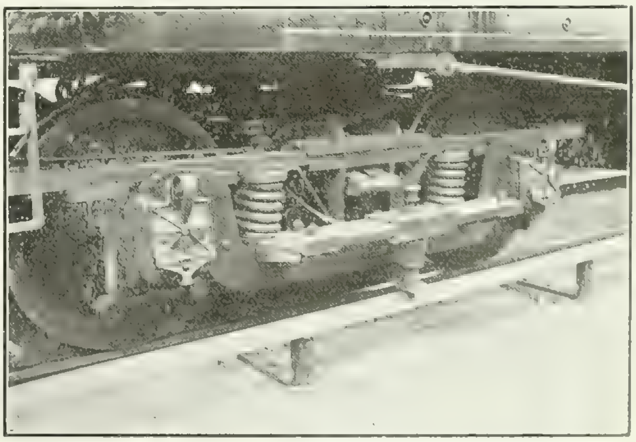

Fig. 3.—Showing Contact Shoe on Third Rail. (Cap Removed to Show Contact Detail.)

Description of the Simmen System.

The elements which enter into the system may be divided as follows:—

(1) A record sheet of train movements in graphic form.

(2) An automatic means for the recording of train movements upon the sheet.

(3) A means by which the dispatcher can display "danger" and "clear" signals on moving trains (or any other type of signals).

(4) A direct telephone connection between the engineer, on his engine, and the dispatcher.

(5) A new, simple, inexpensive and effective cab signal.

(6) An inexpensive automatic stop, based on a new principle, by which the stops and proper speeds are enforced over every foot of the road.

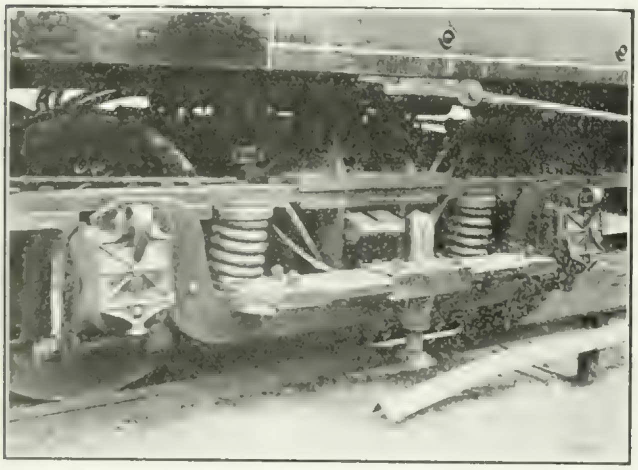

Fig. 4.—Shoe About to Make Contact on Third Rail.

Dispatcher's Record Sheet.—The record sheet is divided into time lines in one direction (10 a.m., 10.20 a.m., etc.) and block lines in the other, (e.g., Sunnyside, Humber, Mimico, Long Branch, etc.). (Figs. 1 and 2). On a single track road, blocks usually run from passing siding to passing siding and are spaced on the sheet proportionately to their length.

Each day a new record sheet is placed upon the dispatcher's recording table. The recording table is provided with clock-work for continuously moving the sheet, and with electrically operated perforating needles. Two such perforating [illegible] are provided for each block, one recording eastbound movements and the other westbound. The record sheet, when placed, is regularly and continuously moved by clockwork, so that the correct time line, as marked upon the sheet, is always directly under the perforating needles.

[illegible]

[illegible]

[illegible]

An Automatic Means for the Recording of Train Movements Upon the Dispatcher's Sheet.—At every siding along the road there will usually be four "third" rails placed at suitable locations. These third rails are insulated from the track and their length depends upon the speeds attained upon the particular road. For fast traffic they are from 70 to 80 feet long. Two of these rails are for the direction of westbound movements and two for eastbound. One "eastbound" rail is placed near the beginning of a block, and is known as the "home rail." The other is placed at a point one to two thousand feet back from the beginning of a new block and is known as the "distant rail." Similarly with the "westbound" rails.

A locomotive or motor car is provided with a shoe which makes an electrical contact with the third rails when sliding over them. (Figs. 3 and 4). When a shoe is in contact with a third rail, the (normally) open circuit between the third rail and track, is closed, the closed circuit then running from third rail through the contact shoe, and apparatus on cab, to a ground return on the truck and track rails.

The third rails (home rails) at siding are connected by wire to dispatcher's office and there are connected to one side of the dispatcher's switch.

From the other side of the dispatcher's switch a wire connects through the winding of the main relay to the pole of the storage battery, the other pole of the storage battery being connected to ground at track rails. The instant a contact shoe on a train makes contact with a third rail a circuit is established as follows. From storage battery in the dispatcher's office, through wire, main relay, dispatcher's switch, wire, third rail, contact shoe, signal relay on cab, ground on truck, and track rail, back to dispatcher's battery. The closing of this main circuit energizes the main relay which in turn closes a local circuit through the perforating magnet as follows:—

From storage battery through wire, perforating magnet, armature of main relay, to negative side of storage battery. The perforating magnet, being energized, acts on its armature, which forces the perforating needle upwards, thus perforating the dispatcher's record sheet and recording upon it the time and place of a train passing siding. The perforating circuits provide only for a single punch upon the recording sheet when a train is passing a third rail. To

Fig. 5.—Motorman in Cab. (Shows Position of Red and Green Lights.)

give continuous perforation as long as a train is in the block, a polarized relay is used.

Signalling Means.—A new type of cab signal has been developed which, by means of inexpensive intermittent third rails, gives as complete signal information as can be accomplished by a continuous third (signal) rail. The underlying principle of the cab signal is that if a third rail is electrically energized, a train in passing will receive a clear signal; if the third rail is de-energized a danger signal is displayed. Furthermore, a clear signal received in entering a new block will continue to show clear throughout the block, and a danger signal once displayed will continue at danger until it is automatically cleared when a train is passing an energized third rail. Either a clear or a danger signal is always in evidence every foot of the way. The cab signal circuit is shown in Fig. 6, and Fig. 5 shows motorman in cab with position of red and green lights. The third rail has inclined approaches at each end. When the contact shoe approaches the third rail the shoe is raised and the arm of the contact shoe separates from the front stop.

If so desired a bell can be inserted into the danger circuit so that both visible and audible danger signals will be given. This bell gives one tap each time a third rail is passed, thus calling the attention of the engineer to a possible change of signals, as well as being a positive signal that the cab equipment is in perfect operating condition.

When a third rail is energized a clear signal is displayed; when de-energized, a danger signal is displayed. Since the dispatcher's switch controlling the signals at siding is closed, it is evident that the third rails at siding are energized, and therefore set for a clear signal. To display a danger or stop signal at siding the dispatcher simply opens switch, thus depriving the third rails of electrical energy from the storage battery.

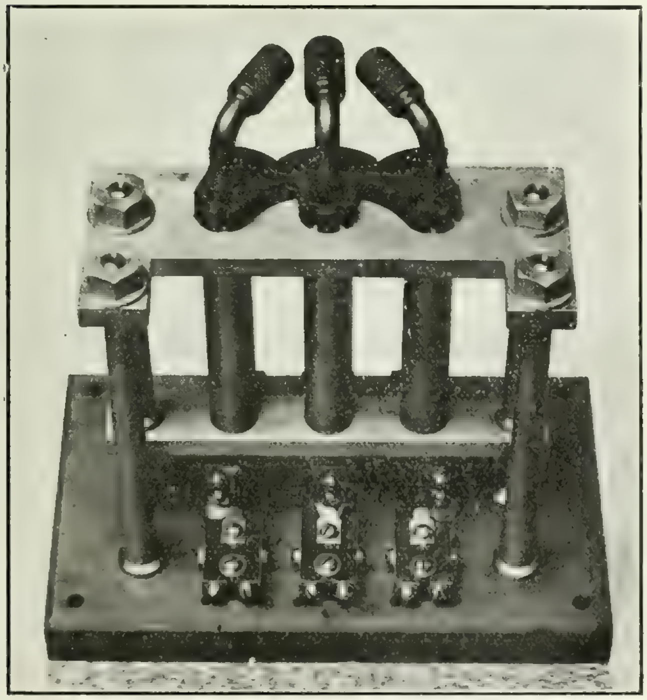

Fig. 7.—Unit of Three Switches.

Interlocking arrangements on the dispatcher's switchboard prevent the dispatcher from giving a clear signal to an eastbound train entering a block until the signal for the westbound train at the opposite end of the block is set to danger.

Only the broad essentials of the circuits and their functions have been described. Various modifications and combinations with the present signalling methods are possible, by which any special traffic requirements can be met. Telephone communications are established over the same circuit as is used for signalling, the telephone apparatus being placed in shunt with the same and provided with condensers. Fig. 7 is a photograph of a unit of three switches.

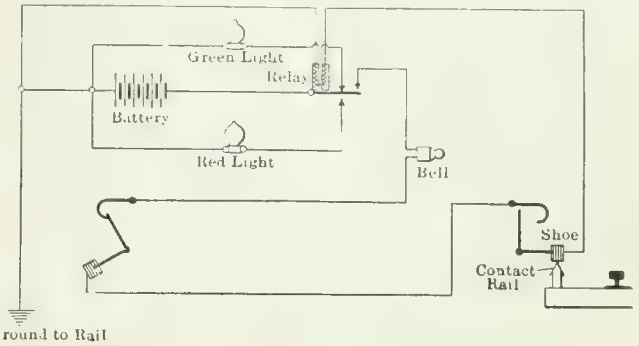

Fig. 6.—Diagram of Car Circuit.

The Simmen automatic stop provides for the automatic application of air brakes under the following conditions:—

(a) Where danger signals have been given but not obeyed.

(b) Where proper speeds at curves, grades, yard limits, or grade crossings are not observed.

(c) Where reduced speed for permissive or backward movements are not observed.

* * *

NEW WAREHOUSES OF THE NEW ENGLAND WASTE COMPANY.

The warehouse and waste plant of the New England Waste Co., at Revere, Mass., is an unusually attractive reinforced concrete building. The architects and engineers, Lockwood, Greene & Co., of Boston, specified the use of brick curtain walls, which make an effective and pleasing contrast with the concrete. The building is located adjacent to the tracks of the Boston & Maine Railroad, rendering excellent facilities for shipping.

This structure is 180 by 56 feet, four stories high with basement, and has a projecting tower on the front enclosing stairs, laboratories, and boiler for heating. As is usual with concrete, maximum window area has been obtained. The building is equipped with automatic whip hoist trolley conveyors and baling presses.

The floors of this building were designed to carry a live load of 150 lbs. per square foot. The column spacing is 20 by 18 feet, and the height of stories is 14 feet. It is interesting to note in this connection that although the floors were designed for 150 lbs. live load they were only slightly damaged by the accidental falling of a 4,000 lb. weight. On the second floor was located a baling press with plunger running through the third floor and counterbalanced by a 4,000 lb. weight made up of pieces of cast iron. The weight was suspended from the fourth floor by a through bolt with hook and pulley attached. The rope parted and the 4,000 lb. weight fell to the floor through a distance of 8½ feet. The only damage done to the concrete was a flaking of a space of about 20 inches in diameter on the under side of the floor.

The building was erected by the New England Concrete Construction Co., of Boston, and the methods employed by them in handling the materials and concrete are of unusual interest. The aggregates for the concrete were handled mechanically from the time they left the railroad cars until they were dumped into the mixer. The concrete, after being hoisted to a sufficient elevation, was distributed through spouts to the various forms.

The practice of placing concrete by spouts instead of by carts or wheelbarrows, while not unusual is still not common. Where the job is large enough it is a most economical way to handle concrete. On the work in question the amount of concrete used was approximately 3,000 yards and the contractors report that they placed concrete rapidly and at a very low cost with the plant adopted.

This warehouse of the New England Waste Co. presents a convincing answer to the argument that reinforced concrete buildings are unsightly. This structure is of excellent design and its appearance is more excellent than could be obtained in the ordinary brick and timber construction.

◆

PROGRAMME CANADIAN PUBLIC HEALTH ASSOCIATION.

The Canadian Public Health Association convention will be held in Toronto September 16th, 17th and 18th, 1912, at the University of Toronto. The following is the programme:

Monday, September 16th.

Physics Building, Toronto University.

10 a.m. to 11 a.m.—General opening business meeting, [illegible]

General session, room 43: 11 a.m. to 11.30 a.m.—"How Shall Canada Save Her People from the Physical and Mental Degeneracy Due to Industrialism as Seen in the Great Cities of Older Civilization?" Dr. P. H. Bryce, seperintendent of immigration, Ottawa.

11.30 a.m. to 12.30 p.m.—Symposium. "Tuberculosis," Dr. J. H. Elliot, Toronto.

Discussion—Dr. G. D. Porter, Toronto; Dr. Harold Parsons, Toronto; Dr. W. B. Kendall, Muskoka Sanatorium; Dr. C. D. Parfitt, Gravenhurst; Miss Dyke, Toronto; and others.

12.30 p.m. to 1 p.m.—"Prevention of Tuberculosis in the Country," Dr. H. G. Roberts, Guelph, Ont.

2.30 to 3 p.m.—"Hospitals, Their Relation to the Community and Public Health," Dr. Bruce Smith, inspector of prisons and public charities for Ontario.

3 p.m. to 3.30 p.m.—"Dust in the House and in the Street," Dr. Adam Wright, chairman Ontario Board of Health

3.30 p.m. to 4 p.m.—"The Ontario Public Health Act," Dr. John W. S. McCullough, chief health officer for Ontario.

[illegible]

7.30 p.m.—Moving health pictures, Ontario Provincial Board of Health.

[illegible]

Tuesday, September 17th.

[illegible]

Section I.—"Military Hygiene," at room 30. Convenor, J. T. Fotheringham, Lieut.-Col. P.M.O., A.M.S., D.G.M.S., Canada.

[illegible]

[illegible]

11 a.m. to 11.45 a.m.—"Some Observations on Sanitation for the Soldier," T. B. Richardson, major A.M.C.

11.45 a.m. to 12.30 p.m.—"The Militia as a Factor in Public Health," Lorne Drum, major, A.M.S.

12.30 p.m. to 1 p.m.—Election of convener and committee of section.

Section II.—"Milk Inspection," at room 42. Convenor, Andrew R. B. Richmond, V.S., B.V.Sc.

9.30 a.m. to 10.15 a.m.—"Municipal Milk Inspection in Toronto," G. G. Nasmith, director of laboratories, city of Toronto.

10.15 a.m. to 11.00 a.m.—"Municipal Food Inspection," Robert Awde, chief food inspector, Toronto.

11 a.m. to 11.45 a.m.—"Dominion Meat Inspection," L. W. Wilson, in charge of Dominion meat inspection staff, Toronto.

11.45 a.m. to 12.30 p.m.—"Municipal Inspection," Andrew R. B. Richmond, chief of staff of veterinary inspectors, Toronto.

12.30 p.m. to 1.30 p.m.—Election of convenor and Committee of section.

Section III.—Engineers and Architects, room 62. Convener, T. Aird Murray, M.Can.Soc.C.E.

9.30 a.m. to 10 a.m.—"Toronto Filtration Plant," Jos. Race, bacteriologist, city of Ottawa.

10 a.m. to 10.30 a.m.—"A Complete Sewage Disposal Plant for a Public Institution," T. Lowes, C.E., Toronto.

10.30 a.m. to 11.00 a.m.—"How to Obtain Efficiency from Pressure Filters," H. W. Cowan, C.E., Toronto.

11 a.m. to 11.30 a.m.—"Housing and Ventilation," N. Couchon, C.E., Ottawa.

11.30 a.m. to 12.00 a.m.—"Storm and Surface Water Drainage in Relation to Sewage Disposal," R. R. Knight, C.E., Toronto.

12.00 a.m. to 12.30 p.m.—"The Relations Between the Medical Health Officer and the Engineer," Thos. H. Hogg, C.E., B.A.Sc., Toronto.

12.30 p.m. to 1.00 p.m.—Election of convener and committee of section.

Section IV.—Medical Officers of Health, at room No. 41. Convener, James Roberts, M.D., medical officer of health, Hamilton.

9.30 a.m. to 10.15 a.m.—"A Modern Hospital for Cummunicable Diseases," Dr. Chas. J. C. O. Hastings, medical officer of health, Toronto

10.15 a.m. to 11 a.m.—"The International Hygiene Exhibition, Dresden," Dr. J. F. Honsberger, Berlin, Ont.

11 a.m. to 11.45 a.m.—"Municipal Control of Milk Supplies," Dr. Whitelaw, medical officer of health, Edmonton, Alta.

11.45 a.m. to 12.30 p.m.—"The Importance of Trained Sanitary Inspectors," Dr. A. J. Douglas, medical officer of Health, Winnipeg, Man.

12.30 p.m. to 1.00 p.m.—Election of convener and section committee.

Section V.—Medical Inspection, at room 18. Convener, Dr. W. E. Struthers, medical inspector of schools, Toronto.

9.30 a.m. to 10 a.m.—"Tuberculosis in Children," Dr. J. H. Elliott, Toronto.

10 a.m. to 10.30 a.m.—"Nursing Side of Medical Inspection of Schools," Miss L. L. Rogers, R.N., Toronto.

10.30 a.m. to 11.00 a.m.—Lantern slides on the work of medical inspection of schools in Toronto, W. E. Struthers, B.A.M.D., Toronto.

11 a.m. to 11.30 a.m.—"The Dental Aspect of Medical Inspection of Schools," W. H. Doherty, D.D.S.

11.30 a.m. to 12 a.m.—Paper and lantern slides: "The Open Air Schools of England," A. J. Green, headmaster of Birley House Open Air School, London, Eng.

12 a.m. to 12.30 p.m.—Election of convener and section committee.

Section VI.—Social Workers. Convener, Helen MacMurchy, Toronto. (See printed list).

Section VII.—Laboratory Workers, at room 39. Convener, J. A. Amyot, M.D., Toronto.

9.30 a.m. to 10.15 a.m.—Paper, Dr. H. W. Hill, director, Institute of Pubic Health, London, Ont.

10.15 a.m. to 11 a.m.—"Vitality of Bacilli in Water Supplies," Jos. Race, bacteriologist, Ottawa.

11 a.m. to 11.45 a.m.—Paper, Dr. Revell, Provincial Board of Health, Edmonton, Alta.

11.45 a.m. to 12.30 p.m.—Paper, G. G. Nasmith, city of Toronto.

12.30 p.m. to 1 p.m.—Election of convener of section committee.

Second General Session, Room 43, 2.30 p.m. to 4.30 p.m.

2.30 p.m. to 3.00 p.m.—"Diet in Relation to Disease," Dr. H. B. Anderson, Toronto. Professor V. E. Henderson, Toronto, and Professor Fotheringham will open discussion.

3.30 p.m.—President's address, Chas. A. Hodgetts, M.D., Ottawa, Ont.

3.30 p.m. to 4.00 p.m.—Paper, Dr. W. T. Sherreff, medical officer of health, Ottawa.

4.00 p.m. to 4.30 p.m.—"A Threatened Outbreak of Typhoid Fever in Fort William and Means Taken to Avert it," Dr. R. E. Woodhouse, district officer of health.

Garden party—Sir Edmund B. Osler, 4.30 p.m. to 7.00 p.m.

Annual dinner—McConkey's, 8 p.m. Tickets at registration office, $2.

Wednesday, September 18th.

Third General Session, Room 43.

9.30 a.m. to 10.00 a.m.—Paper, Dr. H. W. Hill, director Institute of Public Health, London, Ont.

10.00 a.m. to 10.30 a.m.—"The Feeble Minded," Mr. J. P. Downey, superintendent, Asylum for Insane, Orillia.

10.30 to 11.00 a.m.—"Medical Inspection of Public Schools," Dr. A. P. Reid, provincial health officer of Nova Scotia.

11.00 a.m. to 11.30 a.m.—Symposium. "Communicable Diseases."

11.30 a.m. to 12 a.m.—Paper, Dr. H. G. Murray, Owen Sound.

12 a.m. to 12.30 p.m.—"The Value of a Public Health Laboratory to a Municipality," G. G. Nasmith, city bacteriologist, Toronto.

12.30 p.m. to 1.00 p.m.—"Of What Value are Sanatoria as a Public Health Measure?" Dr. W. B. Kendall.

1.00 p.m. to 2.00 p.m.—Adjournment.

General Session (Continued)—2.00 p.m. to 2.30 p.m.—"The Effects of Immigration on the National Health," Will. W. Lee, secretary of immigration branch of Y.M.C.A., Quebec.

2.30 a.m. to 3.00 p.m.—"The Open Window," J. Flemming Goodchild.

3.00 p.m. to 3.30 p.m.—"A Federal Public Health Department," Dr. J. L. Chabot, M.P., Ottawa.

Business meeting, 3.30 p.m.

A musicale Wednesday evening, courtesy of Col. and Mrs. A. E. Gooderham.

Arrangements will be made by courtesy of R. Harris, commissioner of works, for the members to visit the Toronto city filtration plant and sewage dispasal works.

UNION OF CANADIAN MUNICIPALITIES.

At the final session of this organization held in Windsor, Ont., August 29th, the following were elected officers for the coming season:—Mayor Hopewell, of Ottawa, president; Mayor Lavallee, of Montreal, first vice-president; Mayor Waugh, of Winnipeg, 2nd vice-president, and Mayor Beckwith, of Victoria, 3rd vice-president; W. D. Lightall, of Montreal, honorary secretary-treasurer, and G. S. Wilson, assistant secretary. The next convention will be held in Saskatoon, Sask.

RAILWAY COLLISION IN ENGLAND.

A rear collision at the Vauxhall Station of the London & Southwestern Railway, in London, England, on August 29th, resulted in the death of two and the injury of forty persons. A crowded commuters' train from Aldershot was standing in the station, when a light passenger train, consisting of a locomotive and two coaches, crashed into the rear end of it. A defective switch is blamed for the accident.

PERSONAL.

MR. J. G. MILL, until recently employed in the main drainage department of the City Engineer's office of Toronto, has been appointed resident engineer on the sewage disposal works of North Toronto.

MR. R. O. WYNNE-ROBERTS, consulting engineer, of Regina, called at the office of *The Canadian Engineer* in Toronto this week. Mr. Wynne-Roberts is on a tour of inspection of gas-works in Eastern Canada and the United States.

MR. R. H. MURRAY, A.M.I.C.E., who has been resident engineer for Mr. T. Aird Murray on the installation of sewers and sewage disposal plant for North Toronto, has been appointed resident sanitary engineer for the Province of Saskatchewan, with headquarters at Regina.

MR. R. F. PACK has been appointed general manager of the Minneapolis General Electric Company. Mr. Pack has been for several years general manager of the Toronto Electric Light Company, and has just recently resigned to accept the new position. He was elected president of the Canadian Electrical Association at the last annual meeting held in Ottawa.

MR. C. W. WARD, of Messrs. Reavell & Co., Limited, of Ipswich, Eng., returned to London this week after having been in Canada in connection with air compressors supplied to the Water Commissioners of London, Ont. The machines had been rejected by the commission because of low volumetric efficiency. Messrs. Reavell & Co., Limited, being of the opinion that a mistake had been made in testing the plant, sent Mr. Ward out to locate the trouble. The results of further tests demonstrated the efficiency of the plant, and it has been accepted without any alteration being made.

MR. JOSEPH RACE, F.I.C., has been appointed director of Laboratories for Ottawa at a salary of $2,400 per annum. Mr. Race, who has been analyst at the Toronto Filtration Plant, is well known to readers of *The Canadian Engineer*, as he has been a frequent contributor on sanitary subjects.

◆

COMING MEETINGS.

CANADIAN GAS ASSOCIATION.—Fifth annual convention will be held in Toronto, August 24th to Sept 9th, 1912, during the Exhibition. Sec'y-Treasurer, John Keillor, Hamilton, Ont.

CANADIAN FORESTRY ASSOCIATION.—Convention will be held in Victoria, B.C., Sept. 4th-6th. Secy., James Lawler, Canadian Building, Ottawa.

CANADIAN PUBLIC HEALTH ASSOCIATION.—Second Annual Meeting to be held in Toronto, Sept. 16, 17 and 18.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

EIGHTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.—Opening Meeting, Washington, D.C., September 4th, 1912. Other meetings, Business and Scientific, in New York, beginning Friday, September 6th, 1912 and ending September 13th, 1912. Secretary, Bernhard G. Hesse, Ph. D., 25 Broad Street, New York City.

INTERNATIONAL ASSOCIATION FOR TESTING MATERIALS.—Sixth Congress will be held in the Engineering Societies Building, 29 West Thirty-ninth Street, New York, Sept. 2-7, 1912 Secretary, H. F. J. Porter, 29 West Thirty-ninth Street, New York.

ILLUMINATING ENGINEERING SOCIETY.—Sixth Annual Convention to be held at Hotel Clifton, Niagra Falls, Ont., Sept. 16-19, 1912. Secretary, Preston S. Millar, 29 West Thirty-ninth Street, New York.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. The Secretary, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

◆

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 409 Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible]

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-jack. Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

[illegible] ASSOCIATION.—President, Mayor [illegible], Hamilton [illegible] St. Thomas, Ontario.

[illegible] ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, [illegible]

THE ALBERTA [illegible] ASSOCIATION.—President, [illegible]

[illegible] OF CANADIAN MUNICIPALITIES.—President, [illegible]

[illegible] MUNICIPALITIES.—President, [illegible] Secretary-Treasurer, J. W. McCready, City [illegible]

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. [illegible] Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor [illegible]

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor [illegible] Mr. H. Bose, Surrey [illegible]

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor [illegible]

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, [illegible], Man.; Secy-Treasurer, Reeve [illegible], Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer [illegible], Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. [illegible], No. 5 Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box [illegible], Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. [illegible], P.O. Box [illegible], Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

TENDERS PENDING.

In Addition to Those in this Issue.

TENDERS.

Brandon, Man. Tenders for the delivery of two return boilers and stokers, will be received by Harry Brown, City Clerk, City Hall, until noon of September 27th, 1912. Specifications, etc., may be obtained from A. W. Shaw, Engineer, Brandon. (See advt. in The Canadian Engineer).

Cobourg, Ont.—Tenders addressed to N. F. MacNachtan, county clerk, Cobourg, will be received until September 20th, 1912, for the several trades works required in the erection and completion of a hospital. Plans and specifications at the clerk's office. Messrs. Power and Son, architects, Kingston, Ont.

Franklyn Point, P.E.I.—Tenders will be received by R. C. Desrochers, secretary, Department of Public Works, Ottawa, until October 8, 1912, for the construction of a wharf at Franklyn Point, North River, Queen's County, P.E.I. Plans, etc., can be seen at the department and at the offices of J. B. Hegan, Esq., district engineer, Charlottetown, P.E.I., and on application to the postmaster at North River, P.E.I.

Guelph, Ont.—Tenders addressed to H. F. McNaughten, secretary, Department of Public Works, Toronto, Ontario, will be received until September 23rd, 1912, for all trades (excepting heating, plumbing and lighting) for the erection of Field Husbandry Building on the grounds of the Ontario Agricultural College, Guelph, Ont. Plans and specifications can be seen at this department and at the office of the superintendent at the College, Guelph.

L'Assomption, Que.—Tenders for the construction of an iron and concrete bridge over River L'Achigan, will be received until September 15th, 1913, by J. E. Duhamel, secretary-treasurer, municipal corporation of L'Assomption.

New Liskeard, Ont.—Tenders for the construction of a sewer on Broadwood Avenue and Dymond Crescent, will be received until September 16, 1912. Plans, etc., at the office of C. H. Fullerton, town engineer; J. I. Dixon, clerk.

North Vancouver, B.C.—The city council awarded the contract for the grading of Fourth Street from Mahon to St. Andrew's Avenue, to Messrs. Hall & Bowyer for $8,002.

Ottawa, Ont.—The Canadian Government has awarded to the Dublin Shipbuildinng Company, Dublin, Ireland, a contract for the construction of two fisheries protection vessels to be used in preventing United States fishermen from poaching in the waters off the west coast of Vancouver Island.

Ottawa, Ont.—Sealed tenders, addressed to L. K. Jones, Assistant Deputy-Minister and Secretary, Department of Railways and Canals, will be received up to 4 p.m. September 20th next for the supply and erection of a steel superstructure of an addition to the grain elevator at Port Colborne, Welland Canal, Ont.

Ottawa, Ont.—Sealed tenders addressed to R. C. Desrocher, Secretary, Department of Public Works, will be received up to 4 p.m., on Wednesday, October 2nd next, for the construction of a timber superstructure of a wharf on part of the Tunnel Bay dock at Brockville, Leeds County, Ont. Plans, etc., may be obtained at this Department and at the offices of S. J. Chapleau, Esq., District Engineer, Corry Building, Ottawa, Ont.; J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont.; and on application to the Postmaster at Brockville, Ont.

Ottawa, Ont.—Sealed tenders, addresses to Eugene Fiset, Colonel, Deputy-Minister, Department of Militia and Defence, will be received up to noon, September 18th, 1912, for the construction of a new drill hall at Lindsay, Ont. Specifications may be seen and full particulars obtained at the offices of the Officer Commanding the 3rd Division, Kingston, Ont.; Officer Commanding the 45th Victoria Regiment, the Town Clerk, Lindsay, Ont., and the Director of Engineer Services, Headquarters, Ottawa.

Penetanguishene, Ont.—Tenders for dredging required here will be received until September 13, 1912, at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa. Specifications, etc., may be obtained on application to the secretary of Public Works, Ottawa.

Powell River, B.C.—Tenders for the erection and completion of a school house at Powell River, in the Comox district, B.C., will be received until September 18, 1912, plans and specifications of which may be seen at the offices of the secretary of the School Board, Powell River, B.C.; the Government agents, Vancouver, Nanaimo and Cumberland, and the Department of Public Works, Parliament Buildings, Victoria.

Regina, Sask.—Sealed tenders, endorsed "Tender for Construction of Powerhouse, Laundry and Refrigerating Plant, Regina General Hospital," and addressed to the City Commissioners, Regina, will be received until noon, Saturday, September 17th, 1912. Full particulars may be obtained upon application to Edgar I. Wenger, Consulting Engineer, Whitmore Building, Regina.

Sutherland, Sask.—Tenders for the erection and installation of a plumbing, heating and ventilating system to be installed in the public school at Sutherland, will be received until September 16, 1912, by the secretary of the Saskatoon School Board. Plans and specifications can be seen at the office of the architect, and at the Builders' Exchange, Winnipeg.

Toronto, Ont.—Tenders for plastering at the building of the Main Drainage Pumping Station will be received by registered post addressed to G. R. Geary, (Mayor), Chairman Board of Control, City Hall, Toronto, up to noon on September 11th next. Plans may be seen and full information secured at the offices of the Municipal Architect, City Hall.

Wallaceburg, Ont.—Tenders for all trades required in the erection of a bank building to be erected at Wallaceburg, will be received until September 14, 1912. Merchants Bank of Canada, proprietors. Drawings, etc., at the offices of J. L. Wilson and Son, architects, Market Building, Chatham, Ont.

◆

CONTRACTS AWARDED.

Boswell, B.C.—Pile bent wharf; H. Perry Leak, of Nelson, B.C.

Carr's Brook, N.S.—Breakwater wharf; Messrs. Halle Bigelow, of Canning, N.S.

Fairville, N.B.—Postoffice fittings; the J. T. Schell Company, of Alexandria, Ont.

Lethbridge, Alta.—Public building; contractors, Navin Brothers, of Moose Jaw, Sask.

Moose Jaw, Sask.—The contract for the construction of a bridge and dam to cost $75,000, has been awarded to Messrs. W. M. Newman and Co., 410 Ashdown Block, Winnipeg. The steel work will be done by the C. A. P. Turner Co., of Winnipeg.

Montreal.—The Grand Trunk Railway have placed a contract with John S. Metcalf Company, Limited, Montreal and Chicago, for a freight warehouse at Point St. Charles, Montreal, Quebec, 1,200 feet long and 60 feet wide; concrete foundations, brick walls and steel posts with wooden doors and [illegible]

Murray Bay, Que.—Wharf; general contractor, Nap Trudel, Ste. Irene, county of Charlevoix; estimated cost, [illegible]

Saanich, B.C. The tender of Messrs. Brown and Sim- [illegible] council.

St. Catharines, Ont. [illegible]

Victoria, B.C. [illegible]

Victoria, B.C. [illegible]

[illegible], B.C. [illegible]

for use in connecting the fire alarm signal boxes at a price of $12.28 per hundredweight.

Welland, Ont.—Mr. John Thew has been awarded a contract to erect an extension to the building of Trinity Church. This work is to cost about $8,200.

Winnipeg, Man.—Cedar for block paving; Mahoney Brothers, Winnipeg, at $10.50 per cord.

◆

RAILWAYS—STEAM AND ELECTRIC.

Kingston, Ont.—The management of the Canadian Locomotive Company have recently received an order for the construction of the following locomotives: Twenty-five heavy consolidated superheater locomotives for the Canadian Northern Railway; twenty switching locomotives for the same concern and twenty-five simple ten-wheeled locomotives for use on the lines of the Canadian Pacific Railway.

Montreal, P.Q.—A report states that the Canadian Pacific Railway engineers are preparing to construct a double track tunnel through the Selkirk Mountains at a high altitude in order that certain dangerous grades may be eliminated over Rogers pass, the scene of many serious snow slides. This tunnel, according to the report, is to be eight miles in length.

Northern Ontario.—A report states that the Commissioners of the Toronto and Northern Ontario Railway are about to electrify one of the double tracks of the line between North Cobalt and Cobalt.

Regina, Sask.—It is reported that the street railway committee of the municipal council are planning to spend the sum of $600,000 on improvements to the system during the next few months.

◆

LIGHT, HEAT AND POWER.

Berlin, Ont.—The ratepayers residing on Heinz Avenue are making enquiries regarding the cost of an ornamental lighting standard installation. They state that they desire the system installed by the coming winter.

Humboldt, Sask.—The ratepayers recently endorsed a by-law calling for the expenditure of $30,000 on an electric light plant for the municipality. Tungsten standards are to be used for the street lighting.

Montreal, P.Q.—The municipal council will consider a by-law which, if passed, will allow electric signs to project over the sidewalk for a space of six feet. The present allowance is restricted to four feet.

Ottawa, Ont.—Messrs. Harty and O'Connor have filed a claim against the Hydro-Electric Commission for a sum approximately $3,000,000 for damages arising out of the expropriation of the Chats Falls Property. In 1883 and 1911 two pieces of property which monopolize the power producing facilities of the falls were granted by the Government and the cost to the owners mentioned above is stated to be less than $2,000.

Richmond Hill, Ont.—The management of the Metropolitan Railway has made an offer to supply this municipality with electrical energy for the operation of their street lighting system, etc., at a price reported to be $25.50 per h.p.

Vancouver, B.C. -- The British Columbia Telephone Company will soon be in receipt of a shipment from Great Britain in the form of what is stated to be the heaviest telephone cable in the Dominion of Canada. It will contain [illegible] The cable is to be laid across the floor of the ocean and connect this city and North Vancouver.

◆

GARBAGE, SEWAGE AND WATER.

Calgary, Alta. [illegible]

Barrett Specification Roofs

On Four Great Granaries

To cover the four huge granaries illustrated herewith the Canadian Pacific R. R. engineers chose Barrett Specification Roofs for good and sufficient reasons.

These practical men know that these roofs will last *20 years or more.*

They further know that they will need no painting or maintenance expense of any kind and that the net cost per year of service will be infinitely lower than could be shown by any other type of roofing.

It is for these very reasons that Barrett Specification Roofs are used on more first-class buildings in the United States and Canada than any other kind

A big roof generally means a Barrett Specification Roof, for the reason that the cost of big roofs is carefully scrutinized and ultimate economy carefully considered. Small roof areas ought also to have Barrett Specification Roofs, because they are just as economical and satisfactory there.

Copy of The Barrett Specification with tracings ready for incorporation into building plans free on request. Address nearest office.

Special Note

We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired however, the following is suggested:

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15th, 1911, using the materials specified, and subject to the inspection requirements.

THE PATERSON MANUFACTURING CO., Limited
MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.

Kenora, Ont.—The town of Kenora have authorized Mr. T. Aird Murray, Consulting Engineer, Toronto, to proceed with the preparation of plans and specifications for a municipal sewer system and sewage disposal plant, and have named his fee for this work as $3,000.

McLeod, Alta.—Plans and specifications for sewage disposal, prepared by T. Aird Murray, of Toronto, have been passed by the Alberta Provincial Board of Health. The works are to be for complete purification at an estimated cost of $40,000.

Moose Jaw, Sask.—The recent action on the part of the contractors laying the water mains for the Caron water scheme in throwing up their contract will, in all probability, prove of serious consequence to the ratepayers and citizens. An engineer on the ground has advocated that a temporary line of pipe be laid at an estimated cost of $10,000. It is estimated that the permanent acqueduct cannot be finished [illegible] in.

Niagara Falls, Ont.—The by-law calling for the expenditure of $7,500 on pumping equipment was carried by the ratepayers.

Sarnia, Ont.—A report states that the intake pipe of the waterworks system is again broken in two places about 200 feet from the shore. Chlorination has been adopted, and by this means it is hoped to secure freedom from an out-break of water-borne diseases.

St. Catharines, Ont.—According to recent compilations the cost of water in this city is the third lowest of any municipality in the province possessing a waterworks system. The town of Cornwall has a supply at the lowest rate; there the cost of 1,000 gallons is 1.07 cents. Niagara Falls occupies second place with a slightly higher cost of 2.03 cents for 1,000 gallons. Then ranks St. Catharines where the cost is 2.40 cents for 1,000 gallons. In Gravenhurst the cost is 17 cents for 1,000 gallons. This is the highest price of any municipality in the province.

Yorkton, Sask.—The town engineer, Mr. Talbot-Crosbie, has under preparation a set of plans showing a method of securing a suitable supply of water for this municipality. Test wells are being sunk and should these be inefficient the supply will be secured from York Lake. If the lake is resorted to it is proposed to take the water from a ravine by gravitation or pumping, through a filtration system into a storage reservoir with a capacity of at least 100,000 gallons.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Aurora, Ont.—[illegible] Cockerill Company, office furniture manufacturers, have been granted assistance from the ratepayers of this municipality and will [illegible]. The present [illegible].

Edmonton, Alta.—[illegible] the city by the Grand Trunk Pacific Railway will be a seven story structure with full basement, 185 by 250 feet, of steel, concrete re-[illegible]

Galt, Ont.—[illegible]

Montreal, P.Q.—[illegible]

Saskatoon, Sask.—The management of the Metal Shingle and Siding Company, of Preston, Ont., will erect a branch factory in this city. It is reported that the cost of this factory will be $100,000.

St. Thomas, Ont.—There is a probability of the E. T. Wright Shoe Company, of Massachusetts, building a branch factory in this city. They have asked that the city provide them with a modern brick or concrete factory with basement, elevators, vaults, etc. A by-law will be submitted to the ratepayers.

Toronto, Ont.—A company has been formed with the object of opening steel works yards at the foot of Bathurst Street in the property formerly occupied by the Canadian Shipbuilding Company. It is the intention of the new company to reopen the works without delay. Several hundred men will be employed in the manufacture of structural steel. The company will also engage in tank and kindred work at first, but they will eventually branch out into marine work on a large scale. Mr. J. E. Russell, of Toronto, is interested in this new company.

Toronto, Ont.—The management of the Methodist Book Room have recently purchased a block of property on the corner of John and Richmond Streets and will erect a modern publishing house. Dr. Briggs is an official of this business.

Toronto, Ont.—As a result of a visit paid by Ald. O'Neill, chairman of the Civic Property Committee, to the industrial farm at Long Island, N.Y., buildings to cost about $70,000 are advocated for the industrial prison farms of this city on North Yonge Street.

Vancouver, B.C.—The management of the Dominion Safe Works Company recently awarded a contract for the construction of a building for the manufacture of their products. The building will be 200-ft. x 150-ft.

Victoria, B.C.—The management of the British America Trust Company will erect a two-story office building on Fort Street. Mr. Arthur E. Haynes is an official of this company.

◆

BRIDGES, ROADS AND PAVEMENTS.

Kingston, Ont.—The management of the Ontario Asphalt Block Paving Company will give a bond of guarantee and accept the contract for municipal pavements which was recently awarded them under this condition.

Toronto, Ont.—Commissioner of Works R. C. Harris has recommended that Crawford Street be paved with asphalt from College to Bloor Street. The estimated cost of this work will be $21,000.

◆

CURRENT NEWS.

Eastern Canada.—A number of tenders for the construction of a car ferry to operate between Cape Tormentine, New Brunswick and Charlottetown, Prince Edward Island, have been received by the government officials at Ottawa. The contract will be awarded with all possible dispatch as it desired to have the ferry in operation within the next few months.

Kingston, Ont.—The ratepayers of this city have been requested to subscribe the sum of $50,000 toward a fund for the erection of 100 houses to be rented to employees of the locomotive works. A company has been incorporated under the name of the Kingston Realties, Limited, with a capital of [illegible]

Kingston, Ont.—Owing to recent heavy orders being placed for completion in the shops of the Canadian Locomotive Works, [illegible], of the syndicate recently formed to build working men's houses, will call ten-[illegible] the construction of these buildings with all possible [illegible]

Regina, Sask.—Dr. M. B. Bow, municipal medical health officer, has prepared a report on a revision of this branch of the civic administration. Under the scheme of reorganization which the council will be asked to consider the department is divided into branches as follows:—Dairies; foods, fruits, etc.; plumbing and property; nuisances, infectious and contagious diseases; scavenging. For each of these departments an inspector is proposed.

St. Catharines, Ont.—The total value of the building permits for the first eight months of this year amounts to $502,810.

St. Thomas, Ont.—The ratepayers will be asked to vote and authorize the municipal council to ratify a by-law calling for the granting of a loan and other concessions to the management of the St. Thomas Biscuit Company; also a by-law calling for a loan to the management of the Erie Iron Works, [illegible]

Tofield, Alta.—The ratepayers endorsed the expenditure of the following moneys for public utilities:—Waterworks, $25,000; gas distribution, $43,000; industrial site, $20,000; hospital, $4,200; drainage, $1,000. All the by-laws carried unanimously.

Victoria, B.C.—The municipal council have received the following offers to erect two garbage collection stations. Mr. Edward Logan, $7,478 for the Queen's Avenue station, and $7,698 for Woodland Street station; Mr. John Robert, $12,568 for both stations; Mr. W. C. Stedham, $14,686 for both; Parfitt Brothers, $6,485 for the Queen's Avenue station and $6,095 for the Woodland Street station. The health committee will report upon these offers.

Welland, Ont.—The following is a tabulation of recent building statistics:—

Building permits for month of August this year....	$ 20,550
Building (including new school) for August last year	38,743

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured

Each week on this page may be found summaries of

17155—July [illegible]—Authorizing [illegible] & [illegible] Ry. to construct bridge No. 5.2 over Burnside Road, near Victoria, B.C.

17156—June 24—Authorizing C.P.R. to construct spur for Jamieson Lime Co., village of Sand Point, Ontario.

17157—July 27—Authorizing Kettle Valley Ry. to construct bridge over Okanagan River, B.C., at Penticton.

17158—Aug. 1—Authorizing C.N.R. to cross with its Goose Lake Extension Alberta, 68 highways.

17159—July 31—Authorizing Campbellford, Lake Ont. & W. Ry. to cross 5 highways between mileage 126.60 and 155.70, Ont.

17160—July 31—Authorizing G.T.R. to construct spur for Dominion Canners, Limited, town of Aylmer, Ontario.

17161—August 1—Authorizing C.L.O. & W. Ry. (C.P.R.) to cross 9 highways between mileage 177.86 and 183.45.

17162—August 1—Authorizing C.P.R. to construct spur for Golden West Brewing Company, Ltd., at Titian, Alberta.

17163—August 1—Authorizing C.L.O. & W. Ry. (C.P.R.) to cross 4 highways between mileage 121.87 and 124.83, Ontario.

17164-65—August 1—Authorizing C.P.R. to construct spur for Stag Creek Lumber Company on its Maniwaki Subdivision, Quebec, and for Carter Mather Lumber & Supply Co., Calgary, Alberta.

[illegible]—August 1—Approving C.N.O. Ry. station site at Torbolton, Twp. of Torbolton, County of Carleton, Ontario.

17167—August 2—Authorizing Twp. of Medonte, Ct. Simcoe, Ontario, to construct highway crossing over C.P.R. Sudbury-Kleinburg Branch.

[illegible]—August [illegible]—Approving drain plans for [illegible] Award Drain under G.T.R. in Twp. of Malahide, Ct. Elgin, Ontario.

17169—August 2—Authorizing C.N. Branch Lines Company to connect with its Canora-Sturgis Branch main line of C.N.R. at Canora, Sask.

[illegible]—August [illegible]—Authorizing C.N.Q. Ry. to construct across public road in Parish of St. Augustin, Ct. Two Mountains, Que.

17171—August 7—Approving location of C.N.R. through Twps. 19-15, Rges. 29-26, west 4 M., Alberta, mileage 31.40 to 65.05.

17172—August 6—Authorizing C.N.O. Ry. to cross 2 highways on its Ottawa-Capreol Line, Twp. Field, Dist. Nipissing, Ontario.

17173—August 3—Authorizing C.P.R. to construct spur to its freight sheds at New Westminster, B.C.

17174-5—August 6—Authorizing C.L.O. & W. Ry. (C.P.R.) to cross forced road from Crow Lake to Sharbot Lake, Ont., and highway in Twp. of Hamilton, Ct. Northumberland, Ontario.

17176—August 6—Authorizing G.T.P. B.L. Co. to construct spur for Pacific Pass Coal Fields, Ltd., Dist. North Alberta, Alta.

17177-78—August 3—Authorizing G.T.R. to construct siding into premises of W. S. Cook and Son, city of Belleville, Ont., and for Canadian Northern Montreal Land Co., Ltd., Parish of St. Laurent, Ct. Jacques Cartier, Que.

[illegible]—August [illegible]—Approving plans of Dominion Atlantic Ry. Co. for additional wing walls for bridge at Bridgetown, N.S., and for bridge over Avon River, at Windsor, N.S.

17181—August 6—Authorizing Kettle Valley Ry. to cross highway northwest of Penticton, B.C.

17182—August 3—Authorizing Essex Terminal Ry. and Michigan Central Ry. [illegible] Windsor, Ontario. [illegible] Order [illegible]

17183—August 6—Authorizing G.T.P. B.L. Co. to cross 12 highways on its Cutknife Branch, Saskatchewan.

17184—August 7—Authorizing G.T.P. to carry traffic from mileage 100 to 164 east of Prince Rupert, B.C.

[illegible]—August [illegible]—Authorizing C.P.R. to construct spur for G. F. Stephens & Co., Ltd., Calgary, Alberta.

[illegible]—August [illegible]—Approving plan of Michigan Central Ry. for new bridge over London Street, Windsor, Ontario.

17187—August 7—Authorizing Dominion Atlantic Ry. Company to recon[illegible] from Halifax.

You Need a Machine Like This on a Dozen Different Jobs

It's a No. 2 Knight Milling and Drilling Machine

This machine is very rigid, powerful and accurate, so that close work may be turned out with a high degree of satisfaction, and in the shortest possible time. The adjustments are quickly and easily made. On a large variety of work it is possible to make a saving of from 20 to 50 per cent. in time, as compared with other machines.

The fact that hundreds of Knight Machines are now in use in this and foreign countries proves that they are not experiments.

These machines are made in three sizes.

Briefly, the construction of the No. 2 Knight Miller is as follows:—Spindle of crucible steel, ground bearings; working surface of table, 29 × 8½ inches; feed, longitudinal and transverse; floor space, 60 × 68 inches; weight, crated for shipment, about 2,500 lbs.

The Canadian Engineer

An Engineering Weekly

NEW BRIDGE AT TRAIL, B.C.

There was recently completed for the Province of British Columbia, at Trail, B.C., a four-span through riveted truss type bridge, which contains much of interest, both in design and construction. The bridge was erected by Armstrong, Morrison & Co., Limited, of Vancouver, and was opened for traffic on May 24th, 1912. It is designed for ordinary highway traffic with paved roadway, eighteen feet in the clear. The bridge is of the truss type supported on tubular steel piers filled with concrete. Each pair of piers is joined together by sheet steel reinforced bracing, which forms a wall with two feet thickness of concrete. There are three piers; piers Nos. 2 and 3 were sunk by the pneumatic process, while pier No. 1 was built in a cofferdam. The site of the bridge is at the east end of the city of Trail. The bank on the south or city side, is of a rocky formation. The first pier and abutment have, therefore, solid rock foundation. The north bank of the river is of a sand and gravel formation, and the general level is about fourteen feet above the bridge floor elevation. This necessitated a cut of about fourteen feet and a removal of sixty-five hundred yards of material to make the approaches. The base of the north abutment, on account of the nature of the bottom, is forty-two feet below the floor level. The ground near the north shore slopes from zero at low water to a depth of thirty feet between piers 1 and 2, which is the channel proper.

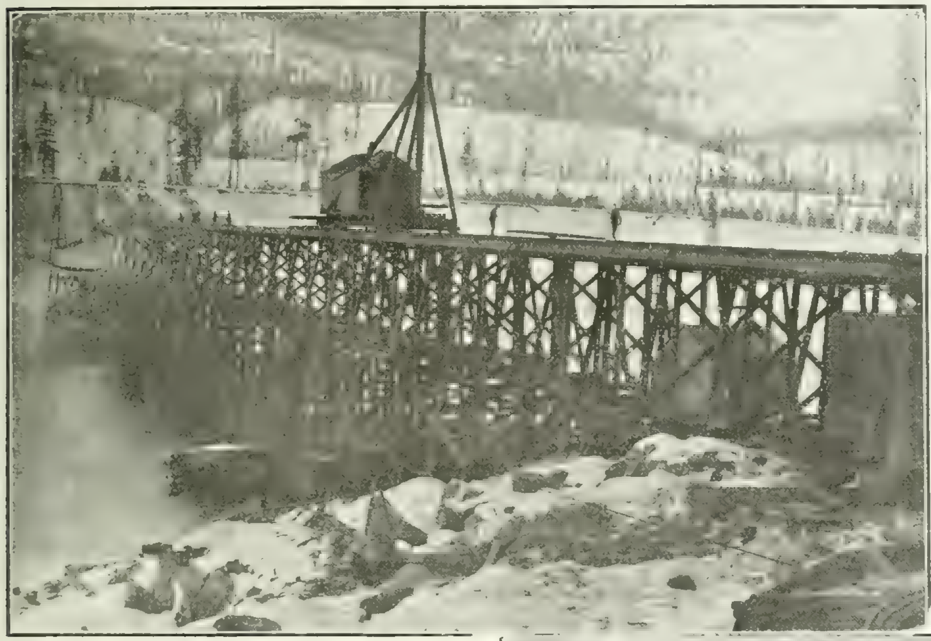

Fig. 1.—View Showing Falsework of the Bridge.

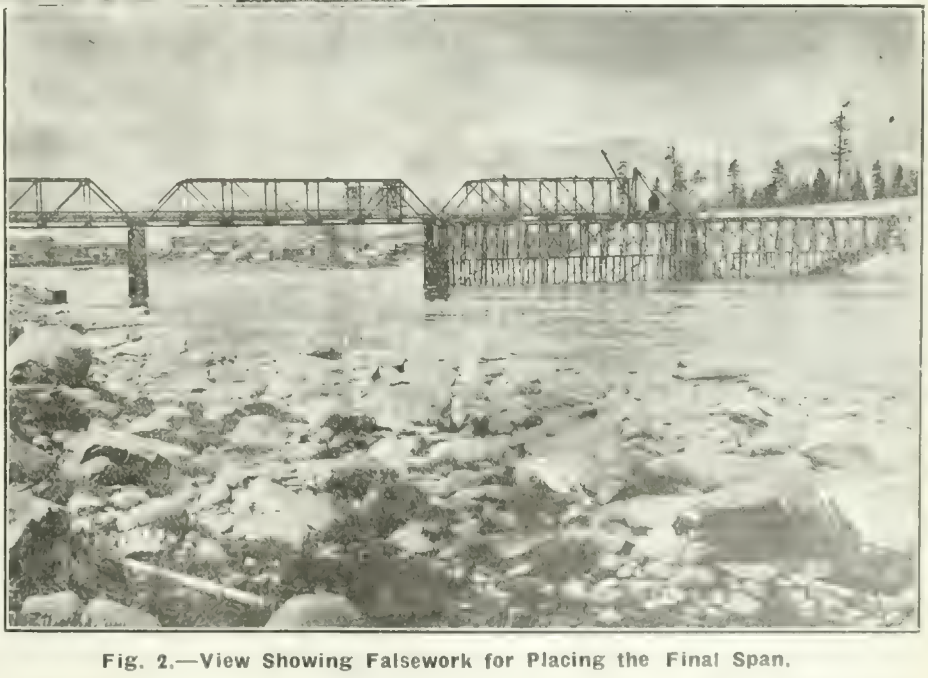

Fig. 2.—View Showing Falsework for Placing the Final Span.

Construction was commenced in November, 1911, and was completed on May 24th, 1912. Fourteen thousand lineal feet of piles were used in the falsework, and a hundred and thirty thousand feet of timber. The cement used in the construction of piers and abutments totalled about 7,500 sacks. The earth work necessitated for the approaches ran about 1,500 cubic yards. As has been noted, the bridge superstructure is made up of four spans. Each of these spans is 171 feet 6 inches in length, with seven panels to the span. The total length of the bridge is 691 feet 9 inches. The foundation of the deepest pier below low water necessitated by the nature of the ground, is 44 feet. The height of the pier over all is 86 feet. The height of the bridge from the floor to the top chord is

20 feet 6 inches, and the height from low water to top chord is 67 feet. Three hundred thousand pounds of steel were used in the piers and the weight of the steel in superstructure is 480,000 pounds. Eventually, the bridge will be provided with a lift span, but the provision of this span has been left to some future date. The lift span will be fully balanced by concrete counterweights when placed. The towers and machinery have been omitted until the river traffic requires the span to be made movable. The lift span will be operated by electric power and it will be possible to raise this to the full height of 55 feet above high water, in 60 seconds. The estimated complete cost [illegible]

The Province of British Columbia are the owners of the bridge. Waddell & Harrington, consulting engineers, Kansas City, Mo., designed the structure, while the Cleveland Bridge Company, of Darlington, Eng., were the contractors for the steel work. Armstrong, Morrison & Company, [illegible] B.C., were the [illegible] of the [illegible]

[illegible]

INTERESTING DRAINAGE SYSTEM OVER THREE THOUSAND YEARS OLD.

Dr. A. J. Evans, the chief of Cretan explorers, recently discovered the site of the Great Palace of Minos, at Knossos, near modern Candia, and the result of his explorations has brought to light the very high state of civilization enjoyed by the ancient Cretans, 3,500 years ago. The Rev. James Baikie, of Edinburg, has written a book summarizing the discoveries of Dr. Evans, entitled, "The Sea-Kings of Crete," Adams and Black, publishers (New York, The Macmillan Co.), from which the National Geographic Magazine has abstracted the following article which will be especially interesting to our readers:

Most surprising was the revelation of the amazingly complete system of drainage with which the palace was provided. The gradient of the hill which underlay the domestic quarter of the palace enabled the architect to arrange for a drainage system on a scale of completeness which is not only unparalleled in ancient times, but which it would be hard to match in Europe until a period as late as the middle of the nineteenth century of our era. A number of stone shafts, descending from the upper floors, lead to a well-built stone conduit, measuring one meter by one-half meter, whose inner surface is lined with smooth cement. These shafts serve the purpose of leading into the main con-

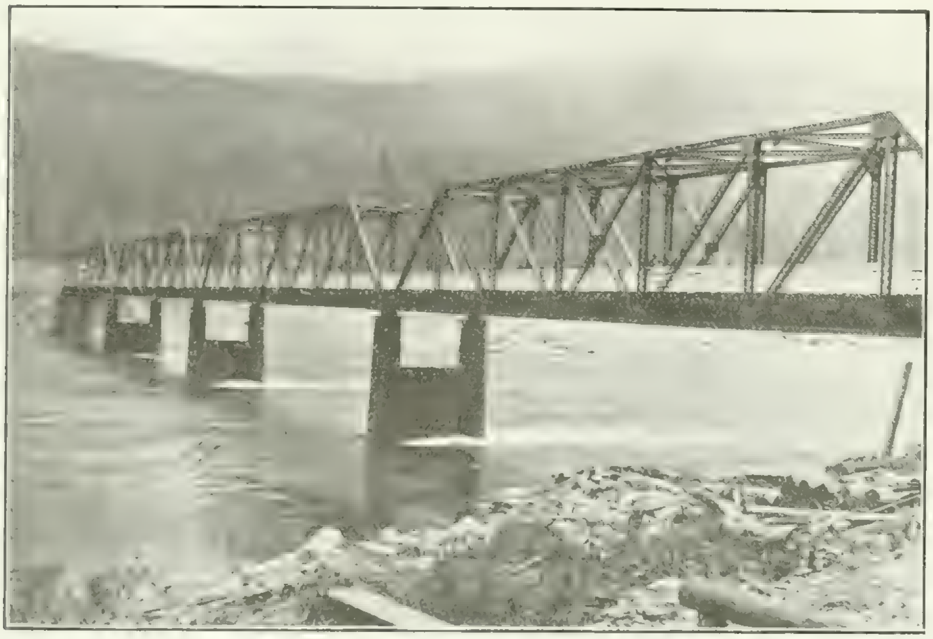

Fig. 3.—View Showing Completed Bridge.

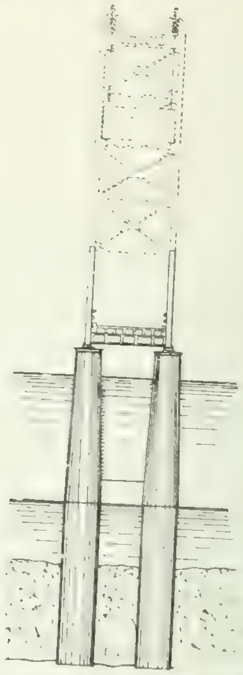
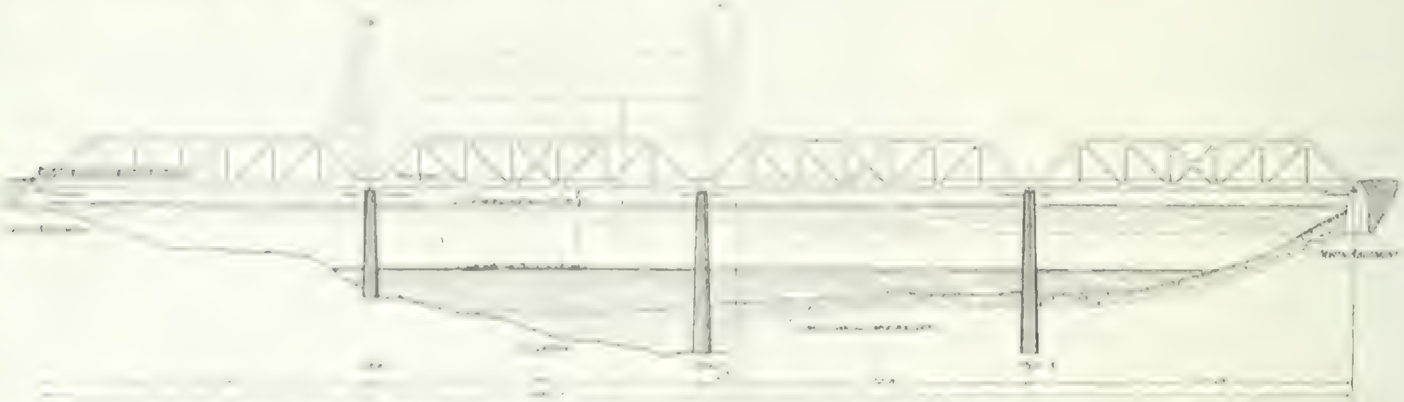


Cross Section Through Bridge.



General View of Lift Bridge at Trail, B.C. Lift Span Towers, to be Installed Later are Shown Dotted.

duit the surface water from the roofs of the palace buildings, and thus securing a periodical flushing of the drains. In connection with this surface-water system there was elaborated a system of latrines and other contrivances of a sanitary nature, which are "staggeringly modern" in their appointments.

In the northeastern quarter, under the Corridor of the Game-Board, are still preserved some of the terra-cotta pipes which served as connections to the main drain. They are actually faucet-pointed pipes of quite modern type, each section two and one-half feet in length and six inches in diameter at the wide end, and narrowing to four inches at the smaller end. Dr. Evans states that jamming was carefully prevented by a stop-ridge that ran round the outside of each narrow end a few inches from the mouth, while the inside of the butt, or broader end, was provided with a raised collar that enabled it to bear the pressure of the next pipe's stop-ridge, and gave an extra hold for the cement that bound the two pipes together.

Indeed, the hydraulic science of the Minoan architects is altogether wonderful in the completeness with which it provided for even the smallest details. On a staircase near the east bastion, on the lower part of the slope, a stone runnel for carrying off the surface water follows the line of the steps. Lest the steepness of the gradient should allow the water to descend too rapidly and flood the pavement below, the runnel is so constructed that the water follows a series of parabolic curves, and the rapidity of its fall is thus checked by friction.

The main drains are duly provided with manholes for inspection, and are so roomy that two of the Cretan workmen spent days within them clearing out the accumulated earth and rubble without inconvenience. Those who remember the many extant descriptions of the sanitary arrangements, or rather the want of sanitary arrangements, in such a town as the Edinburg of the eighteenth century will best appreciate the care and forethought with which the Minoan architects, more than 3,000 years earlier, had provided for the sanitation of the great Palace of Minos.

PRODUCTION OF ELECTRIC-FURNACE STEEL.

According to Robert Pinot, secretary-general of the Comités des Forges de France, the production of steel in electric furnaces during the last three years was, in tons:—

	1909.	1910.	1911.
Germany	17,773	36,188	66,654
United States	13,762	52,141	29,105
Austria-Hungary	9,046	20,028	22,867
France	6,456	11,759	13,850
Total	47,030	120,116	120,476

The United Kingdom had hardly commenced to produce for the general market. The predominating lead of Germany and the drop in the electric steel production of the United States are notable features of last year's figures. Activity in France lies more in the field of ferro-alloys. Of these, France made altogether, in 1904, 34,200 tons, which amount had increased to 60,200 tons by 1910; the figures for ferro-alloys made in electric furnaces were respectively 5,756 and 23,800 tons; the electrically-produced alloys amounted in 1909 to 14,900 tons, and varied little in the years 1906 to 1909.

ALGAE AND THEIR RELATION TO PUBLIC WATER SUPPLIES.

In the monthly bulletin of the Ohio State Board of Health, there is a short discussion of algae and their relation to public water supplies, by Mr. L. H. Van Buskirk, assistant engineer of the State Board of Health. The discussion follows:

The State Board of Health receives frequent requests during the summer season from different municipalities of the State, for examinations of their public water supplies in which objectionable tastes and odors have developed. It has been observed by the residents of communities so affected, and also by the State Board of Health, that the tastes and odors occur sometimes as early as April, but generally not until the latter part of May or the first of June, and that they disappear as soon as cold weather is experienced in the fall. It has also been noted that the objectionable qualities are found in water that is stored in open basins or in impounding reservoirs in which there is an opportunity for stagnation due to the heat and light of the sun and the infrequent displacement of the water; and also that the peculiarities appear and disappear almost simultaneous with the occurrence of algae. It it an interesting fact that these features are not found to any extent in waters which are stored in reservoirs from which the sunlight is excluded. Algae do not develop in the dark. It is true, however, that certain other vegetable growths which give rise to the same unpleasant qualities thrive in waters which are protected from sunlight.

It must be understood that not all tastes and odors found in water are caused by algae, for there are a large number of other agencies which effect these qualities, among which are oil wastes, salt, sulphur, organic matter, iron, and bacteria. An example of bacterial growth is crenothrix which thrives in waters containing organic matter and iron. These bacteria when present in a water cause unpleasant tastes and odors. A water supply containing crenothrix is objectionable for laundry purposes due to the effects of the iron which collects in its cells upon linen. The growth develops rapidly in the dark and is found in covered reservoirs or storage basins and in distribution systems. In public water supplies containing large amounts of iron, the bacterial growth is often seen in the water as drawn from the hydrants in the form of small red filaments. It is difficult to destroy the bacteria unless the iron is removed from the water.

A further discussion of the causes of tastes and odors will be confined to purely algal growths concerning which the following facts are given.

The appearance of algae is familiar to practically all, as there are indeed few who have not seen the green scum floating upon the surface as well as the growths along the sides and bottoms of our lakes and ponds. These latter growths are not to be mistaken for the ordinary aquatic plants which are also abundant. Many people living or visiting in a community where the water supply is stored in open reservoirs know full well what the objectionable tastes and odors are like and many have noticed the green color of the water as drawn from the tap. The same qualities are frequently observed when fire hydrants on dead ends are opened for the purpose of cleansing the mains. The algal growth discharged from dead ends must not be confused with the red crenothrix which is found much more frequently.

The simplest forms of plant life are grouped under one general heading and are called thallophytes. Thallophytes may in general be separated into two divisions known as algae and fungi. Algae are thallophytes which contain chlorophyll, the green coloring matter found in plants, and are able to manufacture food from inorganic material. They are variable in size, ranging from forms visible only by means of the microscope to salt water forms with enormously bulky bodies.

Although all algae contain chlorophyll, some of them do not appear green owing to the fact that other coloring matter is present in the cells. It is easy, therefore, to subdivide algae into groups according to their color, which variation is accompanied by constant differences in habits and methods of growth. The constant termination phyceae which appears in the names is a Greek word meaning "sea-weed," which is a common name for algae; while the prefix in each case is the Greek name for the color which characterizes the group.

The four subdivisions are as follows:

(1) Cyanophyceae, or blue green algae.
(2) Chlorophyceae, or green algae.
(3) Phaeophyceae, or brown algae.
(4) Rhodophyceae, or red algae.

The phaeophyceae and rhodophyceae are found only in salt water. Therefore, they are eliminated from consideration as affecting the fresh waters of the State. While the cyanophyceae, owing to their methods of reproduction and growth, are in some classifications not included in the algae, they are important in connection with the study of the storage of water and are accordingly placed with the algae for convenience. The cyanophyceae and chlorophyceae are therefore the important forms of algae in which we are directly interested. Each of these groups includes numerous varieties, the identification of which is sometimes difficult. By observing the characteristic color of the growth it is easy to classify the same into either of the two main subdivisions which are found in fresh water. If it is desired to ascertain the particular variety, it is necessary to use a microscope by means of which the individual cells may be observed and recognized.

The cyanophyceae give rise to grassy or moldy odors, while the chlorophyceae are characterized by a fishy or oily smell. Some of the growths appearing early in the summer are aromatic or sweetish. These odors become intensified as the algae increase in numbers and as others decay. In order that those who are not familiar with the effects of algae upon public water supply may realize to a degree the seriousness of such a condition, the following facts are given relative to a particular supply in Ohio.

The water supply of the village is obtained by impounding [illegible] near the village. The algal growths develop in the impounding reservoir each summer and are carried through [illegible]

water is stored. The growths often appear on the surface of filters, and in such cases are very difficult to remove. When the temperature of the water is from 60 to 80 degrees Fahr., the algal growth is facilitated.

The prevention of algal growths in water to be used for drinking purposes is no small problem. It has been studied by many scientists who have practically decided that copper sulphate or blue vitriol is the best substance to use. Its use, however, is attended by many complications which require that it be applied only under expert supervision. Blue vitriol is known to be highly poisonous so that great care must be exercised in its use in order to prevent sickness. Another complication attending its use is the variable amount required to destroy the different species of algae. A careful microscopic analysis is therefore necessary in order to identify the growths. Even though the algae are destroyed, the tastes and odors will not disappear unless the decaying matter is removed. In many cases the growths soon reappear and it is necessary to repeat the treatment.

Probably the safest although not always the cheapest method of protecting water supplies against algae is to provide covers for the storage basins and at the same time keep the basins clean. The presence of organic matter and light, it will be remembered, are the two most important elements promoting the growth.

In one case the growth was prevented by pumping continuously to the reservoir, allowing it to overflow. This kept the temperature low and prevented the water from becoming stagnant. This, however, is a very expensive method as large quantities of water are thereby pumped to waste.

The removal of algae from filter beds is very difficult. In one instance, where tub filters are in use, much trouble has been experienced. The filters have been scraped and treated with copper sulphate, and several times the entire filtering material has been removed and washed. The treatment, however, was not successful though large quantities of algae growth were removed. The most successful method used at this particular plant was the sterilization of the filters by means of steam.

It will be readily seen, therefore, that the presence of algae in the water supplies of the State is a serious problem and one which requires careful and serious attention. No one method of protecting a water supply as outlined above will be successful in all cases, and it is evident that a careful study should be made of each particular problem. In order to do this a consulting engineer should be retained whose duty it should be to recommend possible changes in the method of handling the supply, or who should oversee the proper treatment of the water. This is the only logical and safe method to be used in preventing or destroying algal growths and in furnishing a water suitable for domestic and drinking purposes.

DESIGN AND CONSTRUCTION OF SMOKESTACKS.

In a recent issue of Building Progress, a periodical published by the National Fire Proofing Company, of Pittsburg, there is published an article by Henry V. Feder, on "The Design and Construction of Smokestacks." A great part of the discussion deals with the use of hollow tile instead of brick for chimneys. We present herewith an abstract of the article.

To approach the problem properly, the first points to be considered are the maximum area of grate under the boilers on which coal will be burned at any time; the kind and quality of coal, and the greatest quantity of coal that will be consumed per hour per square foot of grate surface. Ordinarily twenty pounds of coal per square foot of grate surface will be the right allowance to make, although the rate of combustion will average from ten to twenty pounds per square foot of grate surface, with an average of about fifteen. The maximum, however, is what must be provided for, consequently the smokestack must be made large enough to take care of the gases of combustion during forced firing.

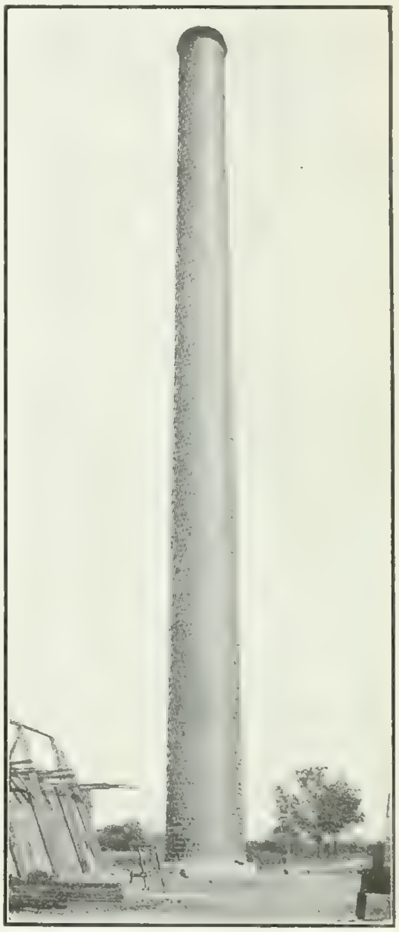
There are two—yes, three—important points outside of the stability of the smokestack to be carefully worked out by the designer. They are the height of the stack, its area and wall insulation. Taking up first the area of the stack brings us back to the combustion of coal on the grate. For the economical combustion of coal each pound must have from 143 to 169 cubic feet of free air to burn it, and this will necessitate an area capable of taking care of from 155 to 170 cubic feet of chimney gas per hour per square foot of grate surface on an average, and a much larger quantity than that when coal is first put on the fire.

If the chimney lacks either in area or in height to take care of this volume of gas, the effect will be much the same as though the air were not supplied to the coal, for a feeble fire will result, and there will be the additional annoyance of more smoke than when the stack is of sufficient size to furnish a supply of air for the combustion of the gases which cause the smoke.

Height of chimney comes next, for without height there will be insufficient draft, and the gases will not escape fast enough, even with a smokestack of enlarged area. The draft of a chimney, or the velocity of gases through it, depends entirely on the difference in weight between the column of gases in the smokestack and an equal column of air outside of the stack. The hotter the gases in the stack the greater the difference in weight between this column and a column of the air outside, and so long as the temperature of these two columns are different it stands to reason that the higher the stack the greater the total difference in weight will be. In engineering practice it is assumed that the hot gases from the boiler at the uptake where they enter the smokestack will have a temperature of 450 deg. Fahrenheit. Without this temperature the desired draft will not be attained, for, owing to the large area of exposed surface to the smokestack, loss of heat by radiation and conduction will lower the inside temperature of the stack to such an extent that the upward movement of gases will be sluggish.

This brings us naturally to the third consideration in smokestack design, the wall insulation. To keep down to the lowest possible limit the loss of heat through the walls of the stack, they should be made as heat retarding as possible, and, as nothing is quite so good as a practical insulator against loss of heat as air cells, hollow walls or compartments of some kind are commonly used for this purpose. The walls of the stack, however, have to do more with the structural design, which will be explained later.

In smokestack design the proportions of the stack must first be obtained. It might be well to explain here that chimney draft is affected by so many varying conditions that no absolutely reliable and infallible rule or formula has ever been devised for proportioning smokestacks for a certain desired draft pressure. The type of boiler, kind and size of grate, size and kind of coal to be used, frictional resistance of the smoke connections, number and size of boiler flues—these all have more or less effect on chimney draft. While absolutely accurate results cannot be obtained by rules and formula, approximate results, which, when interpreted in connection with all the modifying circumstances, will yield accurate results, can be obtained by rule, while for ready reference practice has established certain well-defined proportions for smokestacks to be used in connection with boilers of different-rated horsepowers. In the table appearing on the following page the heights of chimneys, their diameters and areas can be found for any size of boiler, or battery of boilers, from 23 horsepower to 5,031 horsepower. These proportions will be found safe for all ordinary conditions.



Hollow Tile Smokestack at the Plant of the National Fire Proofing Company of Canada, Limited, Near Hamilton Ontario.

When the height of smokestack and area of flue are known there still remain the structural features of design and construction to be worked out. For example, what should be the diameter of a smokestack at its base when it is 175 feet high?

There is a simple empirical rule that a smokestack in order to be stable must have a diameter at its base of from one-tenth to one-twelfth of its height. If in place, subject to an open, exposed strong winds, or on a floating foundation on poor soil, a diameter of one-tenth would be about right, while if the footings rested on bedrock, and the stack is partially sheltered from strong winds, the stack could be narrower at the base, perhaps one-twelfth the height of the stack being sufficient. Any proportion between these two extremes may be used, the designer being guided by judgment in assuming the proportions.

Applying this rule and assuming a height of 175 feet on a floating foundation of hard-packed sand or dry clay, the proportion of one-tenth the height may safely be taken as the diameter of the stack at the base. One-tenth the height is 17½ feet, which would be the proportion in such a case.

But smokestacks are not of uniform diameter throughout their entire heights, but grow smaller toward their tops. This batter gives them greater stability, while at the same time, by decreasing the amount of surface exposed to the strong winds, reduces the heat loss from the walls.

The batter of tall smokestacks is generally made .3 of an inch to the foot, which in a chimney 175 feet high would amount to 4 feet 4½ inches, making the chimney 8 feet 9 inches less in diameter at the top than at the bottom.

If a smokestack, rearing its top one hundred to two hundred feet in the air, is to maintain its stability, it must have walls of sufficient strength and thickness to bear the weight and resist any storms that blow. Naturally, the walls are not of uniform thickness, but increase in thickness at the base, according to the height. Common practice is to make the top 25 feet of smokestack less than 4½ feet in diameter at the top, 8 inches thick, and increase 4 inches in thickness for each 25 feet toward the base. Smokestacks over 4½ feet in diameter at the top are made 12 inches thick for the top 25 feet, and are increased in thickness 4 inches for every additional 25 feet toward the base. According to this pratice a stack 175 feet high and over 4½ feet in diameter at the top would have walls 12 inches thick for the top 25 feet, and by increasing 4 inches in each additional 25 feet would have walls 36 inches thick from the foundation to 25 feet above the ground level.

Table of Size of Chimneys for Power Plants.

Diameter Inches	Height of Chimneys and Commercial Horsepower											Side of Square Chimney Inches	Effective Area Square Feet	Actual Area Square Feet
	50 Feet	60 Feet	70 Feet	80 Feet	90 Feet	100 Feet	110 Feet	125 Feet	150 Feet	175 Feet	200 Feet

Owing to the stepping of the walls of the flue inside, and the batter given the walls of the smokestack, there would be a rough, uneven surface presented to the hot gases, and this rough interior would not be of uniform bore throughout its entire extent, a condition which would greatly [illegible] the draft of the flue [illegible] heat would be lost from the smokestack. To overcome all these objections, smokestacks are built with an interior lining of firebrick. This interior [illegible] built into the inner and outer shafts. From the middle of the stack to the top these brace walls are built into the outer shaft, but are sometimes free of the inner shaft by about one inch, like floating ribs.

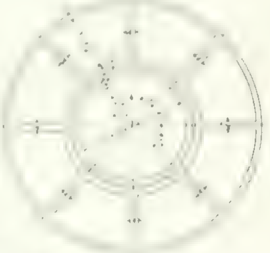
Cross Section B.B.



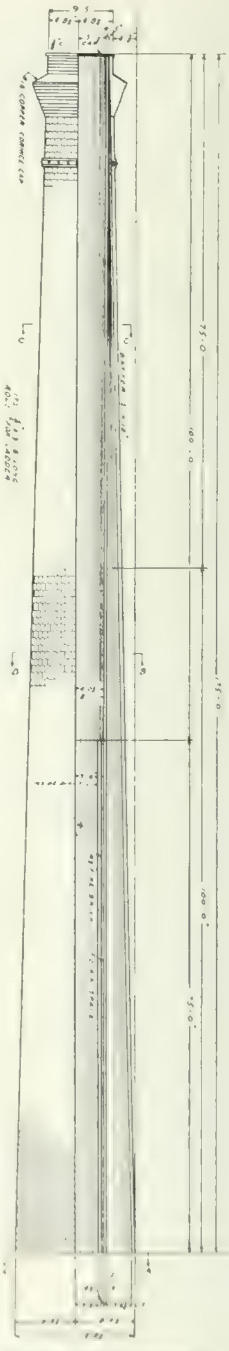
Cross Section A.A.

In the designing of the foundation or footing for a smokestack, particularly when the foundation is to be a floating one, is where great care must be exercised. The necessity for this great care will be realized when it is remembered that there are two distinct movements common to all tall, heavy structures, and that those two movements must be reduced to the lowest possible limits. Every heavy building erected on a footing other than bedrock settles into the ground from 3 to 5 inches, due to the compressibility of the soil. In Chicago, for instance, there are many prominent examples of such settlements, and provision is always made to guard against damage resulting therefrom. The Great Northern Hotel, for example, is partially carried on jacks and periodically leveled up as settlements occur.

The other movement of tall buildings erected on floating foundations, or, indeed, on any kind of footings, is found in the same city in the leaning of buildings out of plumb, the amount of the leaning in some cases amounting to a great many inches.

These two movements, then, can be considered as probable to a greater or less extent in smokestack construction, for the stacks are both tall and heavy, the extent of the movements depending to a great extent on the weight of the stack and the proportion of the footing supporting it. To reduce these movements to the minimum the footings must be liberally proportioned to the weight of the stack and the bearing capacity of the soil, so that the weight imposed on a unit area of the soil will be well within its safe limit. In compact sand and hard clay the footings or foundation at the base of the stack ought to have a diameter of about one-seventh the height of the stack, and a batter of about one inch in five from there to the bottom of the foundation.

In the illustrations are shown a photograph, plan, working drawings and details of a good example of smokestack construction and design. There were a number of problems of more than ordinary interest to work out in this particular case. In the first place, the stack, which is [illegible] feet high, was to be built on a footing of clay, in an exposed position swept by strong and cooling winds, and it was necessary to design a stack which would possess the maximum strength with the least possible weight, and at the same time of materials of such a character that but very little heat would be lost through the walls to the cooling winds. The problems were all satisfactorily solved by the simple expedient of using



HALF ELEVATION HALF SECTION

hollow tile instead of brick, as was formerly the practice, the foundation being built of concrete reinforced with steel.

The hollow tile were specially made for the purpose, were radial, 6 x 12 x 12 in size, hard burned, salt glazed, and laid with wire mesh in the joints, in cement mortar one to two. The finished stack is shown in Fig. 1, resting on its octagonal base, and extending to a height which makes a telegraph pole look like a toothpick. Owing to the numerous air cells formed in the walls of the stack by the countless dividing partitions of the hollow tile, there is no perceptible heat loss from the stack. This conservation of heat increases the draft of the chimney, so that the capacity is far beyond the ordinary rated capacity of a stack of this height and diameter. These air spaces further lessen the weight of the stack by many long tons, which in turn reduced the liability to lean or settle, over a stack of ordinary weight. At the same time the strength of the structure is increased by the less number of joints, and the radial shape of the blocks which makes them fit and interlock together. The cost of the stack was not considered, for efficiency and stability were the main requisites. Incidentally, though, the cost of the stack was much less than would be a like chimney built of bricks, and there was a further saving in time, the entire stack above the ground level having been built in about seven weeks.

RIVER IMPROVEMENT BY REGULATION AND DREDGING.*

By Major Wm. W. Harts.

In undertaking any river improvement for the benefit of navigation many considerations necessarily enter into the determination of the methods to be followed. It sometimes occurs that the solution is so obvious as to be self-determining, as at the Cascades of the Columbia River, where the advantages of a short lateral canal across a convex bank were so plain as to practically exclude other methods from consideration, but in the usual case there is a choice among several methods and usually considerable study is required to select the most suitable. This selection often depends more on the character of the river than it does on the nature of the use to which the work will be put.

For example, at Rock Island Rapids in the Mississippi River, where the channel has been successfully used for many years as the result of open river regulation, it was at first thought that a lateral canal would be necessary and such an improvement was proposed, even for the depth of 4½ ft. then needed. But a fuller study of the problem showed that the character of the river was such that the needs of navigation, as then existing, could be adequately met in an artificial open waterway supplemented by dikes and other contraction works.

The influences affecting the choice of a method of river improvement are changing, being constantly modified by later experience and by newer and better mechanical appliances. From present tendencies there seems small doubt but that in many instances lateral canals would probably no longer be so freely chosen at the present day as formerly, but that some type of canalization would be adopted instead if the project were up for determination anew.

The reasons which may incline the engineer to the selection of any particular type of improvement may be analyzed with advantage. The marked advance in recent years in the efficiency of machinery for excavation is one of these reasons which has more or less changed the economy of channel building and has had its effect on the choice of methods to be followed. Many harbor channels that originally could not be deepened owing to the high cost of effective improvement are now being dredged to depths suitable for deeper draft vessels. In New York harbor the Ambrose Channel, seven miles long, 2,000 ft. wide, and 40 ft. deep, is being dredged with sea-going hydraulic suction machines at the surprisingly low total cost of 5.4 to 5.7 cts. per cubic yard. (Professional Memoirs, Engineer Bureau, U.S. Army, January-March, 1909, pp. 61-62). Some years ago it was believed by many engineers that an effective entrance channel to this harbor could only be secured permanently by the adoption of protecting jetties of rip rap. The high cost of such work and its physical difficulties deterred engineers from undertaking it for a long time, and only within recent years has the construction of the entrance channel been considered economically possible, mainly through the greater perfection of dredging machinery.

This same tendency is felt to a certain degree on our rivers, and our ideas of improvement are likewise undergoing some readjustment, both as to practicability and as to choice of methods. Although this choice is often not as free as might be liked, since local conditions sometimes place narrow limits upon it, still, whenever one of several plans is to be selected for adoption the changing circumstances must be borne in mind.

For example, soft digging with a dipper dredge was done on the lower Tennessee River in 1910 for 3.6 cts. per yd., place measure, including all current field expenses, but excluding extensive repairs, plant cost and overhead charges. At Muscle Shoals Canal a record of 19 years shows that sediment has been removed from the canal at the same average cost, with a ladder of continuous bucket dredge. Including all charges the cost has been 5.16 cts. per yard at the latter place. In excavating through rock ledges exceptionally reasonable work has been done at Allens Bar, near Hobbs Island, where the entire cost, including blasting, dredging, loading on barges and dumping in dikes amounted to only 28.1 cts. per yard, including all current field expenses. These low prices are undoubtedly largely due to careful management, but improved machinery is nevertheless the important factor.

Before discussing the methods of river improvement, it may be desirable to enumerate the various classes of work used. The four principal divisions of river improvement methods are as follows:

(1) Contraction, including the use of spurs, sills, training walls and bank protection.

(2) Excavation, including dredging.

(3) Canalization, including locks and dams; and

(4) Lateral canals.

These methods are all well recognized and are in extensive practical use to-day. To these is sometimes added a fifth—reservoirs.

Engineers are ordinarily largely guided by their pre-preferences for certain classes of work, usually those met with in their own experience, and are often inclined to look with some disfavor on methods with which they are less familiar. But it would undoubtedly be best to recognize at once the good points of each tried method and combinations of two or more of them whenever found by experience to be advantageous. Untried theories and purely experimental modes of improvement will usually not receive extensive application at the hands of practical men.

On one point, however, most engineers will doubtless be agreed, i.e., that the navigable part of the river must be studied as a unit rather than piecemeal, and work must be done with some definite co-ordination so that a logical, systematic and connected improvement will result.

---

*Abstract of paper delivered before International Congress on Navigation.

No two rivers are just alike in slope, discharge, character of bed and banks, nature and size of drainage basin, or kind and amount of sediment carried, but in general it is observed that they are alike in some particulars; that they all have a more or less winding course with a constantly varying hydraulic radius, and consist of a succession of pools where depths are greater than the average, separated by bars where depths are less than the average. The fact is now no longer overlooked that these bars are like submerged weirs and have a decided effect on the elevation of the water surface. The danger of the early methods of improving the Rhone by deepening shoals separately, and cutting through bars independently of their relationship to the remainder of the river, has been repeatedly dwelt on by engineers. Unless contracted artificially, this invariably facilitates the outflow of the water of the pool above the site of the work, with a consequent lowering of the surface, and often causes an ultimate decrease instead of an increase of depths. On the Rhone at La Mulatiere the level of the low water surface was reduced to 4.66 ft. in 17 years by a deepening of the channels on the shoals below.

It seems plain that each separate work in a river should bear a similar relationship to the others as do the links of a chain. This need not prevent the gradual application of the methods selected, but would require that each work should form a part of a definite, comprehensive scheme.

The use of contraction works seems more particularly adapted to the portions of rivers where ample discharge, considerable width, small slope and gentle flow are met with. The Rhine below Strassburg, the Elbe from its entrance into Germany, the Niemen through Prussia, the Rhone below Lyons, are foreign examples of rivers that have been improved by these means. In this country the Mississippi above the mouth of the Missouri is an excellent example of this class of work, and instances of its successful application are found in the Columbia, Missouri and Tennessee Rivers, and on the French Broad and Hiawassee, tributaries of the Tennessee.

The amount of depth attainable by this method is ordinarily very limited. If the contraction is overdone, in rivers with movable beds an excess of scour may result, accompanied by a lowering of the water surface and perhaps a flattening of the slope in the lower reaches; or, if the beds are formed of resisting material, an excess of velocity may be [illegible]

It is an elementary principle that movable river beds must ordinarily be protected wherever contraction works are used, for otherwise the effect is sure to be largely local and the material scoured out by the currents is likely to be deposited elsewhere, frequently on other bars where depths were ample before. The protection of the banks in such cases is [illegible]

[illegible]

The navigability of unfinished rivers yet in a state of erosion can be improved with permanent results only by canalization.

(2) The most that can be accomplished by regulation is the desired adjustment of the slope of the low water line, and this only on reaches of uniform regimen and uniform characteristics.

(3) The feasible adjustment of the slope to be accomplished when the conditions are most favorable can only be established and brought about by constructive measures after the formation of that part of the channel which rises above low water is completed; after the conditions of the bed have adapted themselves to the change of energy caused by the formation of the mean and high water bed; in other words, after the erosion caused by this formation has come to rest.

(4) To secure the establishment and permanent preservation of the adjustment of slope, the irregularities of the bed in the longitudinal and transverse profiles are to be adjusted after reinforcing the low water shore, and the bed is to be strengthened where attacked by the water on account of the ground plan of the channel. Restriction of width alone will not bring about that degree of navigability which may be attained.

He also states that the depth attainable is expressed in the formula $d = \left(\frac{Q}{wk\sqrt{i}}\right)^{\frac{2}{3}}$ in which d is the depth; Q, the measured discharge; w, normal low water width; i, the adjusted slope, and k a constant corresponding to the constant of Chezy's formula. (Trans. Am. Soc. C. E., Vol, xxix, p. 220.)

If these views seem rather extreme as far as they bear on "unfinished" streams, the assumption that the gain is measured by the practicable amount of adjustment of the low water slope is open to much less question.

Dredging as an exclusive method of original improvement is seldom practised on interior rivers of the United States, except where the banks are comparatively low and unstable, the flow very gentle, and the discharge large. Navigable depths of 9 ft. in the Mississippi River below the mouth of the Ohio are now being supplemented by bank protection, the design being ultimately to protect the banks from caving by the use of brush mats and a rip-rap stone, and thus finally limit the bankfull channels to a predetermined width in order to accelerate the carrying velocity and insure regularity of regimen. This will also aid in maintaining depths and, perhaps, finally render much of the dredging unnecessary. Ten suction dredges of great capacity are employed in this work. It has been estimated from the surveys of 1908 that there were 749 miles of caving bank along the length of 790 miles of river between Cairo and the Red River, almost equivalent to one entire bank, and observations in 1892 indicated that 100,000 cu. yds. per mile fell into the river annually between Cairo and Donaldsville, La. It seems plain that until the banks can be protected nothing permanent or satisfactory can be expected. A recent plan for increasing this 9-ft. depth to 14 ft. proposes regulation of the low water slope by the addition of transverse sills combined with a revetment of the banks. Above the mouth of the Ohio and up to the mouth of the Missouri 8 ft. depths at low water are maintained by dredging, supplemented by the use of permeable dikes to restrict the river width at the bankfull stage [illegible] ft. These permeable dikes encourage the deposit of silt and the growth of new banks.

[illegible]

locks, and especially if funds are not sufficient for any other more radical improvement, resort is usually had to this kind of work. After a general scheme has been adopted work can be carried on at the difficult places first and in this way the most urgent needs of navigation met in order of importance.

Contraction works leave the greater part of the river open for boats, thus avoiding the delays at locks, are generally moderate in cost, can be changed if not entirely successful upon the first trial, may be applied gradually, do not flood the banks nor interfere much with high water flow, and ordinarily indicate the channel to pilots at low water. On the other hand, they require careful study for correct location, are not invariably successful, require considerable maintenance, and are usually limited in effect to a very few feet. They are not adapted to rivers of small discharge and steep slope.

Following European practice, the efforts to obtain 6 ft. navigation on the Ohio River above Cincinnati were directed during the early '80s toward improvement by dikes and training walls, of which many were built at the various shoals. In plan they left the bank in a long curve and followed down stream parallel to the channel, contracting the waterway without protecting the river bed. They were built to a height of 4 ft. above low water and their completion caused a disturbance in the equilibrium therefore existing and was usually followed by a local increase of depths, sometimes at the expense of decreased depths on bars lower down stream where the dislodged material was occasionally brought to rest. This method was only partly successful in the upper portions where the low water discharge was small and shoals frequent. When the 6-ft. project was abandoned and the 9-ft. project adopted for this river, the more radical method of locks and movable dams was selected and the use of training walls abandoned as insufficient.

Dredging in rivers, on the other hand, is immediate in its effect, the expenditure is applied directly to the seat of the trouble, and it is suitable for any type of stream. Dredged channels are usually not difficult to plan and their excavation is seldom accompanied by special engineering difficulties. When well located they are often fairly permanent. If the shoal is caused by a deposit of sediment it will sometimes reform, unless prevented by contraction works so designed as to remove the causes of the original deposit. On the Mississippi redredging each year is still necessary on some shoals, but in hard river beds, elsewhere the channels are often reasonably permanent. It is frequently the practice to use the excavated material in constructing dikes or training walls for a compensating contraction of the river in the neighborhood of the dredged cuts wherever the material is suitable, as is done on the lower Tennessee with good results.

If either dredging or contraction should be followed in river improvement to the exclusion of the other a considerable advantage would be lost, for it is by the combination of these two methods that the best open channels have been obtained in river work.

Regulation by spurs, sills and training walls, supplemented by dredging, merges without any sharp dividing line into dredging supplemented by contraction works, and the predominance of one method over the other will depend invariably on the character of the stream and the results to be achieved.

As a type of work where the contraction feature is the more predominant, the upper Tennessee is a fair example. There the present project is to obtain a 3-ft. depth at low water by open channel work. The methods followed to-day represent the outcome of many years' experience with dikes, bank protection, spurs and channel excavation and will be briefly described. The river has a normal width of about 600 ft., a discharge of about 2,500 second feet at low water, and 395,000 second feet at extreme high water. The bottom on nearly all shoals is either rock or hard gravel overlying rock at varying depths. The variation in bed and banks is so small from year to year that it may be justly described as of "fixed regimen."

The preliminary step is always a careful detailed survey showing the depths, nature of the bottom, low-water slope, and velocities at various places. A study of the physics of the locality is made and the action of the currents at varying stages observed.

The main steps in the work are then as follows:

First, the secondary channels back of islands are usually closed and the best location for the navigation channel selected. This location is almost invariably along one bank, the reasons for which are numerous, the following being the principal ones. It is more easily navigated, especially at night, more easily found by pilots, and more easily maintained, as it usually follows the convex bank where the tendency to re-fill is least. It is cheaper to construct, as the bank can be protected at less cost than a dike can be built; quicker, as the first cut of the dredge can be placed on the bank without using scows or barges for removing the excavated material; and better, as the channel can be straightened if needed and the minor irregularities in the bank corrected. Furthermore, spurs or training walls on both banks on opposite sides to contract the channel have been found difficult to navigate at intermediate stages of the river and often dangerous from the "draw" over them when submerged.

Second, the normal profile low-water width is calculated by the usual formulas involving the width, depth and character of bed, the discharge and slope of the river, and when obtained, is checked with actual conditions in normal reaches nearby. Formulas are never entirely reliable as no mathematical expression is equally applicable to the many varying cases met with, but they serve as a guide and when compared with the natural conditions are often useful.

Third, a combined system of bank protection, spurs and training walls, and sometimes sills when needed, are applied, so arranged as to hold up the water surface after the excavation is made, and so designed as to smooth out the inequalities in the low-water slope and distribute the fall over a longer stretch of river than before in order to reduce the extreme velocities.

Fourth, the bottom is drilled and blasted, if necessary, the material is dredged out and placed in the dikes, and after completion the shoal is re-surveyed to see whether further changes are necessary in adapting theory to the problem. Gages are placed before commencement along the site of the shoals, at the head and foot, and about a half mile above and a similar distance below, to ascertain the effect of the dikes. These gages are read daily. When finished, a survey of the work is made and the new slopes and velocities plotted. It sometimes happens that this survey will indicate that some dikes must be prolonged, or the channel narrowed, or perhaps a dike lowered in height to obtain the best results.

A very satisfactory example of this kind of work on the Tennessee River is at Little River Shoals. The maximum slope was originally 0.5 ft. per mile at low water and is now about 5.3 ft. The low water discharge is about 2,500 cu. ft. per second and high water discharge 395,000 cu. ft. per second. The maximum velocity at low water was over 8 ft. per second, and this has been so reduced that "warping" in passing up is no longer necessary.

On this work the rock excavation cost $1.92 per cu. yd., made up of drilling and blasting at $1 [illegible] per cu. yd. and rock dredging at $0.21 per cu. yd. Gravel cost $0.10 per cu. yd. to excavate. The dikes cost $1.74 per lin. ft, or $2.55 per cu. yd. Dikes were largely constructed of material excavated from the channel.

On the other hand, there are examples of a different kind of combination of dredging and contraction in the lower reach of the Tennessee River where the excavation is the predominating part and the contracting works are mainly for the purpose of compensating for the increased cross sectional area of the river, due to the newly dredged channel. In this section the distance from Riverton to Paducah is 266 miles; the total fall at low water 77 ft., or an average of 0.34 ft. per mile at low water. The low water discharge is about 10,000 cu. ft. per second. The project provides for a channel 150 ft. wide and 5 ft. deep at low water over all the shoals. Dredging has been very successful on this section, and the dredged cuts remain open in most cases without any later work. This is believed to be largely due to the contraction of the river opposite each cut by dikes which are composed of the dredged gravel and so placed as to hold the water surface without material change. It has not been found practicable to raise this surface to any important degree by these dikes, but their apparent usefulness in preventing any decrease of depth warrants some additional cost for construction.

[illegible]

The various combinations of these two kinds of work, viz., contraction and dredging, represent one important method of improvement that has been extensively applied in cases where the river characteristics and required navigable depths permit, but their usefulness is by no means universal.

Canalization must be resorted to whenever the discharge of the stream is too small for open river work, or the slope [illegible] the depths permissible thereby insufficient, and will usually be considered when it has been found that the simpler and cheaper means before described are not applicable. Canalization costs more per mile, its maintenance is higher, and its delays to down-stream traffic are usually greater. But its results are positive and immediate; it renders up-stream navigation easier than before and affords greater safety to vessels than the other methods. Where [illegible] regulation and canalization is given in Tables I, II, and III

[illegible] capitalized maintenance charges, the disparity will really be [illegible]

But with the lateral canals the case is somewhat different. By means of a lateral canal with one or more locks the obstruction in the river at any particular locality may often be obviated, and some years ago this method of river improvement was widely advocated. Brindley, an English canal engineer, is said to have stated that "rivers were created for the purpose of feeding canals," and apparently acted on this belief.

Lateral canals are expensive to build and maintain, frequently cause undue delay to vessels in passing each other or in grounding, are easily blockaded through accident, and require constant expensive attention. They form pools of still water where sediment collects, requiring constant dredging. At Des Moines Canal on the Mississippi River there had been removed from the canal between 1878 and 1906, 2,181,743 cu. yds. of sediment, a volume larger than the original excavation.

At Cascades Canal, Columbia River, periodical dredging is necessary to keep the upper and lower entrances clear, and at the Muscle Shoals Canal, Tennessee River, one dredge is kept constantly busy through a large part of the year removing sediment brought in by the drainage of side creeks and the inflow at the head during times when the river carries silt. Since opening the canal (1892) over 1,300,000 cu. yds. have been removed.

The costs of various lateral canals in this country and abroad are given in Table IV.

The high first cost and later charges for maintenance make this method of improvement such a costly one that it would probably to-day be often supplanted by canalization. High speed cannot be allowed in canals owing to the wash caused along the banks, but in canalized rivers no such limiting condition exists. Colonel Wm. E. Merrill, Corps of Engineers, an eminent river engineer, stated in 1887, while commenting on the Muskingum River, as follows:

"The greatest obstruction to successful navigation on the Muskingum is caused by the lateral canals; they are expensive to keep up on account of the guard gates, the numerous draw-bridges, and the necessity of periodical dredging. Even when in perfect condition they must be navigated slowly, and it is with difficulty that boats can pass each other."

At Colbert Shoals on the Tennessee River the lateral canal now nearly completed provides a lift of 26 feet, which is overcome by a single lock. Before undertaking its construction it was several times proposed to build one or more dams across the river and canalize these shoals, but the possible use of the river at high stages, when fixed dams might interfere with the boats, decided the engineers to adhere to their first selection of a lateral canal.

At the Des Moines Canal a project is now on foot to build a power dam in the Mississippi which will "drown out" the present canal. Locks will be used in passing vessels from one pool to the other but the old canal will have to be abandoned should this plan be put into execution.

Similar plans for the Muscle Shoals Canal on the Tennessee River have been proposed, but no satisfactory agreement has ever been made between the power corporation having the work in view and the government as to the proportionate share each should pay toward the project. As a consequence, nothing has yet been accomplished.

[illegible] that the con[illegible] the selection of this type of work are chang[illegible] would probably not be selected in some of these instances.

[illegible] canalization is easily first among methods and is now being used more than all the others combined. But little new work of regulation is being under[illegible] new lateral canals are now being commenced in this country. Except the Rhone and the Loire, nearly all the improved rivers of France are canalized, about 970 miles in all; and in Germany, where there are nearly five times as many miles of open as canalized rivers and regulation finds its warmest advocates, but little new regulation work of importance has been done since 1875. In Belgium there are four times as many miles of canalized rivers as open rivers. (Royal Commission, Waterways and Canals—Lindley.)

A fair conclusion is that the present tendency is toward the selection of canalization whenever a new system is to be chosen, particularly if the examination of the natural and economic conditions shows regulation to be inapplicable. It also seems that lateral canals are not now being regarded favorably unless the local conditions unequivocally indicate the necessity of their adoption.

The theory of the use of reservoirs as an exclusive mode of improving rivers for navigation is an old one practically abandoned now in this country by river engineers but revived from time to time by its advocates and sometimes made the subject of an academic discussion of considerable seriousness. At first glance the theory is very engaging, but experience in its application has been in the main unsatisfactory and its applicability depends on many assumptions which are themselves of doubtful tenability.

*Over 10.5 feet up to Paris.

The possibility of conserving the high water flow of rivers, thus reducing injurious floods and later using the stored supply during the low stages for the benefit of navigation, is fascinating alike to layman and theorist, and offers a wide field for speculation. But the attempt at practical application usually introduces virtually insurmountable difficulties.

The theory takes it for granted that sites for reservoirs, ample in number and capacity, can be obtained without greater injury to railroads, factories, towns and valuable private possessions than the benefits to be obtained for the public; that enough high dams can be safely built at reasonable cost free from danger of a breach operated intelligently and efficiently in order to create the necessary storage space for regulating the discharge. It assumes further that these reservoirs are not likely to be soon filled with silt but are practically of permanent usefulness. It assumes that increased discharge in the rivers means increased depths, and that precipitation may be foretold with sufficient accuracy to permit successful regulation. All of these assumptions are more or less debatable and some of them are plainly of doubtful reliability.

The reservoir theory has never been practically applied on a large scale as an aid to navigation except in two cases, and the results there have not been encouraging. It was early adopted on the headquarters of the Msta and Volga Rivers in Russia, where its use was the outgrowth of very favorable natural conditions. These rivers, flowing in opposite directions, take their source in a lake and swamp region at an elevation of 665 feet above sea level where land was cheap and unfit for agriculture. Here the construction of low, cheap dams was an easy task, resulting in increasing the reservoir effect very greatly without the necessity of obtaining new storage sites or going to much expense for dams and regulating works. A natural reservoir system was in fact already in operation, needing only a little artificial regulation. The capacity of this system is 35,000 cubic feet with dams only 17.5 feet high. (Reservoir sites in Wyoming and Colorado.—Chittenden.) It is usually considered a fairly efficient work in lengthening the season of navigability of the two streams.

*Annual Report Chief of Engineers, U S A, 1910.
¹Repairs only. ²Operating cost only. ³Includes operation. ⁴Office records. ⁵In West Virginia. ⁶About.

The same favorable natural conditions were found on the upper Mississippi River and similar reservoirs were built by the government for improving navigation in the '70's. By constructing low dams across the outlet of an extensive lake area, a storage of 93,400 million cubic feet was accomplished at a total cost of only $678,300. (Reservoir Sites in Wyoming and Colorado.—Chittenden.)

Although the Russian reservoir system was in a measure successful, the effect of these reservoirs upon the Mississippi River at St. Paul, 357 miles below the dams was slight, being from 12 to 14 inches on an average, and 51 miles further down all trace of it disappeared altogether. But the dams were so beneficial for the production of power that when their abandonment by the government was being considered some years later such a course was vigorously opposed by the milling companies and other similar interests benefited, although they contributed practically nothing toward the expense of the work.

The system has never been extended in the United States although often studied. The slight assistance to navigation and the high comparative cost of construction and maintenance were reasons given for not applying this method of improvement to the St. Croix, Chippewa and Wisconsin Rivers, which were examined several times a few years later by engineers' boards. (Annual Report, Chief of Engineers, 1887, page 1692.)

It is stated that early in the last century the plan was adopted to some extent in France for the control of floods, and in 1856, after a flood of unusual destructiveness, it was thoroughly studied, more particularly with reference to its applicability to the Rhone, Seine, Garonne and Loire. As a result of this investigation it was decided not to construct the reservoirs proposed for these streams owing to the "uncertainty and doubtful efficacy of their action." In 1881 this system was definitely abandoned by the Corps de Ponts et Chaussées and its use for the control of rivers condemned in France. (Annales des Ponts et Chaussées, 6 sem., vol ii, [illegible])

The plan was proposed for the improvement of the Ohio in 1873 but was not favorably considered after careful investigation. The board in whose hands this investigation was placed stated "The first of these plans (viz., storage reservoirs) the board deems impracticable on account of the difficulty, if not impossibility, of finding locations for the necessary reservoirs, the immense cost of the system, its interference with navigation of the tributaries on which the dams are located, its injury to agricultural, mining, and railroad interests in the valleys of these rivers, the difficulties of regulating the supply from the reservoirs, and the terrible effects that could be caused by accidents." (Annual Report, Chief of Engineers, 1873, p. 541.)

[illegible]	[illegible]	2	[illegible]	[illegible]	1,910,162	[illegible]	[illegible]

In 1909 the plan was again suggested to a board of engineers having in their charge the project for the improvement of the Mississippi River, and again the plan was abandoned for lack of sufficient reservoir sites, high cost, and uncertainty of action. The board stated in its report that "In order to use this reservoir system for the benefit of the improvement of the river below St. Louis it would be necessary to commence the discharge at the reservoirs at least two months before it was needed at St. Louis, and a still greater interim would be necessary for the benefit of the improvement of the river below Cairo. Experience does not justify such long forecasts, and the service of the reservoirs would necessarily have to be based on general annual averages, an unreliable and unsatisfactory basis." The board also stated that [illegible] with the expense." ([illegible], p. [illegible])

[illegible] the Ohio River was being considered by a board of river engineers, [illegible] The estimated cost of the adopted plan for 6 ft depths by locks and movable dams is about 63¾ million dollars.

The general impression among river engineers in America seems to be that storage dams for the benefit of navigation alone will never be warranted. Similar dams have been constructed in many places for industrial purposes, such as power development and irrigation; but these purposes are not always in harmony with channel improvement, and the incidental benefits likely to be received on navigable streams from dams built for several combined purposes cannot always be determined in advance nor their value accurately estimated.

If an added flow at low water be furnished from such dams, the valuable scouring effect of low water may not be obtained without a supplemental series of contraction works at further additional cost, and the increased discharge may not mean increased depths on many sediment-bearing streams. For example, on the Mississippi, where much material is rolled along the bottom, bars often rise and fall with the gage heights, the low water being largely relied on to restore the channels in such cases.

Then, too, the location of the dams on the tributaries would usually be such as to intercept much of the flow of silt in suspension in the portion of the stream where the scour is greatest. In no other way could the water be clarified. This clarification is an assumed advantage of the reservoir system that has often been mentioned.

There is no known way of safety and easily removing silt from behind storage dams, more particularly if it is expected to do so without much injury to the river channels below. A constant diminution in storage capacity would be one of the inevitable results of the system, or an injurious deposit in the lower channels it is intended to benefit.

Notwithstanding these disadvantages, there may occur special cases where some incidental benefit may be derived, but experience seems to point out that such benefit will hardly ever be sufficient to very strongly influence the location of any storage dams or warrant any considerable portion of the cost being borne by the navigation interests.

As a summary of this discussion, the following conclusions are briefly stated:

1. Regulation in some suitable combination with channel excavation should always be first studied as a method of river improvement and adopted in all cases where economically applicable. It will be oftenest used wherever the funds available are small in amount, the increase of depth needed not great, the river flow comparatively large, the banks low and the width of the river considerable, velocities low and regimen more or less fixed.

2. Canalization with movable or fixed dams will be adopted wherever regulation with channel excavation is insufficient or unsuitable. It will usually be applied where the slope is steep, discharge small, and depths obtainable by regulation insufficient.

3. Lateral canals should never be selected for use unless imperatively demanded by the local conditions.

4. Reservoirs are too uncertain, too unsafe and too expensive for exclusive use in river improvement. They will seldom be relied on, except in special cases in connection with other enterprises where their use for industrial purposes warrants the cost and the water flow can be sufficiently controlled to operate beneficially on the channels.

◆

Messrs. [illegible] V. Kendall and Leonard Martin, F.R.I.B.A., architects, of London, England, have won the award in the competition conducted by the Toronto Housing Company for plans of houses for the development of the company's land in the east end of Toronto.

LARGE SUBMERGED SEWER OUTLET.

The city of Rochester, N.Y., is installing a sewage disposal system, some of the work of which is very interesting, particularly that of laying the effluent pipe in Lake Ontario. In a recent issue of the Municipal Journal, of New York, Mr. John F. Skinner, principal assistant to the city engineer of Rochester, describes the method of laying this pipe. The following abstract is made from the article:

The city up to the present time, has been drained by a combined system into the Genesee River through eight main outlet sewers, which serve territories having areas varying from 187 acres to over 5,000 acres. An interceptor is being constructed to receive the dry weather flow and two and one-half additional volumes of storm water from these outlets, which sewage and storm water will be conducted to disposal works near the lake, and the effluent discharged at a point 7,065 feet from shore in about 50 feet of water.

The effluent conduit will be a 66-inch lock-bar pipe, made up of ½-inch steel plates dipped in "Pioneer Mineral Pipe Coating." Proposals for this portion of the work were received March 13, 1912, and on the following day the contract was awarded to the T. A. Gillespie Co. A summary of the bids is given on the next page.

It will be noted that tenders were also invited for "Ingot Iron" from "Cast-Iron" pipe. It was not thought, however, that the existing conditions warranted the greater expense for material other than steel. The high cost of the cast-iron pipe is, in a measure, due to the requirement which specified that it be laid on pile bents.

Borings made in the lake bottom indicate fine sand and some clay with but little gravel.

The crib, which is 46 feet square and 24 feet high, is constructed of 170,000 board feet of 12 x 12-inch hemlock timber. It contains a steel special to which is bolted the last length of the pipe. The special has a 6-inch outlet in line with the pipe and two 38-inch outlets, one on each side. These three openings are provided with flanges so that they may be extended, if necessary, and the side openings are closed with steel covers.

The crib has pockets loaded with 1,075 cubic yards of stone. It was constructed at a dock two miles up the river from its mouth, and was towed to its site, two miles east of the river's mouth, where it was sunk, guided by piles driven on two sides of its position.

The lake bed was dredged so that the bottom of the crib is 3 feet below lake bottom, the mouth of the discharge pipe is 10 feet below lake bottom, and the top of the crib will be 26 feet below low water.

The contractor's plant consists of a 12-inch hydraulic dredge with 90-foot ladder; a pile driver scow 32 feet 6 inches x 80 feet; two derrick boats, the smaller one 21 x 50 feet, and the larger 34 feet 6 inches x 95 feet; two tugs, and a diver's boat with two complete equipments.

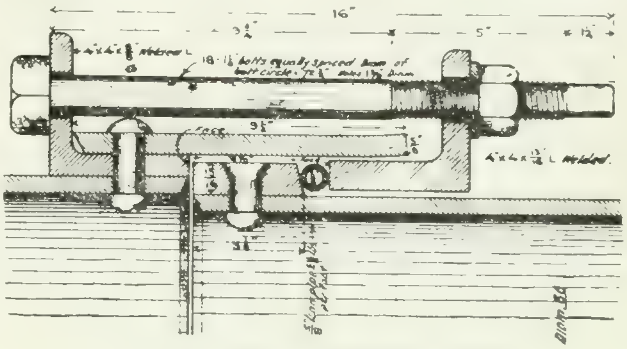

Fig. 1.—Detail of Submarine Joint.

The pipe leaves the crib a little above lake bottom, curves downward and then horizontally so that the remainder of the pipe can be laid in a trench and backfilled about 2½ feet deep. The curved pipe will be covered with a mound of sand, and 400 cu. yds. of rip-rap will surround the crib.

The plan is to dredge a short portion of the trench, drive four piles at each end of a pipe length, lower a section of pipe into position and while it is supported from the pile clusters make the joint and backfill the trench before moving to the next length.

The submarine joint used consists of a socket on one pipe into which the spigot end of another pipe is inserted. A gasket or ring of 1-inch heavy lead pipe is forced into the base of the socket by a follower which is drawn up by bolts manipulated by a diver. The city also has a diver who inspects the work.

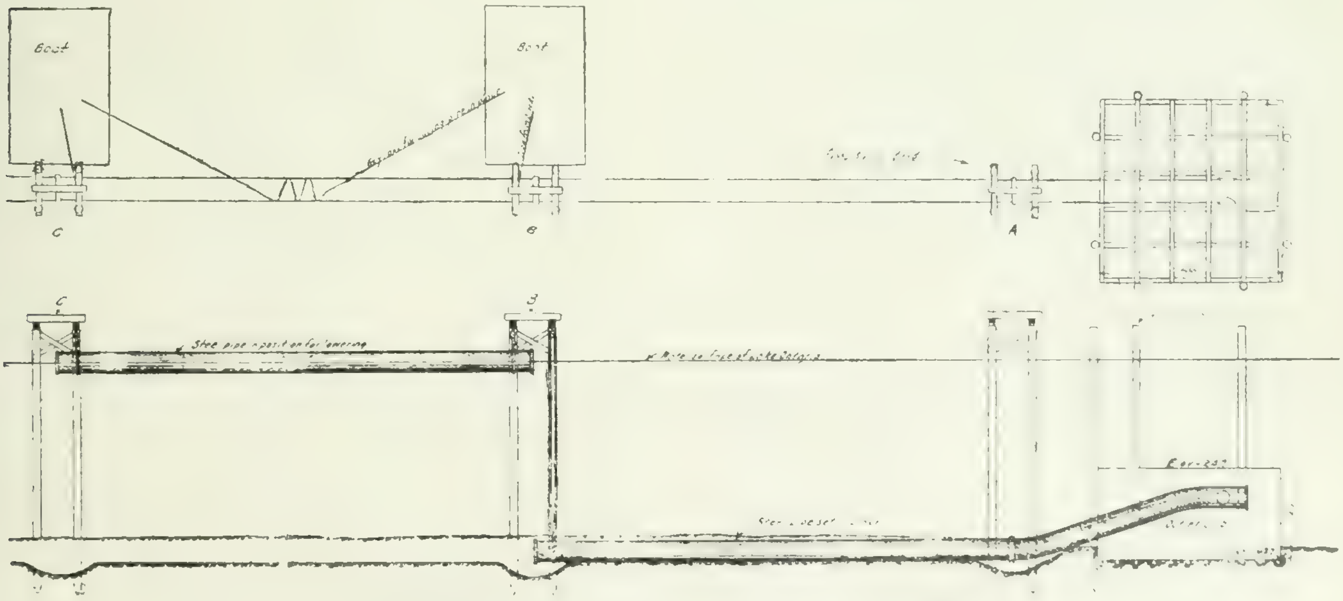

Fig. 2.—Proposed Method of Laying Outlet Pipe from Crib to Shore.

The pipe, which is received in 30-foot tapered sections, is riveted into 120 and 150-foot lengths. The 150-foot lengths will be laid in the trench from the disposal plant to the shore and in shallow water, while the 120-foot lengths will be laid in the deeper water. The crib was satisfactorily sunk on Friday, July 26, reaching the bottom at 6 P.M.

The accompanying sketch shows the relative position of the crib and derrick boats and the method of mooring. By manipulating the mooring lines, the crib was held snugly against the guide piles during the lowering. But little more stone was put into the crip than was required to sink it; the remainder of the pockets will be filled later.

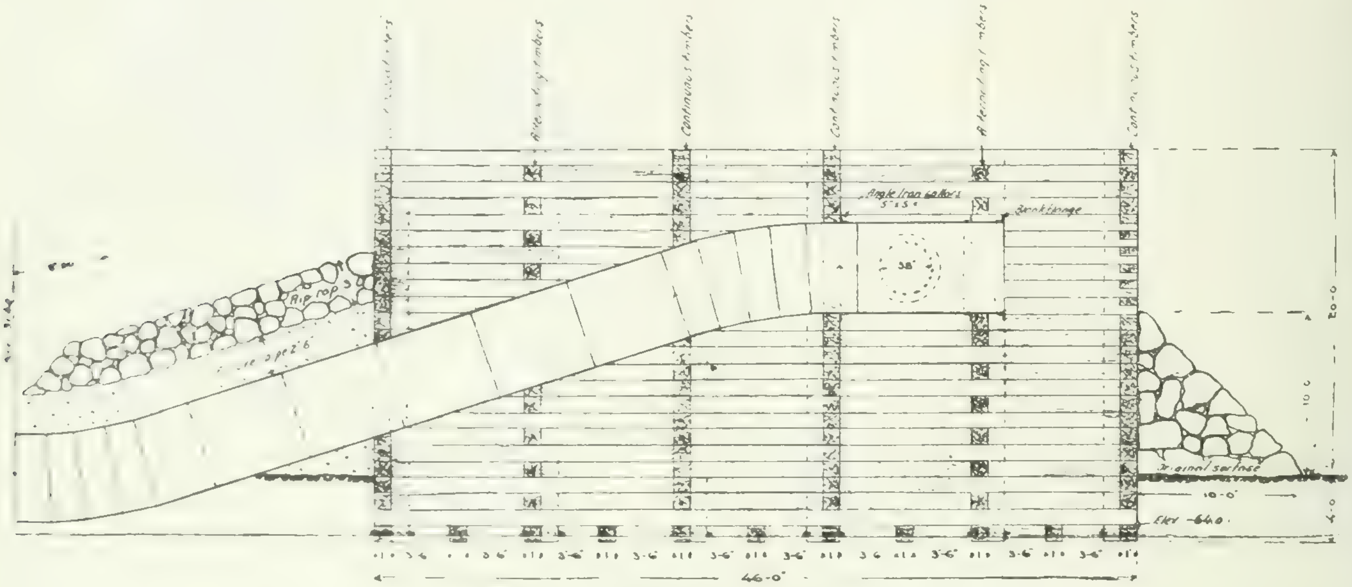

Fig. 3.—Section Through Centre of Crib and Pipe.

The pipe will be laid from the crib toward the shore, where a slip joint will be made with the shore pipe.

The work is in charge of Frank Wilcox, M.Am.Soc.C.E., engineer, and E. S. Williamson, superintendent for the contractor, and is being directed by C. Arthur Poole, Assoc. M. Am. Soc. C.E., general assistant on sewage disposal for Edwin A. Fisher, M. Am. Soc. C.E., city engineer.

In addition to the above, the following details may be of interest:

The [illegible] outlet pipe is to be [illegible] in lengths [illegible]

The joint at the shore end of the outlet pipe is a slip joint, consisting of two cylindrical sections of ½-inch pipe, one 66 inches inside diameter and 4 ft. 9 in. long, the other slightly greater than 67 inches inside diameter, so that the two may telescope one within the other. At the end of the outside section a ring of angle iron is fastened with its face flush with the end of the section and entirely surrounding the outside of the pipe, bolted to which and 2 inches from it is another ring of angle iron of similar diameter, so that the two give between them an annular space of 2 inches. In this space is placed a ring of 2-inch rubber, the diameter of the ring being 6 inches less than that of the outside of the smaller telescoping section. This will provide a water tight joint between the rubber ring and the latter section, and by screwing up the bolts connecting the two angle iron rings a water tight joint is made between the outer section and the rubber ring. This joint provides for a lateral movement of 36 inches to allow for expansion or contraction in the length of the pipe line.

The outlet crib is 46 ft. square on the outside and is divided into 25 pockets, which extend from the top to the floor at the bottom. The crib is constructed of 12 x 12 timber fastened together with [illegible]-inch by [illegible]-inch drift bolts and one-inch bolts with head and nut. A 12 x 12 post was placed at each corner, two posts on each side at the corners of the pocket on the middle of that side, four posts at the

[illegible]

corners of the central pocket, and four other posts on the diagonals between these latter and the corners of the crib. These pockets are 8 ft. square inside dimensions and the entire crib is 23 ft. high. Thirteen of the horizontal timbers are bolted to each vertical post. A drift bolt was used at each intersection of horizontal timbers. In walls of continuous timbers, butt joints were permitted, with a drift bolt in each timber. In the walls having alternate timbers, half-lap joints were required, giving a 12-inch lap, and fastened together with two 12 x 6 x 24-inch fish plates fastened with three one-inch bolts; the splices breaking joints at least 4 feet. It is provided that ultimately all the compartments be filled to the top with loose stone, excepting those through the centre of the crib (through which the outlet pipe passes), these being filled only to the bottom of the pipe; and excepting those at right angles to the outlet pipe and in line with the two T outlets at the end of the pipe, these compartments being filled up to the level of these outlets, at which level the compartments were floored over with 3-inch plank from the outlet pipe to the sides of the crib, thus providing a channel through the crib connecting the side outlets with the surrounding water. When finally in position, the crib is to be surrounded with rip-rap, as shown in the illustration.

◆

WINNIPEG AND ITS WATER SUPPLY.

For some time the municipal authorities and certain ratepayers have been facing a problem which they felt must be solved with all possible speed and expediency or the industrial future of this city would be marred. This problem was the same as has been faced, and will be faced, by many cities in Western Canada; that is the supplying of the citizens with a water supply that is beyond question as to its quantity and quality. To this end and for a conclusive movement in the matter the authorities engaged the services of Professor C. S. Slichter, of Madison, Wis., to prepare a report.

The chief available sources of supply are the Winnipeg River, the Poplar Springs, the Crystal Springs, artesian wells and Shoal Lake; the last named is the source recommended in the report, and is about ninety miles distant from the eastern extremities of the city as defined at present.

According to Professor Slichter, the water of this lake would require no treatment before being delivered to the taps of the consumers. No fear need be felt that the sanitary qualities of the water would be poor at any time in the future. The shores of the lake are hard rocks of the Laurentian series, entirely unfitted for agriculture, and the country thereabouts must remain in its present wild state indefinitely. There need be no fear of the growth of cities or towns upon the shore of Shoal Lake. The Lake of the Woods constitutes an enormous reservoir of clear, pure and soft water, situated 300 feet above the city of Winnipeg.

The well system of Winnipeg covers a north and south range of about five miles, and the amount of water intercepted is less than 2,000,000 gallons per day per mile. In several of the river valleys of the plains, similarly situated, it is possible to withdraw over 10,000,000 gallons per day from each mile of section. The mutual interference of the wells has been considerable. Well 5 has been especially active in cutting down the supply of wells 2, 3 and 4, but well 5 has, of course, greatly increased the yield of the group..

The above average yield of 2,000,000 gallons daily per mile can be materially increased by deepening existing wells 1 and 2, by the distribution of a more uniform draw-down or draft throughout the cross-section.

The amount of ground water pumped at Winnipeg in the past ten years is not large. The total pumped since the installation of the well system would cover a township of land with about two feet of water, an amount of water that the city of Winnipeg will require in a single year in the not distant future.

It must be borne in mind that a part, at least, of the water taken from the ground in the last ten years represents water that was merely stored there, and not flowing on. The static head has materially dropped. Some of the water used represents actual depletion, just as there is depletion when one draws upon a deposit of oil or of coal.

The group of springs known as Poplar and Crystal Springs seems to have a combined flow of between ten and fifteen million gallons per day. From measurements submitted by Col. Ruttan it seems that the flow is increased within less than a mile to 5,800,000 gallons per day. Prof. Slichter's own measurement of Poplar Springs, at the outlet to the same, was 1,190,000 gallons per day. The measurement made by J. F. Henson in August, 1910, at practically the same point, was only 894,000 gallons per day.

In spite of more or less discrepancy in the various gaugings, and notwithstanding the lack of sufficient number of weir readings, the natural available flow of the Springs is possibly more than 10,000,000, and probably less than 15,000,000 gallons per day.

There can be no question of the sanitary purity of the Spring water. It is amply protected from surface contamination by the impervious surface deposits. There need be no fear that any portion of the water naturally flowing from the Springs is bog water. The temperature of the bog just above the water plane on August 25th, 1912, was 51 degrees Fahrenheit. The temperature of the Spring water is about nine degrees lower.

A visit was made to the proposed intake at the Seven Portages of the Winnipeg River. The quality of the water at this point, it is assumed, was settled by the report of the commission of 1907. Rough tests were made of its turbidity and color by means of a white disk. The water, in the condition found on August 25th, 1912, would require the treatment recommended in the report of 1907. The suspended matter and color were both high on the date seen. In addition to the spores of water plants, algæ and minute particles common in nearly all river waters, there were numerous small bits of moss, etc., in suspension, which seemed to have been dislodged by the rapid current. The color and all of the suspended matter would be removed by the treatment proposed in the report of 1907, and the sanitary character of the water after proper treatment would be satisfactory.

The estimates of the cost of the supply from the Winnipeg River are printed on page 88 of the report of the commission of 1907. The proposed pipe line was to be 58.3 miles in length, about seven miles of which is in rock, and to consist of 35,000 feet of 45-inch pipe, 26,400 feet of 54-inch pipe, and 229,700 feet of 48-inch pipe. For a daily capacity of 23,000,000 gallons the estimates were:—

1—Land and right-of-way	$ [illegible]
2—Intake works	[illegible]
3—Pumping station at Winnipeg River	325,000
4—Pipe lines	1,737,000
5—Coagulating basins	65,000
6—Filters	250,000
7—Filtered water reservoir	270,000
8—Winnipeg pumping station	370,000
9—Keepers' houses	[illegible]
10—Telephone lines	[illegible]
11—Tramway	[illegible]
	$[illegible]
Add 15 per cent.	[illegible]
Total	$[illegible]

The present water supply of the city of Winnipeg from the well system is so highly undesirable and expensive on account of its high mineral content that it should be abandoned at the earliest possible date. The water is excessively hard and incrusting, and is corrosive and destructive to an unusual degree. The expense that this water now causes the citizens of Winnipeg by its destructive influences on plumbing, boilers, heating plants, etc., and increased cost of fuel, soap, compounds, and the destruction of woolens and other laundered articles, would well pay the interest on $15,000 to $20,000. As the city engineer has tersely remarked in his printed report: "The water in its natural condition is much too hard for general domestic and boiler use." The water is expensive to soften, and after treatment it is still hard water, and, more than that, still retains all of its corrosive qualities. The water is not only destructive of health; it is a handicap to and a serious drawback to the proper operation of many industries and a hindrance to the introduction of new industries. The following typical industries would be seriously handicapped by the present supply: Meat-packing industries, canning industries, woolen mills, starch and kindred potato product industries, any industry, of which there are many, that requires the use of live steam, or drying processes, or distillation, or kiln-dried material, or the application of heat for digesting or liquifying or combining a variety of commercial substances. There is no industry that would not be favorably affected by an abundance of pure, soft water, and to many it is an absolute essential.

It will be readily seen why the council are asked to abandon the present sources of supply and look toward Shoal Lake for the future.

Shoal Lake lies almost exactly 300 feet above the city of Winnipeg. It is a large, irregular body of water, of extreme dimensions 13 by 14 miles. The commission of 1907 proposed in their estimate, Number 9, page 95, 22.6 miles of 64-inch pipe, 27 miles of 54-inch pipe, 43.0 miles of 48-inch pipe, with intake laid in about 20 feet of water, extending about six miles through Indian Bay to an intake crib in Shoal Lake. The estimates submitted on page 95 of the report of 1907 give, for a daily capacity of 23,000,000 gallons:—

[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]
[illegible]	[illegible]

Total	[illegible]

[illegible] at the station, 22.6 miles from Shoal Lake. This plan, if [illegible]

[illegible]

[illegible]

ject, to provide for the construction of the first conduit. A like expenditure should be contemplated for construction of a second conduit later on.

3. That the construction of the first line be begun at the earliest possible moment, and that every effort be made to finish the line by July 1st, 1916.

3. That an additional storage reservoir of 18,000,000 to 20,000,000 gallons capacity be immediately constructed within the city of Winnipeg. Such reservoir was duly included in the estimates of the Shoal Lake project.

4. That additional 18-inch wells be drilled in continuation of the present system, in and near the city, to furnish additional water until the Shoal Lake project is in readiness. An 18-inch hole should be drilled at once, both in Wells 1 and 2, and Well 7 should be tunnelled in search of shattered or cavernous rock. A number (at least 15) of 18-inch wells, in addition to the number thirteen now being sunk, should be drilled at once, about one-quarter mile apart, in lines north, and also west of the present wells. Each satisfactory 18-inch well should be equipped with direct-driven, multiple stage, centrifugal, deep well pumps.

5. Before an intake pipe for Winnipeg water supply is finally laid out in Shoal Lake, observations, during the entire summer season, should be made by a competent person, in order to locate the best point of diversion.

◆

THE PORCUPINE POWER COMPANY PLANT.

At Sandy Falls, six miles north-west of the Hollinger Mine, or eight miles from Timmins Landing down the Mattagami River, the Porcupine Power Company has installed a hydro-electric power plant for the purpose of supplying power to the Porcupine District. The accompanying cut is taken from the last report of the Timiskaming and Northern Ontario Railway Commission. The installation consists of two pairs of 43 inch turbines, rates at 1,700 horse power with a 34 foot head, and two generators of 1,500 horse power each, 25 cycle, 3 phase, 12,500 volt, 214 r.p.m. Foundations for a [illegible] power have been prepared and [illegible] additions to the plant can be made whenever required. [illegible] light and power to the [illegible] of Porcupine and South Porcupine, and to the following [illegible] Hollinger, [illegible], [illegible] and Dome.

[illegible] in advance of the time that they are ready to utilize it.

THE GREAT LAKES AND TYPHOID.

The boundary waters between the United States and Canada are rapidly becoming polluted, as is evidenced by the typhoid death rate of some of the cities located on them. We are glad to note, therefore, that the International Joint Commission has been instructed by the governments of both countries to investigate the question of pollution of boundary water. The questions laid before the Commission are as follows:—

> "1. To what extent and by what causes and in what localities have the boundary waters between the United States and Canada been polluted so as to be injurious to the public health and unfit for domestic or other uses?
>
> "2. In what way or manner, whether by the construction and operation of suitable drainage canals or plants at convenient points or otherwise, is it possible and advisable to remedy or prevent the pollution of these waters, and by what means or arrangement can the proper construction or operation of remedial or preventive works, or a system or method of rendering these waters sanitary and suitable for domestic and other uses, be best secured and maintained in order to insure the adequate protection and development of all interests involved on both sides of the boundary, and to fulfil the obligations undertaken in Article IV. of the Waterways Treaty of January 11th, 1909, between the United States and Great Britain, in which it is agreed that the waters therein defined as boundary waters and waters flowing across the boundary shall not be polluted on either side to the injury of health or property on the other?"

The Secretaries of the International Joint Commission have, by the direction of Chairman Tawney in the United States and Chairman Casgrain in this country, sent requests to the mayors of all the cities along the international water boundary for data regarding their water supply and sewerage systems, with the expectation that much of this information will be ready to submit to the Commission when it meets in Ottawa the first Tuesday in October.

A great deal of valuable information, no doubt, will be received. The result of the investigation will be awaited with interest. One result, no doubt, will be the co-operation of the two countries in forcing cities and municipalities to purify their sewage before allowing it to be discharged into the Great Lakes.

◆

THE HUDSON BAY ROUTE.

Preliminary reports from the Hudson Bay survey parties on board the Government steamers which are investigating ice and navigation conditions in Hudson Bay and the Straits this summer in connection with the proposed Hudson Bay Railway are not very encouraging as to the safety and feasibility of the route, so it is reported. The ice conditions, especially in the Straits, have been found to be unusually bad, exposing vessels to both serious danger and delay. While the desire for another outlet for Western wheat and another ocean route to Europe, is natural, surveys and investigations prove that the Hudson Bay route is entirely impracticable. Navigation would be hazardous, and for only a short period of the year. Even the St. Lawrence route, with all its recent improvements, cannot obtain sufficiently low insurance rates. What rates could be obtained, then, on the Hudson Bay route?

Would it not be better for the Dominion government to concentrate its efforts upon the development of ports and routes which have already proved their merits? Montreal, for instance, cannot cope with the enormous business going that way. The present facilities there are not equal to the business offering, despite the energy and enterprise of the Harbor Commission. Montreal has every right to be considered one of, if not the leading of our national ports. If immediate steps are not taken to keep pace with the business, it will drift to foreign channels. The fact that many large grain boats were kept waiting there so long, that the owners were compelled to take their vessels off that route, is a serious matter, and but an indication of the more serious consequences which might easily follow. Our winter ports, too, should be improved materially.

Little has been done to make Vancouver the great ocean port it should, and must be, if it is to gain materially from the opening of the Panama Canal. Mr. Monk, the Minister of Public Works, was, unfortunately, correct when he stated that we are a quarter of a century behind in our port development. This is a matter for earnest consideration. The Hudson Bay scheme should be abandoned by the Government, with a frank statement that the proposed route is too hazardous and quite impracticable.

◆

THE MEDICAL HEALTH OFFICER AND THE ENGINEER.

The duties of the medical health officer and his general relationship to the public are too well known to warrant comment. His manifold activities may be noted by a glance over the programme of the second annual congress of the Canadian Public Health Association, which was published in last week's issue. The work of the engineer, which is peculiarly his own, is also well known. The lack of a clear definition of the relations of the engineer and the health officer has, however, led in the past to an enlargement of the power and duties of the latter beyond, in some respects, what is to the best interest of the public.

The engineer as a sanitarian comes into close touch with the medical health officer. To-day the lines along which the activities of municipal sanitary engineers are being directed are the problems of water supply development, the consideration of sewerage and sewage disposal, the matter of city waste disposal and street cleaning, the proper conduct of construction camps, and the supervision of general health conditions in mining districts and other engineering work.

Quoting Section 93 of the Public Health Act of Ontario, the Act states:—

> "Whenever the Council of any Municipality or any municipal board or commission or any company or person contemplates the establishment of or the extension of or any change in an existing water-works system, they shall submit the plans, specifications, and an engineer's report of the water supply and the works proposed to be undertaken, together with such other information as may be deemed necessary to the Provincial Board, and no such works shall be undertaken or proceeded with until the source of supply and the proposed works have been approved by the Board.
>
> "The Board upon the application for such approval may direct such changes to be made in the source of supply or in the plans submitted as it may deem necessary in the public interest."

Section 94 of the same Act states:—

> "Whenever the construction of a common sewer or of a system of sewerage or an extension of the same is contemplated by the council of any municipality, the council shall first submit the plans and specifications of the work together with such other information as may be deemed necessary by the Provincial Board, for its approval.
>
> "The Board shall inquire into and report upon such sewer or system of sewerage, as to whether the same is calculated to meet the sanitary requirements of the inhabitants of the municipality; and as to whether such sewer or system of sewerage is likely to prove prejudicial to the health of the inhabitants of the municipality, or of any other municipality, liable to be affected thereby.
>
> "The Board may make any suggestion or amendment of the plans and specifications or may impose any condition with regard to the construction of such sewer or system of sewerage or the disposal of sewage therefrom as may be deemed necessary or advisable in the public interest."

We have the greatest of confidence in the Ontario Provincial Board of Health. The work of the Board has been eminently satisfactory in the past, particularly since the present medical health officer, Dr. McCullough, has been installed. In many ways, however, the engineer, from the nature of his education and professional training and experience, is the best person to pass final judgment on questions of engineering practice. It will be agreed that there is a necessity for a central organization to pass on the plans for water supply and sewerage systems throughout the provinces, and it will be conceded that the provincial Boards of Health are the proper bodies for this work, as by this means centralization of authority and responsibility is fixed.

We believe that some means should be taken for having engineering advice given to the Board of Health regarding plans submitted to them for their approval and for advice regarding all the purely engineering details which inevitably arise when questions of water supply and sewage disposal are considered. Some of the provinces have already made provision for such advice by the appointment of a resident sanitary engineer under the direction of the Provincial Board of Health, and with the additional safeguard of employing consulting engineers. We do not offer any suggestion as to the method to be employed in securing this advice, but we must emphasize strongly the necessity for the securing of the assistance of expert sanitary engineering experience to co-operate with the Provincial Boards of Health.

EDITORIAL COMMENT.

The daily press notes another failure of a water turbine, with one man killed and nine others having narrow escapes. We have commented several times before in *The Canadian Engineer* on the fact of so many failures of water-wheel casings. It is a matter purely of hydraulic design, and there is little excuse for these repeated failures.

* * * *

An advance copy of the "Proposed Rules and Regulations for Inside Work" has just come to hand. These rules and regulations have been framed by the Hydro-Electric Power Commission of Ontario with the object of insuring that the design, materials, construction, equipment, workmanship and maintenance of electrical work or installations throughout Ontario, as well as of repairs, alterations or extensions thereto, shall be in accordance with the best current commercial practice, and that the interests of the public, workmen and others, shall be duly guarded, both with regard to safety (to life, limb and property), and convenience. These proposed regulations are being sent out to the different individuals and companies who are directly interested or affected by their enforcement, with a request that they express their criticisms and suggestions for changes and forward to the Commission by the 15th of October. As noted above, this is merely the advance copy, and the final publication will be proceeded with after that date. We would suggest that those interested in the regulations should communicate with the Secretary of the Hydro-Electric Power Commission and secure a copy. This week we are unable to make any comments on the regulations, but next week we hope to draw attention to some of the features where noteworthy change has been made from the old Underwriters' rules.

* * * *

To the looker-on of building operations it appears that there must be a clever organization with special knowledge at hand, and with trained mechanics working under careful supervision in order to successfully handle the building of even a fair-sized structure. But oftentimes, if one examines, he will find the methods crude and extravagant, and that much of the knowledge employed is the result of tradition and custom, and not of keen, original study. The sight of hod-carriers carrying brick to the upper story of a good-sized building is very common, and yet it is a shrewd guess that a hoisting engine, with a proper elevator and stages arranged so that brick could be delivered on wheelbarrows would pay.

GENERAL NOTES.

Cold weather prevailed throughout Canada during the greater part of the month, with a resultant mean temperature below the normal in most districts. The average was slightly exceeded in southwestern parts of British Columbia, and also locally in Alberta and Saskatchewan, but elsewhere in Canada the mean value was in defect by about three degrees.

Precipitation was excessive throughout Canada except in Nova Scotia, Prince Edward Island, and very locally in Ontario where the average amount was not recorded. Exceptionally heavy rainfalls occurred in Quebec and New Brunswick, and also more locally in Ontario. In the Irrigation Belt of British Columbia the rainfall was almost sufficient to supply the crops with moisture. The pronounced feature of the precipitation of August was the large number of days on which it occurred, being in most localities more than fifteen.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for August, 1912:

	Depth in inches.	Departure from the average of twenty years.
Calgary, Alta.	2.7	+0.18
Edmonton, Alta.	4.4	+2.08
Swift Current, Sask.	2.5	+0.61

IRON AND STEEL TARIFF.

Speaking of further extensions of the iron and steel plant of the Lake Superior Corporation, Mr. T. J. Drummond says that the company has decided to postpone definite action pending possible consideration and action by the Dominion Government in regard to the iron and steel tariff.

"The existing tariff in iron and steel," he says, "is so torn up by special dispensations, exemptions and rebates, that the progress of the industry is retarded, and in many cases made absolutely impossible. Under the existing tariff we are encouraged to manufacture in small lines, giving small tonnage, and then discouraged in progression into the manufacture of heavier sections, which give larger tonnage. In other cases industries are practically bonused to purchase their pig iron, merchant steel, etc., abroad, and so in one way and another the industry is hampered, and the tariff is in many cases by these exemptions made absolutely illogical and inconsistent.

"If the iron and steel industry is to go forward this tariff must be overhauled, and such matters as I have referred to must be dealt with in a commonsense manner, and especially in connection with pig iron, merchant mill products and structural steel. At present practically one million tons of iron and steel are annually being brought into the country, and the bulk of this tonnage could and should be made in Canada. We placed our case before the Government during the last session of parliament, and we are hoping that something may be done this session, but pending the outcome of what consideration the Government is giving to our case, we can only mark time, and hope that such action will be taken as will warrant us in going ahead with the extensions we have in view."

◆

A new $5,000,000 steel plant for the manufacture of steel barrels and commercial packages has just been organized at Montreal. A group of influential Canadians, including Sir William Van Horne, Sir William Mackenzie and Messrs. George F. Johnston, C. W. McLean and J. Wesley Allison, have secured from the Steel Package Company of New York the letters patent to manufacture steel barrels and commercial packages of all descriptions. The new concern, it is said, is capitalized at $5,000,000, the financing having been done in New York, and will erect a plant in the vicinity of Montreal. The new concern is to be known as "The Canadian Steel Package Company," and it is probable that Sir William Van Horne will be the first president.

INFORMATION REGARDING WATER-POWERS.

We have just received an advance copy of a pamphlet, entitled "Instructions Relating to the Gathering of Certain Preliminary Information Respecting Water-Powers," to be issued shortly by the Commission of Conservation. The pamphlet has been prepared by Mr. A. V. White, M.E., and copies may be obtained from the secretary of the Commission of Conservation, Ottawa, or from the Department of Lands, Victoria, B.C. As there are only a few hundred available for distribution, those desiring copies should apply at once. An abstract of the introduction to the pamphlet is given herewith.

The inland water resources of the Dominion of Canada are of unique and exceptional value, and exist as a widely-distributed national asset.

During the last few years great attention has been given to the utilization of inland waters. The ability to transmit electrical energy long distances has resulted in an enhancement in the values of water-power sites, which, in turn, has caused persons interested in water-power developments to use, or seek to use, large quantities of water in special ways and for special purposes. Since it is necessary to conserve the common interests of the people in these waters, it is the desire and intention of the Federal and Provincial Governments of Canada, as quickly as possible, to obtain, so to speak, a preliminary inventory of the possible water-powers and other water resources of the country. In pursuing this work, it is very desirable to have the sympathetic and practical co-operation of surveyors, engineers, fire wardens, game wardens, road superintendents, timber cruisers, and others, in assisting to assemble reliable preliminary data relating to the inland waters of Canada. The data thus obtained will greatly assist the various Governments in administering and conserving, in the general public interest, the water resources of Canada; and further, the publication of information relating to our water-powers will, no doubt, materially contribute to the commercial opening up and development of the country.

It may be remarked that the commercial opening up and development of Canada's resources—and to which power is so necessary—will greatly improve the field of engineering activity. This remark is made in order to suggest the fact that hydrographic information gathered by engineers and others, when collectively published, will result in attracting the attention of capital to these water-powers and other resources; and one of the first classes in the community to feel the benefit of such new development is the engineer. Engineers who may be able to assist upon the gathering of the data desired may, therefore, find additional incentive in knowing that their pioneer work will, later on, result in the expansion of the sphere of their operations.

One of the chief objects in acquiring data respecting water-powers is, first, to enable the owners of the rights to know the possibilities and limitations of their powers, [illegible] respecting their possible uses and value; and, second, to enable prospective promoters of water-power development to learn the general [illegible] without the necessity of costly, independent, preliminary surveys. Certainly, if the [illegible]

The natural resources of Canada are being investigated by the Federal Government through the Commission of Conservation, Ottawa. This Commission has recently [illegible] an extensive report entitled "The Water-Powers of Canada." [illegible] the water-powers of Western Canada—British Columbia, Alberta, Saskatchewan, and Manitoba. The Commission, therefore, decided to prepare and issue, as soon as practicable, a report dealing with the water-powers of Western Canada. Work incident to this report has already been commenced.

Guiding Principles.—Speaking broadly, of the annual precipitation upon the earth, about one-half is evaporated; about one-third is "run-off"—that is, it runs off over or through the ground, and eventually reaches the sea; and about one-sixth either joins the ground water, or is taken up in plant structure, or is otherwise absorbed in processes incident to the ground. The natural and cultivated properties of the land on which the rain and snow fall largely determine the efficient uses to which precipitation is applied. It is in this connection that forests are so indispensably associated with the precipitation, and hence with water as a natural resource. Whatever opinion may be entertained respecting the effect of forests in influencing the amount of precipitation, the burden of opinion is that no feature of the topography of the country ministers more efficiently to the gradual and economical run-off from the precipitation than do forest areas. Thus it is that failure to intelligently conserve forest areas has wrought havoc by causing a great destruction of forest floors and agricultural lands, which, humanly speaking, can never be restored, to say nothing of the annual destruction to property by flood run-off, which seems yearly to increase rather than diminish. The run-off is the chief factor entering into water-flow problems as they relate to power development.

A deforested, eroded, and scoured territory, which has lost the humus of the soil, cannot retain the beneficent rains which, instead of being retained in the ground and transmuted into plants by the various processes of growth, carry destruction in the pathways of their torrential run-off. The water is necessary to the soil, and the soil, with its plant growth, is necessary to an economical disposition of the water. The interests of municipal and domestic water supply, water for manufacturing and industrial purposes, irrigation, navigation, and water-power are all interrelated and interdependent. They all depend on the same natural resource—**precipitation.**

In the case of water-power developments, therefore, it would be well to consider whether or not the industries which might use the water-powers would prove to be a menace to the district of their proposed location, and thereby spoil the watershed or waters for other necessary uses. Thus, wood-pulp mills, for example, which might completely denude the timber lands of trees at or near the headwaters of important waterways had better not be established at all; or, if established, then only under the strictest regulation and supervision designed to conserve the forest growth.

Along this line, therefore, in some instances, it may be possible for the engineer, or observer, when making his observations, to indicate what he thinks this or that particular water-power might be used for; whether, we shall suppose, for municipal purposes to serve a neighboring town or settlement, for mining, for manufacturing wood pulp, or, etc. Sometimes some such remarks prove to be suggestive to persons seeking opportunities for industrial development.

Pollution by Factory Wastes.—The effects likely to result from the pollution of waterways by the waste products emitted from the industries utilizing power from these waterways are also very important factors for consideration. The requirement of a pure and sufficient domestic water supply is a vital consideration, and, hence, a class of industrial waste products that will destroy life in the waters into which they are turned must be regarded seriously in their probable influence on human life. If any special instances of stream pollution are observed, it would be well to make a memorandum of such fact. When one realizes how even a great waterway like the Great Lakes System has been polluted, too great caution can hardly be exercised to conserve the purity of our inland waters.

Water-Powers Require Classification.—The amount of water-power is determined by two factors: first, the hydrostatic head, or the vertical distance through which the water may fall; and, second, the amount of water which may be made to operate upon the water-wheels. There are, however, many characteristic features associated with water-powers, which differentiate one power from another, and which determine the commercial and economic values of the individual powers. It is as unreasonable not to differentiate between water-powers as it would be not to differentiate between timber tracts, mineral lands, or the items of any other natural resource varying in quantity, quality, and situation.

In presenting water-power information, effort should be made to make brief remarks upon features which may have special bearing upon any specific possible power sites.

Reservoir Sites.—In connection with the subject of uniformity of flow, one may be on the lookout either for natural reservoirs, súch as lakes, or river expansions, or for natural sites, where reservoirs may be created by means of dams. In such reservoirs the run-off from precipitation may be impounded, and subsequently discharged gradually throughout the year. Water-powers situated within the range of the direct influence of such natural storage reservoirs may be of incomparably greater value than other water-powers not so favored.

When the subject of storage reservoirs is under consideration, it should not be forgotten that Nature also stores her waters elsewhere than in lakes and rivers. Forest floors, extensive areas covered with plant growth, soils and subsoils, the gravel-bed of streams, and the great swamps of the country, each and all, constitute valuable water reservoirs. In such reservoirs there is a widespread and satisfactory distribution of waters, which enables Nature to yield her supplies gradually and as required. A discreet conservation and utilization of such reservoirs will, in general, be found to be much more desirable than some of the large artificially constructed reservoirs, where the liability of accidental destruction of large construction works is always more or less of a menace.

In passing, it may be noted that where an early selection of reservoir sites is made, and the same held under Government control, so that no settlement, railway construction, or other similar improvement, is allowed to take place upon such reservoir sites, the expense and trouble incident to future reimbursement for expropriated properties will be avoided. Hence the desirability of the Government having knowledge of the existence of such sites.

Actual Measurements Required.—When information regarding water-powers is to be gathered, it is extremely important that the data be sufficient, and of the class that will enable a sound opinion to be formed upon the general water interests involved.

But little confidence can be placed in any reports of water-powers not based upon actual measurements, for, without measurements, the best judgment of explorers, and even of engineers, as to the heights of falls and the amounts of water discharging over them, is frequently very wide of the results disclosed by actual measurements.

Reconnaissance Surveys.—When knowledge of the quantities of water-power that may be available in particular places is required on short notice, and when sufficient records of actual observations do not exist, it is possible to **estimate** the probable amounts of power available. For such preliminary estimates, data are secured by what may be termed a reconnaissance survey of the general situation; but it must be recognized that the conclusions reached by such methods are not comparable with the results deducible from actual observations of individual water-power conditions extending over a series of years.

It will be profitable to explain, very briefly, these reconnaissance methods for estimating water-power. First, the area of the watershed in question is ascertained by measurement from the best available maps; to this area is applied an **assumed** run-off coefficient such as would be suggested by a general knowledge of the precipitation, and of the topography, and other characteristics of the territories involved. The wise choice of the coefficient used will, of course, depend upon the good judgment and knowledge possessed by the engineer. This run-off coefficient, as it is termed, is a quantity which represents the amount of water that may be drained off any specified area during a stated period, and is usually expressed as so many cubic feet per second per square mile. Obviously, if the area of a watershed is known to be so many square miles, and each square mile, under specified conditions, will yield so much water, then the total yield of water from the whole watershed will be the product of the factors just mentioned.

When the discharge of a stream, or river, is actually measured, it is usually accomplished by means of floats, or by using a current-meter. The principles involved are very simple. They consist essentially of measuring the velocity of the flow of the stream by means of floats, or meter, and measuring also the area of the cross-section of the river at the place for which the velocity has been thus obtained. The volume of the water which passes a given point is the product of the area of the cross-section of the stream and the velocity of flow at that point.

AUTOMATIC-STOP AND CAB-SIGNAL SYSTEM.

An automatic-stop and cab-signal system for railway signaling, which is being brought to the attention of railway officers, is based on the closed-circuit principle, in which the track rails are utilized for the signal current and no separate contact rails or track devices are required. Adjacent to the end of each block are lengths of rails insulated from the main track circuit, but maintained as a closed circuit through relays at the end of each block. Any obstruction in the circuit of one block, such as a train, open switch, broken rail, etc., deënergizes the relay in the two adjacent blocks in front and rear, and isolates the insulated rail sections from the main track circuit. Attached to the engine is a contact brush or shoe which controls the relay in the cab, and this in turn controls a special valve in the train-line air pipe. The engineman gets a red signal in the cab at a point far enough in advance of the end of the block to give him ample time to bring his train to a stop. In fact, he can pass into the next block at slow speed without causing the automatic device to operate. This, of course, enables him to proceed under control without waiting indefinitely to ascertain how or why the track is obstructed, while at the same time it avoids the undesirability of applying the brakes to a train proceeding under proper control.

The contact brush passing over the insulated rail sections when track circuit is interrupted (by train or other obstruction) deënergizes the relay in the cab, which in turn releases a lock lever, permitting a weight attached to the valve to drop, thus applying the air automatically and bringing the train to a stop. The movement of the valve is automatically recorded, so that it cannot be concealed by an engineman who wishes to avoid knowledge of carelessness in obeying a stop signal. In order to proceed, he must break a seal, thus releasing a lever, which enables him to restore the valve to its normal position. The device mentioned is that of the Thompson Automatic Signal Company, People's Gas Building, Chicago. No installation has been made.

RAIL PLATEWAYS.*

By G. Noble Fell, A.M.Inst.C.E.

Some years ago, the late Mr. Alfred Holt, of Liverpool, and a number of gentlemen interested in the trade of Lancashire and Yorkshire, grasped the idea that if the raw material could be conveyed from the ship direct to the mill, and the manufactured article from the mill to the market, a large saving might be effected in the cost of production. These gentlemen applied themselves to the task of solving this problem, and devised a plan whereby road wagons and lorries could be run over a plateway worked by mechanical means. Unfortunately their efforts were not successful, owing to the heavy expenditure involved in the method devised, estimated at no less than £48,000 per mile of plateway. One can readily understand that at this figure no great saving could be effected over carriage by rail, seeing that the adjacent railways, the London & North-Western, and Lancashire and Yorkshire, had cost on an average £53,400 and £67,800 a mile, respectively. One further realizes another fact, which is that every ton of goods carried over these roads must, besides paying its way, be charged also with its proportion of interest on this heavy capital outlay.

A plateway, pure and simple, that is, a track laid along the public highway to facilitate the passage of ordinary vehicles, is a failure in this respect, and does not meet the requirements of the case. What is necessary is the application on such a track of the best means of propulsion (whether steam, petrol or electric) to work the traffic economically and expeditiously. To do this the track must first of all be removed from the public road, and placed on its own acquired ground. A public road is not the place for such a plateway or railway. There must be provided a suitable permanent way, that will carry a locomotive, a railway wagon and a road vehicle. This is quite practicable, as will be seen by reference to Fig. 1, which shows a special form of plateway rail, a being the space provided for the flanged wheels of the railway stock, and b the space on the same rail allotted to the wheels of the road vehicles. The gauge adopted is 4 ft. 8½ in., so as to allow of the circulation of ordinary railway wagons over the plateway, and it is proposed to carry road vehicles of a width not exceeding 5 ft. 6 in. over the wheel tracks (that is, the measurement from outside to outside of the wheels at ground level), the intention, however, being to construct suitable road wagons for working on the plateway and so to avoid the expense of altering existing wagons to suit railway traction, in such matters as couplings, drawbars, brakes, etc.

The [illegible] rails are laid on a longitudinal [illegible] of concrete or timber and concrete combined, to which they are securely [illegible] by means of [illegible] bolts. The [illegible] rail, [illegible] with the [illegible] ballast, and [illegible] a solid [illegible] footing, and enabling a lighter form of rail to be used than would otherwise be possible.

A further departure from the ordinary methods of railway construction is the [illegible] of a third or centre rail, [illegible] Fell [illegible] as follows. The [illegible] tie above-mentioned is so constructed as to form a chair, raised slightly above the carrying rails. The tie is secured to longitudinal beams, and supports the centre rail, upon which run horizontal wheels. These wheels on the locomotive are worked by a separate pair of cylinders, and are made to grip the rail by means of elliptic springs, thus giving the engine the additional adhesion necessary for overcoming steep gradients. Horizontal wheels with flanges running under the head of the centre rail may also be attached to the wagons and carriages, to guide them round sharp curves, and to make it impossible for a vehicle to leave the track when descending a hill.

Gradients up to 1 in 10 have been successfully worked for many years by this system, and there is no reason why steeper gradients than this should not be overcome, especially where electric traction is adopted. The centre rail is used also for brake purposes, the brake acting directly on the two faces of the rail, giving absolute safety on steep inclines. This brake is operated by a powerful screw working two parallel arms which carry the brake blocks, and practically constitutes a vice gripping the centre rail. It can be worked by hand, or automatically. In the latter case, should a coupling break, the train would be brought to an immediate standstill, even on the steepest incline. With the above system the author has traveled down gradients of 1 in 10, at a speed of 40 miles an hour, with perfect safety. Naturally, on level ground the centre rail is not required, and the engine is worked by the two outside cylinders and carrying wheels alone, and when an incline is reached the driver, by putting the horizontal wheels into motion, can take the train up the hill as easily as it travels on the level. No change of engine, nor even change of gear is necessary, the mere opening of a regulator giving the extra power required. These engines are working on the Rimutake incline in New Zealand, where the system was adopted by the Government for getting over the high ground separating Wellington and Masterton. The saving in cost as compared with a railway of ordinary construction, was estimated at over £100,000.

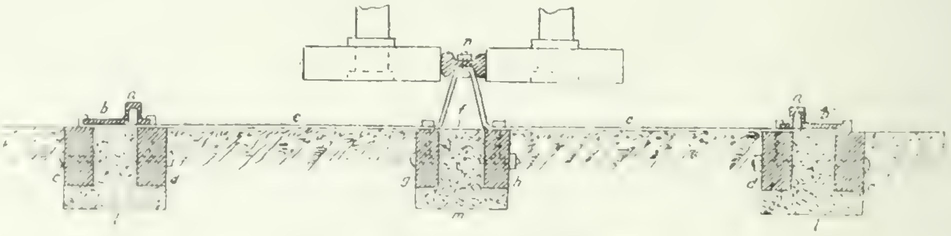

Fig. 1.—Section of Rail Plateway.

A special form of level crossing has been devised for roads, where the centre rail is laid, and means are provided whereby the road vehicles can be removed from the track when required to resume their journey by road, or vice versâ. This is done by tapering the longitudinal guard rails in the direction of the line, so as to form an incline, up which the wheels of the vehicles can be drawn to the level of the roadway. The same means will apply to stations, and to other points where it is desired to rail or derail road vehicles, thus giving agriculturists, manufacturers, mineowners and others, advantages such as are not and never have been possible with the present form of railway construction.

It may here be noted that plateways are not intended to and cannot compete with existing railways; they are to become feeders, and to constitute a means of bringing traffic to them and distributing traffic for them, in a more expeditious and economical manner than has hitherto been possible. They will form an intermediate means of transport, and will perform what neither the railway nor the highway is capable of doing, that is, they will combine the special functions of both.

---

*[illegible] read before the Society of Engineers, [illegible]

In order to keep the cost of construction as low as possible, and so to bring these plateways within the means of every district not possessing railway accommodation, the axle loads will be limited to 5 tons, that is to say, a 10-wheeled locomotive not exceeding 25 tons in weight, will be sufficiently powerful to deal with the class of traffic to be carried, and will be capable of working on the gradients above-mentioned. As the gauge of 4 ft. 8½ in. will be adopted, the ordinary light stock of the existing railways will be able to run over the plateways, and transhipment of freight will thus be avoided. There is no reason why road motors (steam, electric, or petrol) should not utilize the plateway.

Several types of plateway have been studied, that shown in Fig. 1 being designed to carry locomotives up to 25 tons weight, and ordinary railway trucks weighing 10 tons loaded, or bogie trucks weighing 6 tons each and carrying a load of 14 tons. This type is laid with two specially rolled-steel rails, weighing 50 lbs. per lineal yard, carried on the longitudinal timbers c d, to which they are spiked in the usual manner. These beams are in their turn carried on, and bolted to, concrete foundations, the upper surfaces of which correspond with the ground level. The two rails are braced together by the steel tie-bar e, whereby the gauge of the line is kept in proper adjustment. On steep inclines this tie-bar also serves the purpose of supporting the centre rail, as it forms a chair (shown at f), to which the rail is bolted and fish-plated in the usual manner. This chair is carried on, and secured to, two longitudinal beams g h, laid in concrete, and the whole permanent way is thus framed together in a very solid manner. This form of permanent way, including the centre rail and foundations, is estimated to cost £1,300 per mile, calculating labor and materials at average present-day prices.

Taking as an example a mile of plateway, carried along the side of a hill, with, say, an inclination of 1 in 10 (1 in 40 would represent the gradient upon which an ordinary railway would be constructed) over moderate ground, that is calculating upon an average depth of bank and cutting of 5 ft., and an average width of 24 ft. of land required or about 3 acres to the mile, we have the following cost:—

Cost of One Mile of Centre-Rail Plateway.

Single line.	Gauge. 4 ft. 8½ in.
1. Land: average price £50 per acre..............	£ 150
2. Earthwork; average cost 1s. 3d. per cubic yard	515
3. Bridges and culverts	500
4. Permanent way, Fig. 1, including sidings......	1,445
5. Stations	250
6. Fencing; double for the whole distance........	260
7. Level crossings	100
8. Telegraph	80
	£3,300
Contingencies, 10 per cent.	330
	£3,630
Rolling stock	750
Legal expenses, administration, engineering, and interest during construction	620
Total cost of construction and equipment.	£5,000

A plateway constructed on this system over a hilly country and capable of hauling traffic up inclines of 1 in 10, may therefore be built for £5,000 a mile. The cost of an ordinary railway, over similar ground, would be from £10,000 to £15,000 a mile, besides the cost of the extra length of line that would be required for reaching the same altitude with a 1 in 40 grade.

Having found the cost of the plateway, let us see what will be its carrying capacity. Take a line 20 miles in length, divided into three sections, and suppose that there is a length of 5 miles at each end with gradients of 1 in 10, and that the intervening portion is undulating country with normal grades, which would represent a line rising from sea-level to a plateau at an elevation of 2,640 ft., and falling again to sea level, that is, a line connecting two valleys separated by a broad range of hills. At speeds of 15 m.h. on the level, and only 8 m.h. up, and 15 m.h. down the inclines, the journey can be made in 1 hour and 35 minutes, and by running the engine a double trip on the first incline, so as to give a full load for the rest of the journey, the round trip can be made in 5 hours, allowing ample time for shunting, coaling, etc. A centre-rail engine of 25 tons weight will take behind it a gross load of 49 tons up a grade of 1 in 10, or a net paying load of 28 tons; the net double load will therefore be 56 tons, and one engine could make three round trips in 15 hours, carrying a total net load of 336 tons. With four engines running, therefore, 1,344 tons may be carried in a day, or a total paying load of 403,200 tons in 300 working days.

Instead of a double-headed rail, an H or channel bar may be used as a centre rail where the traffic is light. The carrying rails may also be formed of T bars. With this form, however, it will be necessary to provide a flange for keeping wheels of the road vehicles on the track where the centre rail is not laid. The cost per mile of this type of permanent-way, including the centre rail, is £920, and the estimated cost of one mile of plateway is £3,750 over a hilly country and £2,500 a mile on fairly level ground.

An example of a light railway of this description, where light timber viaducts were substituted for heavy banks and cuttings, is the Torrington and Marland Railway, in North Devon, mentioned in Mr. Vernon-Harcourt's work on "Railway Construction." It is eight miles in length, the gauge being 3 ft., and although there are many viaducts of from 20 to 25 ft. in height, and a bridge of three 45-ft. spans, and 40 ft. high, over the River Torridge, the total cost of construction was only £20,000, or at the rate of £2,500 a mile. It was opened in 1880, and is still carrying a heavy mineral traffic. It is intended to utilize similar light viaducts in timber or steel for the system of plateways now proposed, in order to secure economy and rapidity of construction, and this method, combined with plateways and the centre-rail system of traction, will be an entirely new departure in railway building.

The following table gives the cost of working the Torrington and Marland Light Railway, for the year ending December 31, 1911. The cost of management is not included in these figures.

Locomotive Account.

	£	s	d	£	s	d
Coal	300	13	8			
Oil, waste, packing, etc	120	[illegible]	6			
Repairs and renewals	[illegible]	15	10			
				£890	12	0

Track Account.

Rails	194	11	2			
Viaducts	61	3	11			
Sleepers	36	16	6			
				292	11	7

Wages Account.

Platelayers, drivers, stokers, etc..				1,231	4	11
				£2,423	8	6
Less cost of transfer to and from own trucks to L. & S.W. Railway at [illegible] Station	430	9	0			
Distributing and collecting trucks	234	18	0			
				665	7	0
Actual cost of working				£1,758	1	6

£1,758 1s. 6d. ÷ 35,326 tons = 11.97d. (say 1s.) per ton. One shilling per ton for 8 miles = 1½d. per ton-mile.

◆

THE VALUE OF SAWMILL REFUSE AS FUEL IN GAS PRODUCERS.*

By Chas. E. Snypp.

I will endeavor to state briefly my experience in the firing of the following fuels in gas producers, namely, bituminous coal, anthracite, coke and coke braize, and sawmill refuse.

Our producer plant was installed for the purpose of burning Pittsburg bituminous coal, guaranteed to furnish gas of about 125 B.t.u. to the engines. As a matter of fact, we operated the plant continuously for about four years on various kinds of coal.

The producer we used was a pressure type Wood producer. The capacity of the producer plant was 840 h.p., consisting of a combination of three units each having a producer shell 8 ft. in diameter by 12 ft. high with steam jacketed top; one wet scrubber 5 ft. by 18 ft. high; one dry scrubber 8 ft. in diameter by 3 ft. high; one pressure fan; one gas holder and one [illegible] mechanical tar extractor.

The coal was locked in through an air-tight hopper into each of the producer shells. When the workmen poked the fires, the gases under pressure from the blast escaped freely through the poke holes, causing great distress to the workmen. To overcome this difficulty we installed a fan between the dry scrubber and the tar extractor, intending to bring the producer shells under a slight vacuum. This relieved [illegible] though it did materially reduce [illegible] from the poke holes, thus re-[illegible]

[illegible]

then to a dry scrubber, which is a shell about 8 ft. in diameter and packed with excelsior in layers. The gases then pass through an exhaust fan to the holder and thence to the engines.

The first coal that we burned was Pittsburg bituminous coal, but we found that while this fuel filled the requirements as far as the richness of the gas was concerned, our plant went out of commission at regular intervals in consequence of tar congestion. These intervals came closer and closer together the longer we operated the plant on this coal, on account of greater and greater accumulation of its peculiar tar. In fact, the tar was too heavy for the centrifugal tar extractor, and breakdowns of this machine were frequent. This led us to try other bituminous coals with the idea of reducing the tar nuisance.

After four years of continuous service of the producer plant on various bituminous coals we found that in spite of our selection the whole system of pipes and engines was becoming congested with tar. We also found that it was quite an expensive repair to remove this tar from the engine cylinder rings. In fact, many of the rings had to be cut from the grooves with a cold chisel. We found that a gas plant could not be run for more than five hours on gases from Pittsburg bituminous coals without taking out these tars, as the valves and piston rings would stick. Alabama coals did not do much better.

These Alabama coals were analyzed particularly for fixed carbon and volatile matter in order to select those with a high fixed carbon and a low volatile matter. They gave greater satisfaction because of the reduced quantity of tar, and at the same time furnished a gas that was just as rich as the Pittsburg bituminous, namely, about 125 B.t.u. The Alabama coal, however, introduced a trouble peculiar to itself, which finally forced us to abandon it. The first trouble was that the fuel came to hand of irregular quality, even from the same mine, particularly as to volatile matter and ash. The content of ash was especially unsatisfactory and very irregular, varying from 6½ to 11 per cent. Not only was the content of ash high, but it had the peculiar property of fusing in the producer or forming a solid clinker, which was almost impossible to penetrate with poke bars, and even after penetration with bars and sledges was not brittle enough to break in pieces of a size that could be readily removed from the producer itself. Besides this, the act of fusing cuts off the air from the fuel beds, producing a lean gas, or one low in B.t.u., finally putting that particular producer out of business.

We next resorted to the experiment of burning anthracite coal. Our experiment was limited to a few tons, but the conclusion reached was that we could not produce a gas high enough in heat value. The best condition did not yield much more than 100 B.t.u. in the gas. Besides, this fuel was to expensive.

The next experiment was to substitute coke and coke braize for anthracite. This furnished a fair quality of about 100 B.t.u. gas in the beginning, but we experienced great difficulty in the producers filling up with ash, and the ash fusing, thus causing cavities which could not be poked out. The quality of the gas sometimes fell as low as 80 B.t.u., thus putting the plant out of commission. When this happened we would have to [illegible] down and sledge the clinker. I realized that when the gas became lean we could raise the heat value of the gas by feeding the producer with [illegible]

During this interval [illegible] improvements on the producer plant were made, as follows:

---

*[illegible]

First, the "Z" pipe which conducts the gases from the producer shell to the wet scrubber would frequently become clogged with dry soot, and we found that on account of the bends in the pipe this soot would bake in hard clinkers, thus reducing and eventually choking the pipe. This pipe was replaced by a horizontal pipe extending between the producer shells and the wet scrubber, and a partition was run vertically in the wet scrubber, thus making a downtake which opened directly into the bottom of the wet scrubber.

Second, we found that tar was accumulating in the bottom of the wet scrubber and was very difficult to remove. The metal bottom was replaced by a water seal, extending all over the bottom of the wet scrubber. All other pipes where the gases have a downward trend and a sharp bend were similarly provided with water seals, in order that the tar might readily drop out and wash out, thus facilitating the cleansing of the producer.

While these water seals or water bottoms are essential to the cleansing of the plant, the following little experience will show that they must be used with some judgment. The wet scrubber as installed by Woods & Co. in the ordinary sized machine is about 5 ft. in diameter. The metal bottom of this scrubber was removed, as I have just stated, and a water seal substituted, which proved to be just the thing for a pressure producer. However, I was called upon some months later to go to a plant in Mississippi where they were having trouble with their producer. Upon my arrival I was surprised to see how nicely the producer was working, and noticed that the installation consisted of 140 h.p. engine together with a corresponding size producer of the suction type. In spite of no apparent difficulty, everybody seemed to be afraid to approach this producer, and the superintendent told me to wait awhile and see what would happen. I did wait awhile and noticed that the engine was drawing gas under a head of about 3 in. of water and this was gradually increasing until some hours afterwards it reached 5 in., and then ran rapidly to 10 in. Then there was a terrific explosion which blew through the seal and blew the poke hole castings and the plugs from the top of the producer. The negro stoker happened to be on top handling a wheelbarrow of coal, and he must have been a new hand or a nervous one, as the last I saw of him was that he was tumbling toward the ground with the wheelbarrow of coal, a distance of about 15 ft., and I noted particularly that he landed on his feet and ran down the hill-side. The only reason that I did not leave was that I was penned in by a guard rail. The after-effect of this explosion was that the remaining water seal was alternately drawn in and expelled by numerous puffs that followed. It was apparent to me at once that what had really happened was that the engine had drawn up the water from the seal and admitted a large influx of air, which no doubt made the proper mixture for causing an explosion. The remedy applied was very simple. The opening on the water seal under the scrubber was restricted in size so that no great quantity of water could be drawn in suddenly. The plant ran along afterwards without any trouble whatever, with simply working the beds and removing the clinker when the draft became obstructed. You will pardon this digression.

On account of these various troubles and because of the increase in heating value of producing gases made with barrel staves referred to before, I was prompted to try sawmill refuse in the producers, and found very much to my satisfaction that we were able to operate the plant continuously on about 130 to 135 B.t.u. gas, and the plant was more reliable on account of the even quality of gas. After about a month of use of this refuse fuel our tar troubles began to disappear, and now after using this fuel for a couple of years it is a very rare occurrence to have an inlet valve or an exhaust valve stick in the engines on account of tar, or carbon deposits. In fact, we have discarded the dry scrubber altogether and we even operated one week without a tar extractor at all, on account of that machine needing repair. This illustrates how well the sawmill refuse has solved the problem in our case when it is recalled that we could not run even five hours on coal without removing the tar.

The refuse that we use is known as "cypress hog." It consists of about 50 per cent. of sawdust and 50 per cent. of chips, such as are discharged from the "hog," which is a machine used by sawmills to destroy their refuse. This material runs from 30 to 55 per cent. moisture, and this moisture seems to be necessary for best working conditions.

I will state that we have to guard against the sawdust blowing over into the pipes which conduct the gases to the wet scrubber. This is a probably local trouble, due, no doubt, to the strength of the blast that we use in order to get capacity. We have been able to realize full capacity using sawmill refuse, and our engines deliver a brake horse-power on about 4½ lb. of this fuel.

The changes necessary to fire sawmill refuse are merely the removing of the coal dump hoppers and substituting a hollow cylinder about 10 ft. high slightly tapered and made larger at the bottom and fitted with a slide gate at both top and bottom; these slides are worked with levers and the sawmill refuse is locked into the producers through these tubes.

To start firing a producer with sawmill refuse it is not necessary to have an underlying bed of cinders or ash to cover the blast pipe. The fuel can be dumped in on the water seal and fire can be started either on top or through the side poke holes. Aside from these conditions, the beds seem to be subject to all conditions prevalent in the firing of coal. A clinker is formed of a brittle nature and can be easily removed with the fine ash. The percentage of ash is so small that a producer can be operated about three weeks before removing the ash.

Cavities and chimneys will burn in the bed, and eternal vigilance and poking are necessary to produce a uniform quality of gas. In order to lessen the labor of poking it is good practice to feed occasionally, say, once a day or when the quality of the gas fluctuates, one or two charges of blocks ranging in size from stove lengths to 15 in. in diameter. These blocks will find their way into the cavities and stop the chimneys, and the producer will respond instantly. I have had cavities form low down in the beds and cause trouble, but we have always succeeded in poking down overlying fuel and closing this cavity.

We also experimented with "pine hog," and we find that it is more efficient fuel for producer gas than "cypress hog." An average of ten analyses made on gas produced from "pine hog" showed 161.4 effective B.t.u. against 130 to 135 for cypress. The reason for this is probably due to the greater heat value of pine itself as compared with cypress. The analyses of heating value of these two fuels showed that the cypress was 5 540 B.t.u., while pine was 7 605 B.t.u. These are on fuel as received, and, therefore, include moisture. The only reason that we do not use pine is that cypress is more available as far as our plant is concerned, which means that it is cheaper, comparatively speaking, although it is pound for pound a much richer fuel.

I have added below a number of analyses of gas produced from various kinds of fuel that it has been my lot to experiment with in solving our problem.

Kind of Fuel.	No. of Analyses.	Effective B.t.u.	CO.
Pittsburg bituminous	15	125.3	9.6
Pittsburg bituminous	6	119.0	9.5
Pittsburg bituminous	8	122.5	9.7
Alabama and Pittsburg bituminous	3	112.7	11.3
Alabama bituminous	9	140.9	9.3
Alabama bituminous	12	112.2	7.8
Alabama bituminous (Rock Castle)	13	104.4	11.4
Pocahontas coke	10	103.1	...
Pocahontas coke	8	97.8	7.2
Nut coal	3	100.4	10.5
Coke braize	2	[illegible]	10.1
Coke braize	4	113.8	...
Coke braize	4	108.0	6.4
Anthracite coal	39	91.2	12.4
Anthracite coal	11	101.2	9.1
Cypress hog	4	111.3	12.2
Cypress hog	12	134.2	10.3
Cypress hog and petroleum	5	135.0	...
Cypress hog and petroleum	5	135.0	..
Pine hog	11	161.4	9.9

To summarize; the advantages to be derived from burning sawmill refuse where it is available are as follows:

First, little ash, therefore little cleaning to be done.

Second, high grade gas, i.e., gas of higher heat value as compared with other fuels in our type producer.

Third, a lesser quantity of tar, and much more limpid in character.

Fourth, gas of constant quality with less labor.

Fifth, no deadly gases to overcome the workmen.

Sixth, and finally, the all-important factor of lower cost per h.p. hour must not be forgotten.

In conclusion, I wish to explain that there is no intention on my part of casting any reflection on the producer or the original installation that we had. I believe that we were among the first to burn bituminous coal in our section, and our work was of such character that the producer plant had to be operated twenty four hours a day and sometimes on Sundays.

NEW TECHNICAL SCHOOL IN WINNIPEG, MANITOBA.

The St. John Technical High School was recently opened for the admission of pupils. This high school has been established to provide a more complete and comprehensive scheme of scientific and technical education for students and the ordinary school age who are able to continue their education with a view to special preparation before entering the university or commencing a commercial or manufacturing career. Students may by arrangement take a mixed course slightly different from those laid out, with the object of training for definite occupations.

The first year's course consists of such subjects as English, commercial geography, elementary bookkeeping, practical arithmetic, simple algebra and mensuration, geometrical and mechanical drawing, general elementary science, and practical work in the laboratories and workshops.

In the second and third years the subjects are grouped into courses under: Architecture and building; electrical work; machine work; chemical industries, and commercial work. The courses have been carefully arranged by experienced practical teachers, fully acquainted with the requirements of various occupations and knowing well what subjects of study are necessary in the best interests of students who have the desire to achieve success in their chosen occupation.

In connection with the teaching of the mechanical work, the most complete arrangements have been made in the basement of the building. Here, where the noise will not disturb the other classes, are rooms fitted out with the very latest of mechanical appliances and various sorts of machinery from which the intending electrician or mechanic can learn at first hand. In the machine shop, for instance, there are no less than 11 lathes of the very latest pattern all driven by electricity. Besides the large and small lathes there are also to be found a large planing machine, two milling machines, a tool making machine and other fine pieces of machinery all with particular uses.

The cement floor is covered with a wooden flooring so that sharp instruments falling thereon will not be dulled or chipped.

Next to this room is the forge room where the art of the blacksmith and all appertaining to it is taught. The large room is a mass of anvils and blowers and the various instruments that go with the trade. The electrical laboratory is also fitted out with the very latest appliances.

There is a large room for mechanical drawing fitted with monster blackboards running to the full width and length of the walls. Pattern making, wood turning and forging, practical woodwork, all are prepared for in a manner that is excellent. The domestic section where the domestic science and art are taught are equally well equipped. A large power hammer has been installed in the forging and tempering room which will show interesting comparisons between hand and power work. The carpentering department is also most elaborately fitted out and it will need but a few days for the entire system to be running smoothly. At present workmen are fitting up the various machines and getting everything ready.

G. J. Price is in charge of the technical work and H. J. Russell will look after the commercial work. There is ample room in the building for a large number of pupils. A feature is the large lecture hall fitted out with a stage and with a large gallery, accommodating close upon [illegible] all told.

A COMPLETE SEWAGE DISPOSAL PLANT FOR A PUBLIC INSTITUTION.*

By T. Lowes, Chief Assistant to T. Aird Murray, Consulting Engineer, Toronto.

Of course it is impossible to bring before your notice any one complete system of sewage disposal for a large isolated building, and say that such is the best or only efficient system applicable to all such buildings. Just as with reference to towns and cities, it is foolish to assume that any one system of sewage disposal is always suitable. Local conditions must always govern the choice of any system. While the scientist may say and prove that such and such systems will produce effluents which cannot be objected to either from the nuisance or the health point of view, there are many local engineering factors which may decide the choice of a system apart from the theoretic suitability.

The chief engineering factor is, after all, the question of fall or level between the outlet drain and the point of main outfall. Given plenty of fall which will allow of complete processes of sedimentation and filtration, we have at once ideal conditions in which our choice of a system is hardly limited. With ten or twelve feet of fall between the point of drainage discharge and the effluent discharge almost anything can be done. Local conditions mean something more, however, than plenty of fall, and may be said to include as follows :—

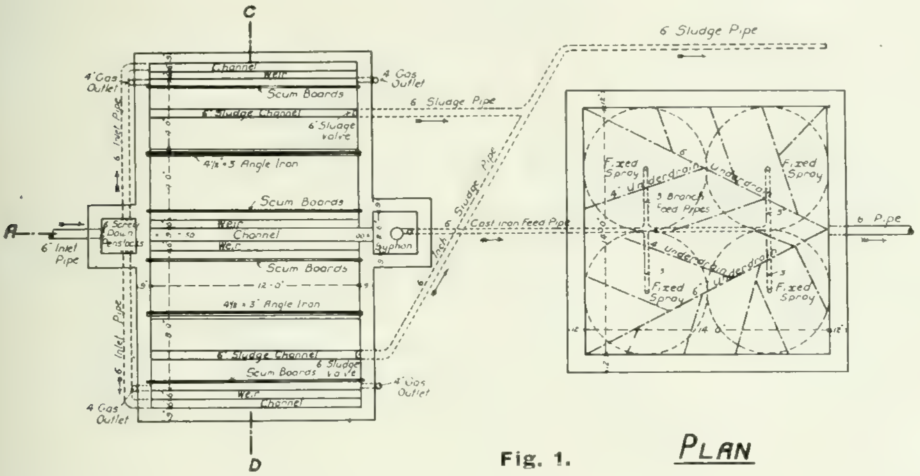

Fig. 1. PLAN

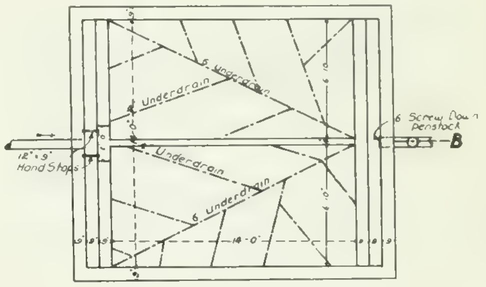

Fig. 4.

(a) The quality of final effluent demanded.

(b) The character of land and subsoil available for disposal works.

(c) The volume and character of stream, river or lake receiving the final effluent.

(d) The amount of surface of land available for works.

(e) The vicinity of any projected works to other buildings.

(f) The character of the building producing the sewage, whether used for domestic or trade purposes.

(g) The economic working of any plant with reference to the supply of labor for operating purposes.

The above and many other minor considerations all effect the final choice of a scheme of sewage disposal.

We are apt to hear too often that such or such a system has proved most successful in such or such a location, and that this is, therefore, practically "the system of sewage disposal" to be relied upon. The purely scientific mind too often sees only the scientific working and the results, without due consideration to particular adaptability, and when the engineer finds that he has to adapt this particular system of sewage to some particular location, he is, to use a slang term, "up against it."

In the above reference too much stress cannot be laid upon the absurdity of any tendency on the part of health authorities to dictate special systems of sewage disposal as being applicable without reference to local conditions. The medical officer or medical inspector may have in his own mind the fact that certain methods have, to his knowledge, given success; but, he has no justification for recommending such methods until he has become thoroughly familiar with the topographical and engineering factors which have particular application to the case in point.

This paper is not intended to be a treatise upon the various methods of sewage disposal which may be applied to isolated buildings, but merely a short description of a method which the author lately designed to suit certain conditions which came before him in connection with the Northumberland and Durham counties House of Refuge, at Cobourg, Ontario.

By an isolated building is meant a building producing sewage without the use of any common or public sewer, and where it is necessary that the sewage be so treated that it will not produce any nuisance to the occupants of the building or to others in the vicinity.

The House of Refuge is located some considerable distance from the town sewerage system, upon rising ground which gradually falls to a clear water stream which eventually discharges into Lake Ontario. The stream forms the natural surface drainage for the land and valley in which the House of Refuge is built, and has continued ever since there has been sewage from this building to take the discharge. The stream flows through part pasture land and part urban land to the lake. Complaints have been made from time to time of pollution of this stream.

A few years ago a sewage disposal system was installed in a field south of the "House." This system included a small receiving chamber, and a septic tank. At one time the discharge from the septic tank was conveyed direct to the stream, but an injunction was obtained by a land owner, for prevention of nuisance and pollution of the stream. This injunction was followed by cutting off the effluent drain, and substituting a system of sub-irrigation by discharging the septic discharge by means of a syphon below the surface of the land at depths ranging from 1 foot to 1 foot 6 inches. It was not long before the land showed signs of becoming sewage sick, until last year the local nuisance and sewage odors from the land became unbearable.

---

* Paper delivered at 2nd Congress of Canadian Public Health Association, Sept. 17th, 1912, Toronto.

In the first instance the system failed because the land was of stiff clay and entirely unsuitable for purposes of either surface or sub-irrigation.

In both cases the system failed because it did not meet local conditions.

The fact that a septic tank in some other locality discharging probably into a large volume of water where it may only have been necessary to remove grosser solids, had no application in this case. Again the fact that septic discharges may have been discharged with a certain amount of efficiency into friable sandy of gravel land and lost by evaporation, absorption and oxidation, did not apply in this case. The history of the sewage disposal of this House ol refuge was one of finding out by experiment what the local conditions were, instead of first examining the local conditions and designing a system to suit them.

The local conditions as summed up by the author may be stated as follows:—

(a) A House of Refuge providing accommodation for about 100 people, producing on the average about 3,000 gallons of sewage per day of 14 hours.

(b) Ample fall from the base of the building to the stream receiving the final effluent.

(c) A small field presenting about 15 feet of fall located about 60 yards south of the "House" and the property of the "Counties."

(d) A character of subsoil in the neighborhood entirely [illegible]

(e) A stream capable of receiving the volume of sewage discharge, if it was rendered (1st) non-putrescible, and (2nd) non-pathogenic.

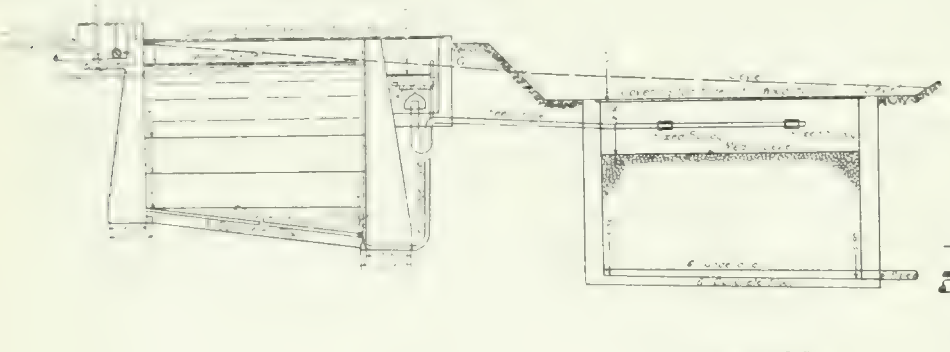
The particular field south of the "House" on which the [illegible] was selected for the new [illegible]. Owing to the [illegible] character of the land and its proximity to the main road, it was considered that [illegible] of the type which has been called "Biological," providing artificial filtration and ignoring [illegible]

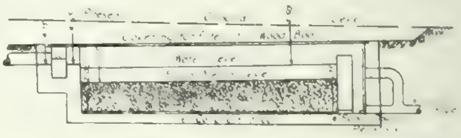
[illegible]

[illegible] percolating filters.

[illegible]

[illegible]





SECTION A-B

Fig. 2.

Fig. 5.

tion tank. The tanks are provided with scum boards to keep back floating matter, while the principle of immediate separation of the precipitated solids from the flowing sewage is adopted by provision of a wire reinforced glass apron covering the sludge storage area. The sedimented liquid is passed into a syphonic discharge dosing chamber, and then by means of 6-inch cast iron pipes to four fixed sprays, where it is distributed over the surface of a percolating filter consisting of coarse gravel from 1 inch to 1½-inch cubes in size. The percolating filter is never in a state of saturation but every drop of the liquid sewer is exposed to atmosphere during its downward course. The filter is well underdrained as shown. The oxidized liquid is then passed on to the final sand filter. Fig. 2 shows a section through the sedimentation tank and filters, while Fig. 3 shows a cross section of the sedimentation tank, location of the sludge apron, scum boards, and slopes for movement of the sedimented sludge to the storage area. At the apex of the sludge apron and under it, air pipes are fixed to take care of the gases produced by the decay of the stored sludge. The arrangement is intended to produce a sludge which is thoroughly septized and innocuous from a nuisance point of view.

Figs. 4 and 5 show respectively a plan and section of the sand filter treating the oxidized effluent from the percolating filters. These filters are in duplicate, so that either can be used independently to allow of cleaning and removal of sand. One foot three inches head of liquid is provided over the surface of the sand in order to overcome the friction of the sand particles, while a value and base outlet is used for emptying the filters at any time.

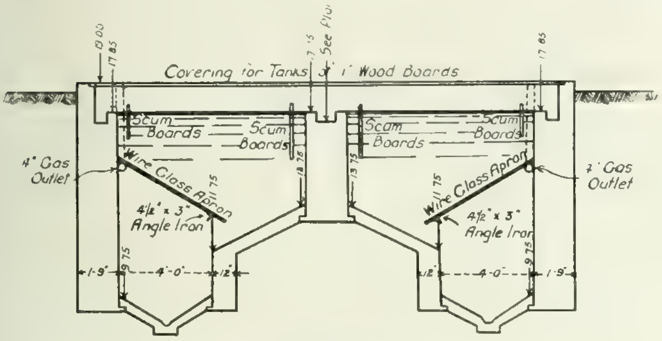
The system is, generally, based upon the following capacities and dimensions:—

Sedimentation tanks in duplicate 12 ft. 0 in. by 4 ft 0 in. by [illegible] at sludge outlet end, with a capacity of [illegible] gallons, or at 3,000 gallons per day of 14 hours equal to 21 hours' flow. At certain hours of the day the flow per hour will exceed the above ratio considerably. The average velocity flow through the tanks is approximately .3 feet per minute. The sludge storage area has a capacity of [illegible] cubic yards, and approximately a storage capacity of about from three to four months of 85 per cent. water and sludge residue, based upon [illegible] sludge of purely domestic sewage. It is [illegible] that the sludge will require removal after from [illegible] to 4 months' septic action to sludge drying area. [illegible] provided at a level to which the sludge can [illegible] from the base of the tanks.

The percolating filter is 14 ft. .0 in. by 14 ft. .0 in. by [illegible] cubic yards. [illegible] gallons per day the rate of filtration will, therefore, [illegible] This is a much less rate than [illegible] on account of the use of pebbles in lieu of clinker or broken stone. It is anticipated that this [illegible] to arrive at maturity, the [illegible] filters being from 1 to 2 months.

The sand filter is 14 ft. .0 in. by 14 ft. .0 in. by 2 ft. .6 in. in depth, well underdrained, as shown. The square surface is 196 feet, the rate being slightly over a half million gallons per acre of surface.

The work of construction was let by tender to Mr. Roland McLaren, of Oakville, Ontario. Work was commenced on or about the 1st of June this year, and finished, apart from the housing, in the middle of August. The whole system, together with effluent drain to stream and housing, including cost of a resident engineer, has totalled approximately $3,000.



SECTION C-D

Fig. 3.

The plant has not been sufficiently long in operation to allow of analysis of the effluents from the various parts to be made, but it may be said that the effluent at present is pure in appearance to sight and odor. Regular samples of the effluent will be taken from now on and the results published in the Canadian Public Health Journal.

TEMISKAMING RAILWAY FINANCES.

The following is the condensed statement of revenue account of the Temiskaming and Northern Ontario Railway for the year ended October 31st, 1911, compared with the year 1910:

	1911.	1910.
Revenue from transportation ..	$1,708,249.02	$1,522,020.05
Revenue other than transportation	72,715.81	69,831.97
Total operating revenue ..	$1,780,964.83	$1,591,852.02
Operating expenses	1,181,998.63	1,165,361.36
Net operating revenue	$ 598,966.20	$ 426,490.66
Ore royalties	17,060.56	31,762.92
	$ 616,026.76	$ 458,253.58
Hire of equipment, etc.	22,874.07	22,123.27
Total earnings	$ 593,152.69	$ 436,130.31
Paid Treasurer of Ontario	515,000.00	420,000.00

The operating expenses amount to 66.4 per cent. of the gross earnings, and the net earnings to 33.6 per cent., as compared with 73.2 per cent. and 26.8 per cent., respectively, for the twelve months ending October 31st, 1910.

The total mileage of the railway, including main and branch lines, yards and siding is 379.62.

CANADIAN CANAL TRAFFIC.

Canadian canal traffic from the opening of navigation until July 31 of this year has exceeded by approximately 3,000,000 tons the traffic for the corresponding period of last year, as shown by statistics just issued from the department of railways and canals. The increase is about 16 per cent. The total tonnage through Canadian canals for the period mentioned this year is 20,116,188 tons, as compared with 17,154,111 tons for a similar period last year. The increase in correct figures is 2,962,077 tons.

The Soo canal, leading all others in volume of traffic, shows the largest increase, being 2,793,682 tons, or almost equal to the total increase throughout all the canals, a decrease in the volume of tonnage through the Chambly, Rideau, St. Peters, Murray, and Trent considerably offsetting in the totals what would otherwise have been an enormous increase over last year.

As against the decrease in those above mentioned, large increases are shown in the volume passing through the Welland, St. Lawrence and Ottawa, while St. Andrews locks on the Red River above Winnipeg shows probably the highest proportionate increase of all, the volume having jumped from 11,241 tons last year to 50,063 this year, or an increase of 38,822 tons.

The statistics for the various canals are as follows:

Canal—	1911.	1912.	Increase.
Soo	14,028,453	16,823,135	2,794,682
Welland	1,138,284	1,201,588	03,304
St. Lawrence .	1,339,766	1,417,731	77,965
Chambly	273,356	257,374	*15,982
Ottawa	134,990	173,563	38,573
Rideau	80,439	76,243	*4,196
St. Peters ...	29,473	24,860	*4,613
Murray	86,206	68,475	*17,731
Trent	30,903	23,156	*7,747
St. Andrews .	11,241	50,063	38,822
Totals	17,153,111	20,116,188	2,963,077

---

*Decrease.

The large increase at the Soo is chiefly made up from the tremendous volume of iron ore passing through, this being partly American traffic handled by American vessels. There has also been a large increase in the volume of Canadian wheat conveyed.

Of the total traffic passing through the Soo, over **82 per** cent. was purely United States' traffic.

The statistical branch of the department of railways and canals is this year collecting figures showing comparative rates by water on the canals, as compared with those by rail and are requiring all shippers to supply a statement of rates. It is purposed that the scheme be elaborated next year so that these figures will be analyzed according to canals and also commodities.

RAILROAD EARNINGS.

The following are the railroad earnings for the week ended August 31st:—

	1911.	1912.	Increase.
C.P.R.	$3,329,000	$3,809,000	+ $480,000
G.T.R.	1,442,953	1,660,916	+ 217,963
C.N.R.	460,900	563,800	+ 102,900
T. & N.O.R.	58,451	58,451	— 13,205
Halifax Electric ...	8,532	7,699	— 833

The July statement of the Grand Trunk Railway system shows a total decrease of £14,450 sterling. The earnings of the Grand Trunk proper show an increase of £10,300, but the subsidiary companies show a substantial decrease: Grand Trunk Western Railway, net profit decreased £2,200; Grand Haven & Milwaukee Railway, net profit decreased £10,150; Canada Atlantic Railway, net profit decreased, £12,400.

The gross earnings of the C.P.R. for the month of August, as given in the weekly statements, show an increase of $1,813,000, or 18 per cent., over earnings in the same month last year. August earnings were $11,886,000 against $10,073,000 for August, 1911.

PRESIDENTIAL ADDRESS TO THE SIXTH CONGRESS OF THE INTERNATIONAL ASSOCIATION FOR TESTING MATERIALS.*

By Henry M. Howe.†

The purpose of this association is to serve humanity by enabling it to distinguish the fit from the unfit among the materials with which the world's work is done, the materials for its buildings, its bridges, its ships, its railroads, its machinery, and its constructions in general. This is the function of the testing engineer; he stands between the public and the manufacturer who would supply that public, to test the fitness of those supplies, to measure accurately their degree of fitness, and to reject unsparingly the unfit. He is a guardian of the lives of those who travel by land or sea, and of those who live or work in buildings of important size. He is a protector of the material interests of the public, because in the last analysis all structures and all materials of which they are made are for the use and benefit of the public individually or collectively, and are paid for directly or indirectly by that public; and it is to the interest of that public that the fitness of those materials for their various purposes shall be known quantitatively to those who select them.

It is to make this work of the testing engineer more effective, to guard the lives and the interests of the public the better that this association exists. It is an open court in which the public sits in judgment on the various methods of testing. Of that public certain parts are here represented directly by their own engineers. This is true of the great railroads, the great shipbuilding and bridge builders, and the great engineering houses. Other parts of the public are represented indirectly by the middlemen or by the public engineers of tests.

The results of experience in all lands, in all climates, and under all conditions, and the points of view of all races, are here focussed in the most searching criticism of the various methods of testing, to the end that the buyer may gage their fitness with full knowledge, and thus may select intelligently those which give the fullest protection first to himself and ultimately to the public. If one method is unduly favorable to one manufacturer or to the manufacturers of one region or of one country by tending to gloss over the shortcomings of their product and to give undue prominence to its special merits, the public is here warned of the deceptiveness of that test by the evidence offered by the competing manufacturers.

However far distant may be the political "Parliament of man," which is "coming yet for a' that," the industrial parliament of man is already here. The buyer in each country may well say "My country is the world, my countrymen are all mankind," for wherever his abode he selects the fittest goods, quality and cost considered, without regard to their origin. While he is selecting his purchases, friendship, patriotism, national boundaries, empires, and continents cease to exist. [illegible] [illegible] the business of testing, [illegible] in comparing the market-place's competing goods.

[illegible] methods of testing throughout the world, to the end that the [illegible]

lative merits of all competing materials of a given kind, from whatever country they may come. The day has passed when the buyer's ignorance, his inability to ascertain for himself the fitness of what is offered him, forced him to rely on the reputation and on the assurances of the manufacturer or exporter. To-day he relies not on the untested assertions of the seller, however creditable, but on his own tests, or on tests made by his own agents. Purchase is no longer a matter of faith but one of knowledge. It is our mission and privilege to carry this substitution of knowledge for faith ever farther and farther.

Turning our attention now in a different direction and asking what our attitude ought to be toward attempts to replace or supplement our present methods of testing with new methods, we find that, though we have good reason to be dissatisfied with out present methods, yet we should be extremely cautious in the industrial adoption of new ones. Let us consider these two aspects briefly.

For every structure there are certain conditions which are more trying to it than all other conditions, certain conditions which it fulfills with the greatest difficulty. Its ability to meet these most trying conditions is the measure of its industrial and commercial fitness, usefulness, and hence value. The fact that I cannot lay my hand with certainty on these conditions does not affect the truth of this proposition. We may not know these conditions to-day, but they are intrinsically discoverable. The supreme danger to the chimney may be the gale. The supreme danger to the rail may be the unduly rapid impact of an ill-balanced driving wheel when the ground is frozen hard, and after the head of the rail itself has been brought from its initial ductility to the vitreous state by the peening of the wheels. The supreme danger to the hull plate may be dynamic stress along the rivet holes in a collision. That which at last breaks down the well aligned factory shaft may be the inevitable slight variations of stress. In each case there are probably two or more supremely trying sets of conditions; but be they few or be they many, be they recognized or be they still undiscovered, there must in the nature of the case be such most trying conditions, the ability to endure which necessarily carries along with it the ability to endure all of the other conditions of use. It is to these most trying conditions that our tests should address themselves.

We assume reasonably that the ability to meet these most trying conditions will be measured most trustworthily by that test which reproduces these same conditions the most closely. For instance, in the many cases in which the most trying stresses are dynamic, it is reasonable to believe that a dynamic test is fitter than a static one. Of course we should not leap to the conclusion that any and every dynamic test is here fitter than any and every static test.

Here, then, is one direction in which most of our tests are very faulty. Their conditions are radically unlike the most trying ones of service. The light which they throw on the fitness of the object for its proposed service is most indirect. In that respect they are unfit tests.

An objection from a wholly different direction lies against most of our tests, the objection that, because they are tests to destruction, they cannot in their nature be applied directly to the object whose fitness they would gage, but instead they must be applied vicariously to small pieces assumed to represent those objects. We do not test the individual [illegible], boiler plate, shaft, bridge post, or [illegible] on whose fitness the lives of our fellows hang, but small pieces cut from them, or for some other reason assumed to represent them. In certain rare cases we do indeed test, not merely a small fragment, but a similar whole structure, a like beam or shaft or post. This is not as bad as measuring the endurance of your recruits by finding what forced march suffices to kill their brothers, but it is open to the same kind of objection, the objection that because it is destructive it must needs be vicarious.

---

*Abstract of address delivered in New York [illegible]

†Acting President International Association for Testing Materials; Professor of Metallurgy, Columbia University, New York City.

But a great range and variety of indestructive tests suggest themselves, tests which leave no more effect on the piece tested than seeing, tasting, or smelling it would. The presence of cavities may be detected through the density: and that of plastic deformation through the potential. Microscopic examination is already well advanced. Magnetic testing has received much attention; and the electrical disintegration is now pointed out as a means of test. The number of physical properties which offer themselves as possible means of testing is very great.

Here we note that Miers and Isaac determine the supersolubility curve of solutions by measuring their index of refraction of light, and that Hönigsberg and Coker study the lines of stress by the behavior of polarized light passed through transparent specimens. What do these things mean? They mean that light, a manifestation of energy, in crossing these bodies undergoes a change; and the nature of that change teaches us concerning properties in those crossed bodies little related to light; or in short the action of the body tested upon a form of energy passed through it or reflected from it may be made to disclose and to gage properties of that body but little related to that form of energy, and with no residual effect on the body itself.

But light is only one of a considerable number of forms of energy which seem open to such use. Sound, electricity, the divers kinds of radiations which only lately disclose themselves to our amazement, and the many yet undreamed ones awaiting discovery, these are forms of energy some of which may be harnessable to a like use.

Let us remember that later our analysis of these subtler manifestations of energy will be even fuller than our present analysis of the coarse radiations of sound. As to-day we know not only the pitch and volume, but the timbre, overtones, and harmonics of sound, so later shall we know corresponding characteristics and phenomena of these other kinds of radiation, so that we seem embarrassed by the riches of the variety of agencies from which the testing engineer of an age less crude than ours may choose.

Here lies the suggestion that we may learn the properties of the very rails and girders which we are to use, and later the properties of assembled structures themselves, such as boilers and bridge posts, and conceivably in the far, far future the assembled hull, by their action and re-action with some form of energy. Who shall say that the pitch or volume or timbre of sound emitted by a rail as the result of a given excitement may not be made to disclose pitilessly its hidden defects and to measure the fitness, not alone of the material of which it is composed, but of the rail as a whole structure? Or giving rein to our fancy we hear the inspector report, "This one-hundred story building indeed responds to G sharp, but its timbre has this abnormality and these harmonics are exaggerated."

These indestructive methods indeed have the defect of being indirect in one respect to weigh against their advantage of being direct in another; they are indirect in that they gage the properties actually needed in service by means of other properties; they are direct in that they may be applied to the very objects to be used, instead of vicariously to coupons or like objects to be destroyed in the test itself.

Their natural service seems to be to supplement the vicarious destructive tests. Thus the tester of the future may prove his material by the vicarious destructive tests of coupons, and prove his structures themselves by these indestructive tests.

Having thus considered the purposes of our society, let us turn to some tangible evidence of the progress made in accomplishing them since our last congress. First, four additional countries are represented in our Council—Japan, China, Canada and Brazil, by Messrs. Saito, Kwong, Hersey and di Paolo—bringing the number of countries represented on the Council up to 25. Second, our membership has increased from 2,160 to 2,680, or by 24%, and now represents 30 countries, and every continent. Adding the members for the present Congress year, our membership becomes about 3,700. Third, in addition to the existing national societies closely affiliated with us in Germany, America, Italy, Austria, and Hungary, two new national societies have arisen in Russia; and in addition to the existing organization of our own members into a racial group in France and Belgium, a like national Swiss group has formed. I appeal to the members of Council from other countries to institute like works. Perhaps by this means better than by any other can they discharge that solemn trust which they accepted in entering the Council.

That we are recognized not as a private club for our own benefit and enlightenment but primarily and essentially as a benevolent institution, successfully aiming to benefit mankind; an institution to which our contributions of time and thought are such as no sordid motive could evoke, is shown by the generous and widespread response to our appeal for aid in this work, and by the action of many governments and important public bodies in appointing representatives on our commissions.

Here it may be mentioned that the volume of papers for this congress is about twice as large as that of any previous congress.

The Council contemplates ways of lessening the impediments to the efficiency of our international committees, due both to the language difficulties and to the usual need of carrying on their deliberations by correspondence instead of face to face.

The immediate purpose before the founders of our society was to perfect and unify the methods of testing; the ultimate purpose was to enable the public to get fit goods. But if I am to learn whether my purchase is fit by testing it, I must know not only how to test it, i.e., how to measure its properties, but also how much of each property it ought to have. Of what use is a process for testing axles by impact or tension unless I know quantitatively what tensile properties they ought to have and what impact they ought to endure? Of what use are methods of testing without reception specifications? One is the necessary complement of the other.

It so happens that, in building a society fitted for the immediate end of improving methods of testing, we have simultaneously fitted it for the indispensible supplement, specification making. In bringing together those competent to improve methods of test we have also brought together those most competent to draw specifications. We have "builded better than we knew." We have unconsciously made an organization fitted for filling both needs of the public, for telling it both what properties, quantitatively, its purchases need and also how to measure those properties.

I am not unmindful of the obstacles and pitfalls in the way of specification making. I understand the gravity of the commercial questions involved. I see that commercial interests may readily be antagonized into the positon of resenting supposed interference. But let us look at obstacles as things primarily to be overcome and pitfalls as things primarily to be bridged, remembering that where there is a will there is a way; that the human beings with commercial interests on other continents do not differ in their innermost nature from the corresponding human beings on this continent; and that if it has proved possible to bring maker and user into harmonious and indeed enthusiastic coöperation here it ought to be possible there.

As men of your sagacity are ever anxious to profit by the experience of others, I commend most earnestly to your attention this opportunity which your American visit offers to profit by the special experience of the American Society for Testing Materials, which stands to you in a relation of filial affection and pride. The natural development of the American Society has happened to be in the direction of specification making. In our opinion, based on our now very considerable experience, this work has proved far more valuable, and of far greater profit to the public, than our simultaneous work of perfecting methods of measurement. Your visit here gives you an opportunity of judging the truth of this opinion, and, in case it shall seem to you true, the further opportunity of profiting by our experience in the methods to be followed and those to be avoided in this special work. Not less strongly do I commend to our American members this opportunity to learn from their foreign colleagues the work which they have found most useful, and the means which they have found most effective.

In closing this address I ask the members of the committee who have labored so zealously and so wisely to organize and carry out this congress and its excursions to rise and receive the thanks which, on behalf of the association, I give them from the bottom of my heart, and I ask their chairmen, Messrs. Clark, Holmes, Humphrey, Hunt, Marburg, Moldenke and Schmitt, and the officers of the subcommittees, Messrs. Chapman, Dunning, Hamburger, Kinkead, Kunz, Miller, Moisseiff, Stoughton and Wight, to express our gratitude to the absent members of their committees. Our warmest thanks are due also to our indefatigable secretaries, General Secretary Reitler and Secretary Porter, for their most zealous and efficient labors.

Ladies and gentlemen, I have sought to impress on you that we are among the guardians of mankind; that our services to humanity are of so high a nature as to stimulate us to seek earnestly how we may make them more effective and wider; that one means is to supplement and in time replace our present methods, which rightly viewed are but temporary expedients, with better ones; but that this replacement, much as it is needed, should be made with extreme caution. Classing the two kinds of testing into the vicarious tests to destruction on the one hand and on the other hand the indestructive tests applied directly to the objects which are to enter into service, I have pointed out that in the future these two classes of tests may well be used to supplement each other; that the vicarious tests should be made to reproduce as closely as possible the most trying conditions of service, and that the indestructive tests, with which we have hardly made even a beginning, hold out very [illegible] I have touched on our competence and our consequent duty to add specification making to our original plan and thereby to increase very greatly our services to our fellows, and through our fellows to our [illegible] Here are tasks which may well be [illegible] of the International Association for Testing Materials.

* * *

STORM AND SURFACE WATER DRAINAGE IN RELATION TO SEWAGE DISPOSAL.

The following is an extract of a paper read by Mr. [illegible] R. Knight, C.E., at the second annual Congress of the Canadian Public Health Association at Toronto.

Storm water, which is the subject [illegible] of the paper, is defined as that portion of the rainfall which finds its way into the sewers. It is described as [illegible] offensive and [illegible], carrying [illegible] of all kinds and street [illegible] and matters flushed out of the sewers. Storm water is to all intents and purposes diluted sewage.

Under the heading Rainfall, it is pointed out that extraordinary storms (those above one inch per hour) need only be considered in making calculations. Averages are not to be considered. A probable maximum rainfall should be decided upon.

The next consideration is that of the characteristics of the drainage areas. Some interesting figures are given, showing the proportions of impervious areas for different classes of property in Toronto. These proportions range from 0.19 to 0.75, and were arrived at in connection with the author's work on the design of the storm overflow sewers of Toronto.

The quantity of storm water from drainage areas receives attention, and an example giving an idea of the immense amount of storm water a heavy rainstorm will produce is given.

In dealing with the characteristics of storm or surface water, the report of the Royal Commission is quoted. The first flush of storm water is conceded to be of such a foul nature that it ought to be purified. As to what is to be considered the first flush, the author suggests that the first three minutes of a storm be so taken. The difficulty of selecting the first flush, due to the time occupied in the passage of the storm water from the surface and along the sewers to the outfall is pointed out. The engineer has, therefore, to provide for the treatment of what he considers would be classified as polluting liquid.

The choice of separate or combined system, with special reference to purification, is next treated with. From the point of view of purification of the storm water the separate system is favored. In this system the storm water, while being a polluting liquid, is not so much in the nature of a diluted sewage. The difficulties of our larger cities are mentioned, the combined systems in vogue hampering the sewage disposal question considerably.

In comparing the two systems in regard to disposal, the combined system is shown to require sedimentation tanks and filters for at least three times the dry weather flow, whereas in the separate system only one and a half times the dry weather flow need be settled and filtered in the sewage works as distinct from the storm water works.

The closing chapter on purification includes an extract from the report of the Royal Commission in support of the argument for the provision of stand-by tanks for storm water. The period of settling for storm water is suggested as from one to two hours, and provision should be made to accommodate all the storm water which would be brought down to the works by the sewers due to a heavy storm during the first three minutes of the storm, allowance being made for the time occupied in the conveyance of the storm water from outlying districts to the works.

Several stand-by tanks, located in suitable positions with respect to the natural drainage of the area, are recommended. All storm water should pass through the tanks; direct currents should be avoided, however, and to meet this the author suggests the provision of long overflow or discharge weirs at the inlet and outlet. Square tanks are also recommended.

After the period of settling is over, the storm water left in the tanks should be passed on to filter beds at a slow rate through sprinklers or other such method.

In conclusion, it is pointed out that the report of the Royal Commission cannot be applied strictly to Canadian needs. In the majority of cases we have to empty our sewage and storm water into rivers or lakes, which have to form our source for supply of drinking water. Not so in England. The aims of the Commission were directed towards the prevention of sludge deposits and nuisance in the rivers and lakes. With the question of pollution as it is presented in Canada, it is time that some steps were taken to prevent this form of contamination of our water supplies, in the manner pointed out by the author, in the provision of stand-by tanks and filters for the first flush due to heavy storms.

A few remarks in reference to the works at present being carried out in Regina and Toronto bring this paper to a close.

◆

QUEBEC RAILWAY, LIGHT, HEAT AND POWER COMPANY

The annual meeting of the Quebec Railway, Light, Heat and Power Company was held on Tuesday, and save for the presentation of the financial report showing the result of the year's operations, the street is but little wiser as to the many points of recent discussion.

It is satisfactory to note that the earnings of the company for the year ending June 30th, 1912, were equal to 2.11% on the common stock, after all charges, save dividends, had been provided for. This meant that had no dividends been paid, the surplus for the year would have amounted to $211,200. Inasmuch, however, as two quarterly dividends of 1% each, making a total of $199,990 were paid during the year, the total surplus brought forward from the year's operations was but $11,210.

This compared with the deficit of $37,381 the previous year. This comparison is a fair one, inasmuch as the dividends paid the previous year were exactly the same as those of the last year. The fixed charges of the past year, however, were $204,000 more than the previous year, while the amount written off to organizing expenses was $7,000 less this year than a year ago.

Those who attended the meeting in the hope that light would be shed upon the situation as respects the relationship between the Quebec Railway and the Quebec and Saguenay were disappointed. A representative of the Paris interests was present and asked certain questions with respect to expenditures on the Quebec and Saguenay which were refused, although Sir Rodolphe added that the affairs of the company would presently be straightened out. The following is a comparison between the profit and loss statements of the past two years:

	1911.	1912.
Gross	$1,280,127	$1,415,825
Operating expenses	661,907	734,925
Net earnings	$ 618,220	$ 680,900
Sundry interest earned	11,109	....
Miscellaneous earnings	....	194,584
Gross income	$ 629,319	$ 875,484
Fixed charges	456,329	660,364
Net income	$ 172,990	$ 215,120
Dividends 2 quarters	199,990	199,990
Org. expense	10,681	3,910
	$ 210,671	$ 203,900
Deficit on 1911 oper.	$ 37,681	....
Surplus on 1912	....	$ 11,211
Brought forward from previous year	100,000	62,328
Total surplus at June 30th	$ 63,319	$ 72,539

The accuracy of the statement was sufficiently vouched for by the auditors and the only criticisms that were heard among the shareholders were as to whether sufficient appropriations for various purposes had been made, and what effect would be on the percentage of surplus to capital, were it necessary to make allowance for depreciation, &c.

The statement of assets and liabilities and of the progress made by the company, in the matter of traffic, was as follows. The point in this which perhaps is of greatest interest is the excess of payments now due, or falling due, over available funds.

Assets.

Investments, stocks, bonds and interests in other corporations	$22,819,192.64	
Less bonds or subsidiary companies outstanding	3,659,000.00	
		$19,160,192.64
Treasury bonds		1,286,100.00
Advanced to controlled companies for construction		865,359.36
General construction		389,952.73
Underlying Securities Redemption Fund		40,169.75
Cash on hand and in banks		254,513.25
Accounts and bills receivable		241,643.01
Stores and supplies on hand		136,739.87
		$22,374,670.61

Liabilities.

Capital stock		$10,000,000.00	
Less unissued		500.00	
			$ 9,999,500.00
Bonds		$14,600,000.00	
Less in escrow to redeem bonds of subsidiary companies	$3,659,000		
Less unissued	220,600		
Less cancelled	114,000		
		$ 3,993,600.00	
			$10,606,400.00
Accounts payable			158,572.62
Sundry loans			1,171,968.01
Accrued interest			148,875.12
Unpaid interest and dividends			189,586.84
Accrued charges			8,154.10
Reserves			18,074.47
Surplus			73,539.45
			$22,374,670.61

Passengers carried in the city division: 1909, 6,859,679 includes tercentenary celebration); 1912, 8,785,995.

Passengers carried on the Montmorency division: 1909, 1,442,327 (including tercentenary celebration); 1912, 1,581,846.

Gross gas output from January, 1905, to September 1, 1912: 1909, 122,000,000 cubic feet 50 cent gas for 6 months; 1910, 98,000,000; 1911, 103,000,000; 1912, 74,000,000 (8 months).

The number of directors were reduced to nine from fifteen and the following were appointed:—Sir Rodolphe Forget, Hon. Senator J. P. B. Casgrain, Hon. Robert MacKay, Messrs. J. N. Greenshields, Lorne C. Webster, Paul Galibert, D. O. Lesperance, L. C. Marcoux and O. B. d'Aoust. Of these, the new names are the last three. The directors whose names are absent are as follows: Hon. C. E. Dubord, A. Haig Sims, W. G. Ross, Maxime Beauvisage, Anthony Thierree, Louis Galliard and Charles Michel.

Sir Rodolphe Forget suggested the appointment of a president who would reside in Quebec, who could give his whole time and attention to the affairs of the company, but he was appointed president at a meeting of the directors held after the shareholders' meeting, and it is thought will continue to occupy the office until other arrangements can be made.

AMERICAN ROAD-BUILDERS' ASSOCIATION CONVENTION.

Highway improvement, one of the most vital questions before the United States, will engage the attention of the foremost public officials and expert road builders in the country during the four days of the ninth annual convention of the American Road Builders' Association, at Music Hall, Cincinnati, Ohio, December 3 to 6. Those in charge of the arrangements have been busy with the plans for the meeting, and the exhibition of road building materials and machinery to be held in conjunction with the convention, for several months, and although there yet remains nearly three months before the first session will be opened, the number of official delegates already appointed and the amount of space taken by exhibitors make it beyond question that the convention will be not only the principal event of the year in road building circles, as it has been each year for nearly a decade, but will also surpass all previous meetings of the association.

Governor Judson Harmon, of Ohio, has evinced his interest and his sympathy with the efforts of the American Road Builders' Association to the extent of addressing letters to the governors of all of the other States, strongly endorsing the purposes for which the meeting has been called and requesting the appointment of official delegates. Although this letter was sent out only a short time ago, and although some of the chief executives to whom the letter was addressed were absent from their States, delegates have been appointed by Governor O'Neal, of Alabama; Governor Deneen, of Illinois; Governor Oddie, of Nevada; Governor McDonald, of New Mexico; Governor Burke, of North Dakota; Governor Colquitt, of Texas, and Governor Mann, of Virginia. Governor Brown, of Georgia, has signified his intention of complying with the request, and Governor Foss, of Massachusetts, Governor Cruse, of Oklahoma, and Governor Aldrich, of Nebraska, have taken steps to name delegates.

The American Road Builders' Association has held conventions of constantly increasing size and importance during the past nine years, and is composed chiefly of state, county, town and city officials; engineers engaged either as public officers or in private practice in the construction and maintenance of roads and streets; road and street contractors; consulting engineers and chemists, and others to whom the building and up-keep of country roads and city streets is of direct and vital interest. It is the only national organization of the United States which limits its annual convention to the consideration of the administrative and technical phases of road and street construction, and it numbers in [illegible] known among road builders and highway officials.

Although the formal sessions of the convention are limited to the consideration of the particular questions in which its members are interested, there is always much of popular interest at its meetings. This is especially true of [illegible] which are held in conjunction with the convention. This plan was inaugurated by the association at its sixth annual [illegible] r will include not only all the features [illegible] departure from the usual plan has been contemplated by the association since its 1911 convention, and the manner in which the States and cities have taken hold of the matter gives promise of a most interesting display. The commercial exhibits, as in former years, will include displays by the leading manufacturers of road machinery, manufacturers of and dealers in various materials, including oils, asphalts, tars, cements, etc., paving companies and others.

The meetings and the exhibits will all be held in Music Hall, which is conveniently situated, and provides ample accommodations. The city officials and citizens of Cincinnati, as well as the State officials of Ohio, are co-operating with the American Road Builders' Association and putting forth every effort to make the 1912 convention the most successful ever held.

Nelson P. Lewis, chief engineer of the Board of Estimate and Apportionment of New York city, is the president of the American Road Builders' Association; Harold Parker, ex-chairman of the Massachusetts State Highway Commission, first vice-president; W. W. Crosby, consulting engineer of the Maryland State Highway Commission, treasurer, and E. L. Powers, editor of "Good Roads," secretary.

THE CANADIAN FORESTRY ASSOCIATION CONVENTION.

The Canadian Forestry Association held their annual convention in Victoria, B.C., September 4th to 6th, with Mr. John Hendry, of Vancouver, the president, in the chair.

In the course of his presidential address Mr. Hendry said:

"To keep 'fake' settlers out of areas suited principally for timber requires, first, a knowledge of the country, which will show where such areas are, and the power in the various governments to resist political pressure brought to bear upon them to allow pretended settlers to locate on what is chiefly valuable as timber land. Surveys should, therefore, be made as rapidly as possible to ascertain the areas of absolutely forest land, and the whole forest staff should be free from any partisan influence, so that it will not be silent when measures antagonistic to the good of the forest are proposed, or when parties endeavor wrongfully to enter upon forest lands. To obtain the best results, the forest service should be placed under civil service regulations, whereby appointments, promotions and dismissals will be made solely upon merit. It is gratifying to know that British Columbia is taking a forward stand in these matters and that a forest service is now being organized which bids fair to be the finest in the Dominion. This means the expenditure of a large amount of money, but, so long as the service carries out the idea of protecting our forests, with an eye single to the public interest, I am sure the government will be sustained by the people in this work."

The Minister of Lands, Hon. W. R. Ross, gave a paper on "The [illegible] of the Forest Wealth of British Columbia." Sir Richard McBride, the Premier, he said, had made it plain that this province, so far as the others are concerned, proposes to take the lead in matters affecting the modern policy of conservation of forests. It was particularly fitting that the present convention should be held in Victoria, as it gave British Columbia an opportunity to give firsthand notice to its friends from other provinces that [illegible] expect that for the latest word in forestry conservation all must come here.

Mr. Ross in his paper, traced briefly but concisely what has been done in British Columbia for the protection of the [illegible] and explained fully the composition and working of the [illegible] of his department, starting his review from the appointment of the forestry commission, the work of which he praised highly.

The resolutions committee named by the president is composed of Hon. W. R. Ross, Mr. R. H. Campbell, Dominion forester; Dr. Fernow, dean of the School of Forestry, of Toronto University; Mr. Aubrey White, Deputy Minister of Lands, Forests and Mines of Ontario; Mr. Wm. McNeill, Vancouver, and Mr. A. C. Flumerfelt, Victoria.

Resolutions were adopted without discussion congratulating the Government of British Columbia upon the excellent beginning it had made in forest conservation, endorsing a suggestion made by the British Columbia Lumber and Shingle Manufacturers' Association that a course in logging engineering should be established at the University of British Columbia; reiterating its former pronouncement that all appointments in the forest services of the Dominion and provinces should be based on ability and experience; that squatting or settlement should not be allowed on lands that are chiefly valuable for timber; that the fire acts of the three prairie provinces be revised so as to provide more efficiently for the prevention of fire; urging upon the Dominion and Provincial Governments the advisability of adopting measures as soon as practicable of disposing of logging debris; recognizing the work of the United States foresters and hoping for increasing co-operation between the two countries; besides the usual formal resolutions of thanks to Lieutenant-Governor Paterson, Sir Richard McBride and colleagues and others who have shown the visitors and members courtesies.

The fact was referred to several times that practically all the young men now engaged as trained foresters in Canada have been pupils of Dr. Fernow, dean of the School of Forestry in the University of Toronto.

A MUNICIPAL OPERA HOUSE.

A municipal opera house at San Francisco, California, is projected. The building will be erected from private funds raised by the Musical Association of San Francisco. The estimated cost is $650,000. The building will stand on land owned by the city and would form a part of the new civic centre, becoming the property of the city after its completion. The management of the building, it is stated, would be vested in 15 trustees, to be chosen by the city of San Francisco, the Musical Association, the University of California and Stanford University. It is stated that between $400,000 and $500,000 toward the cost of the building has already been pledged.

CANADIAN SOCIETY OF CIVIL ENGINEERS' (TORONTO BRANCH) EXCURSION.

The following arrangements have been made for the excursion of the Toronto branch of the Canadian Society of Civil Engineers:

Leaving Toronto on Friday, September 20th, at 5 p.m., in a special car on the regular train of the Canadian Pacific Railway, the party will arrive in Bobcaygeon about 8 p.m., where supper, sleeping accommodation and breakfast the next morning will be arranged for.

Early Saturday morning, by the courtesy of Mr. Jos. H. McClellan, superintendent of the Trent Canal, the party will proceed by boat up the Trent Canal to Lake Simcoe. On the way, some time will be spent examining the Kirkfield lift lock. Lunch will most likely be had at Beaverton.

The return journey will be made either by the Canadian Northern Railway from Beaverton of by the Toronto and York Radial from Jackson's Point.

PERSONAL.

MR. J. L. WOOD, formerly of Peterborough, and MR. GEORGE SERVICE, construction engineer, of Toronto, have entered into partnership in the city of Toronto as construction engineers.

MR. W. H. BELL, of the well-known English engineering firm, Sir W. G. Armstrong Whitworth & Company, Limited, is in Toronto for a few days conferring with the management of the Canadian British Engineering Company, Limited, who have been appointed Canadian agents for his firm.

MR. WALTER B. SNOW, publicity engineer, 170 Summer Street, Boston, Mass., has added to his staff Mr. Chester R. Ross, who will act as manager of the addressing and mailing department. Mr. Ross brings to this position an extended experience covering three years with the Griffin Wheel Company, four years with the Boston Transcript, and a considerable period as salesman in various lines of industry.

MR. ALMAN HARE, president and managing director of the Hare Engineering Company, Limited, 14-16 King Street East, Toronto, is arranging to begin immediate construction on their new works at Galt, Ontario. Mr. Hare has just returned from England where he has been for the last three months arranging for the financing of the company. The English syndicate have underwritten the unissued preference shares of the company amounting to $150,000, so that immediate construction of the work will be begun. The property at Galt is about six acres in extent and the company will manufacture power plant equipment and special machinery. Sir Ernest Shackleton, C.V.O. "late of the South Pole," has been elected as chairman of the London board and Mr. A. Cairn-Hodge, M.I.C.E., F.R.G.S., has also been placed on the board.

MR. ROBERT F. PACK, formerly general manager of the Toronto Electric Company, Toronto, Canada, has been appointed general manager of the Minneapolis General Electric Company. He assumed office Tuesday, September 10th. Since the resignation of Mr. A. W. Leonard early in August, the position has been temporarily filled by Mr. Samuel Kahn, who will resume his duties in the operating department of H. M. Byllesby & Company. General George H. Harries, vice-president of the Consumers Power Company, will continue to act in the supervisory capacity over all the properties of this corporation, Mr. Pack being in direct charge of the Minneapolis property. Mr. Pack was born in England in 1874. He was educated for the British navy, but came with his parents to Canada at an early age. Twenty-one years ago he entered the service of the Toronto Electric Light Company as an office boy. At that time the lighting supplied in Toronto consisted of open series arc lamps. Mr. Pack advanced steadily through the positions of accountant, comptroller, secretary and finally general manager of one of the largest of the Canadian electric companies, serving a population of about 450,000. He is ranked among the most progressive of utility managers. Mr. Pack is president of the Canadian Electrical Association and as such is also a member of the executive committee of the National Electric Light Association and has also served upon various committees. He is also a member of the American Institute of Electrical Engineers, and a member of the following clubs: Engineers' Club, of New York; Engineers' Club, of Toronto; Royal Canadian Yacht Club, Arts and Letters Club, and Albany Club, all of Toronto. He was a member of the Publicity Committee of the Toronto Board of Trade.

LESLIE R. THOMSON, B.A., Sc., lecturer in civil engineering at the University of Manitoba, has resigned to accept a position with the Dominion Bridge Company, at Montreal.

MR. W. T. BATHO, managing director of the Consolidated Diesel Engine Manufacturers, Limited, England, called at *The Canadian Engineer* office this week. Mr. Batho expects to go to the coast before returning to the Old Country.

COMING MEETINGS.

AMERICAN ROAD CONGRESS.—First Annual Session to be held in Atlantic City, N.J., at the Million Dollar Pier, September 30th to October 5th, 1912. Secretary, J. E. Pennybocker, Colorado Bldg., Washington, D.C.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE CANADIAN HIGHWAY ASSOCIATION.—Meeting will be held in Winnipeg, Man., October 9th to 12th. Secretary, P. W. Luce, Room 4, Cunningham Block, New Westminster, B.C.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Power, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W. Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the [illegible]

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 409 Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible]

[illegible] BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-Jack. Meets every first and third Friday of each month, October to April, in [illegible]

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Mayor Lees, Hamilton; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

[illegible] ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy-Treasurer, E. Hingley, [illegible]

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon [illegible]

THE [illegible] OF CANADIAN MUNICIPALITIES.—President, [illegible] W. D. Lighthall, K.C. [illegible]

THE [illegible] OF NEW BRUNSWICK MUNICIPALITIES.—President, [illegible] J. W. McCready, City [illegible]

[illegible] MUNICIPALITIES.—President, Mr. A. S. [illegible] Secretary, A. Roberts, Bridgewater, N.S.

[illegible] MUNICIPALITIES.—President, Mayor [illegible] Moose Jaw [illegible]

[illegible] MUNICIPALITIES.—President, Mayor [illegible] Mr. H. Bose, Surrey [illegible]

[illegible] MUNICIPALITIES.—President, Mayor Mitchell, [illegible] Alta.

[illegible] MUNICIPALITIES.—President, Reeve Forke, [illegible] Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President E. T Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE. Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto. Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5 Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Fairhaven, N.B.—Tenders for the construction of a pierhead to the public wharf at Fairhaven, Deer Island, Charlotte County, N.B., will be received by R. C. Desrochers, secretary, Department of Public Works, Ottawa, until October 8th, 1912. Plans, etc., can be obtained at this department, and at the offices of F. G. Goodspeed, Esq., district engineer, St. John, N.B.; Geoffrey Stead, Esq., district engineer, Chatham, N.B., and on application to the postmaster at Fairhaven, N.B.

Fernie, B.C.—Tenders addressed to the director of contracts, Department of Militia and Defence, Ottawa, will be received until noon of Sept. 21st, 1912, for the construction of a new drill hall at Fernie, B.C. Specifications may be seen and full particulars obtained at the office of the district officer commanding military district No. 11, Victoria, B.C., the office of the town clerk, Fernie, B.C., officer commanding "A" Company, Kootenay Rifles, Fernie, B.C., and the director of engineer services, headquarters, Ottawa.

Holberg, B.C.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until Sept. 30, 1912, for the construction of a pile wharf and pile bent approach at Holberg district of Comox-Atlin, B.C. Plans, specifications and form of contract can be seen and forms of tender obtained at this department and at the offices of C. C. Worsfold, Esq., district engineer, New Westminster, B.C., and on application to the postmaster at Holberg, B.C.

Goderich, Ont.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until October 10, 1912, for the construction of part of the river breakwater at Goderich, Ont. Plans, specification and form of contract can be seen and forms of tender obtained at this department and at the offices of H. J. Lamb, Esq., district engineer, Windsor, Ont.; J. G. Sing, Esq., district engineer, Confederation Life Building, Toronto, Ont.; and on application to the postmaster at Goderich, Ont.

Kirkfield Park, Man.—Tenders for the construction of a sewer on Silver Street and Thompson Drive to the Assiniboine River in D.G.S. 12, St. James, will be received until Sept. 21st, 1912. Plans and specifications may be seen at the office of the engineer of the municipality, Municipal Hall, Kirkfield Park P.O., Man.

Lanoraie, P.Q.—Tenders for the partial reconstruction and extension to wharf at Lanoraie, Berthier County, P.Q., will be received by R. C. Desrochers, secretary, Department of Public Works, Ottawa, until October 10, 1912. Plans, specification and form of contract can be seen and forms of tender obtained at this department and at the offices of J. L. Michaud, Esq., district engineer, Merchants Bank Building, Montreal, P.Q., and on application to the postmaster at Lanoraie, P.Q.

Massett, B.C.—Tenders sent to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until October 15, 1912, for the construction of a pile wharf at Massett (white settlement), Queen Charlotte Island, Comox, Atlin district, B.C. Plans, specifications, etc., at the department and at the offices of G. B. Hull, Esq., district engineer, Prince Rupert, B.C.; C. C. Worsfold, Esq., district engineer, New Westminster, B.C., and on application to the postmaster at Massett, B.C.

New Westminster, B.C.—Tenders will be received by A. O. Powell, harbor engineer, Room 22, 26 Lorne Street, New Westminster, until noon of October 8, 1912, for a ladder dredge having a capacity of 250 cubic yards per hour and excavating to a depth of 25 feet. (See advt. in Canadian Engineer.)

Niagara Falls, Ont.—Tenders are invited for the construction of approximately 2,930 square yards of vitrified brick pavement, with concrete curbs, on Jepson Street from Victoria Avenue to Fourth Avenue. Specifications may be seen and forms of tender obtained at the office of J. C. Gardner, city engineer. Tenders to be received by the city clerk up to noon on September 21, 1912.

Niagara Falls, Ont. — Sealed proposals addressed to Blanche Carr, secretary, Board of Water Commissioners, Niagara Falls, will be received until October 1st, for the installation of new centrifugal pump. Specifications furnished on application at water works office. (See advt. in Canadian Engineer.)

North Battleford, Sask.—Tenders will be received by the secretary of the North Battleford High School Board until noon of Sept. 19, 1912, for the erection and installation of a plumbing, heating and ventilating system to be installed in the North Battleford Collegiate. Plans and specifications can be seen at the office of the architect, and at North Battleford. Hugh Maher, North Battleford, Sask.; David Webster, Kempthorne Block, Saskatoon, Sask.

Penticton, B.C.—Tenders will be received until Sept. 25th, 1912, for the erection of a concrete power station, about 35 ft. square, including the furnishing of materials as specified. Plans and specifications may be seen at the office of F. H. Latimer, municipal engineer, Penticton; at the office of Mather, Yuill & Co., consulting electrical engineers, 429 Pender Street, Vancouver, B.C., or at the Municipal Offices, Penticton, to whom tenders should be sent.

Quebec, Que.—Tenders addressed to Raoul Renault, secretary-treasurer, will be received at the Quebec Harbor Commissioners' office up to noon of October 21st, 1912, for the construction and delivery in complete order of a 1,000,000 bushel capacity grain elevator, with marine tower and shipping apparatus. Full particulars of the requirements for the elevator, etc., may be obtained by applying to the harbor engineer's office, Quebec. (See advt. in Canadian En[illegible]

Seaforth, N.S.—Tenders will be received by R. C. Desrochers, secretary, Department of Public Works, Ottawa, until October 7th, 1912, for the construction of a breakwater at Seaforth, Halifax Co., N.S. Plans, specifications and form of contract can be seen and forms of tender obtained at this department and at the offices of H. A. Russell, Esq., district engineer, Halifax, N.S.; E. G. Millidge, Esq., district engineer, Antigonish, N.S., and on application to the postmaster at Seaforth, N.S.

Saltcoats, Sask.—Tenders sent to D. C. McNab, Deputy Minister, Department of Railways, Telegraphs and Telephones, Province of Saskatchewan, will be received until Sept. 19, 1912, for the erection of a one story brick veneer telephone exchange building in Saltcoats. Plans, specifications, and all information may be obtained on application to Mr. D. C. McNab, or to Ernest Brown, architect, 108 Donahue Block, Regina.

Shutty Bench, B.C.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until September 30th, 1912, for the construction of a pile bent and timber decking wharf at Shutty Bench, district of Kootenay, B.C. Plans, specifications and form of contract can be seen and forms of tender obtained at this department and at the offices of F. W. Aylmer, Esq., district engineer, Chase, B.C.; C. C. Worsfold, Esq., district engineer, New Westminster, B.C.; and on application to the postmaster at Kaslo, B.C.

St. Pierre les Becquets, P.Q.—Tenders addressed to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until October 15th, 1912, for the construction of a wharf and approach, and dredging of berth for headblock at St. Pierre les Becquets, county of Nicolet, P.Q. Plans, specifications, etc., can be obtained at this department and at the offices of A. G. Sabourin, Esq., district engineer, Sherbrooke, P.Q.; A. R. Decary, Esq., district engineer, post office building, Quebec; F. X. Berlinquet, Esq., district engineer, Three Rivers, P.Q.; J. L. Michaud, Esq., district engineer, Merchants Bank Building, Montreal, P.Q., and on application to the postmaster at St. Pierre les Becquets, P.Q.

Toronto, Ont.—Tenders will be received addressed to the Chairman of the Board of Control, City Hall, Toronto, [illegible] for the construction of the following works:

Asphalt pavements on St. Clair Avenue, Bathurst (east [illegible]

Brick block, St. Clair Avenue, Hendrick Avenue (west [illegible]

[illegible] ed at the office of the Commissioner of Works, Toronto. G. [illegible]

Welland, Ont. [illegible]

Winnipeg, Man. [illegible]

Winnipeg, Man. [illegible]

Willow Point, B.C.—Tenders for the construction of a pile bent and timber decking wharf at Willow Point, district of Kootenay, B.C., will be received by R. C. Desrochers, secretary, Department of Public Works, Ottawa, until October 11, 1912. Plans, etc, at this department and at the offices of F. W. Aylmer, district engineer, Chase, B.C.; C. C. Worsfold, Esq., district engineer, New Westminster, B.C., and on application to the postmaster at Willow Point, B.C.

Winnipeg, Man.—Tenders for supplying the number of single adjustable school desks required by the Winnipeg Public School Board for two years from date of contract, will be received until October 3, 1912. Specifications, etc., may be had on application to J. B. Mitchell, Commissioner of Supplies, School Board Office. R. H. Smith, secretary-treasurer, W.P.S.B.

◆

CONTRACTS AWARDED.

Craik, Sask.—The contract for the erection of a town hall was awarded to Messrs. Jas. Bruce and Son, of Lumsden, Sask., for $17,635. No tenders were accepted for the skating and curling rink.

Fort William, Ont.—The Canada Iron Corporation, of Fort William, have the contract for the supply and delivery of a quantity of cast iron and lapwelded steel pipe. John Wilson, city engineer.

Moncton, N.B.—At a meeting of the Water and Light Committee it was decided to award the contract for laying the city water pipes to Messrs. Docity T. LeBlanc and Fred Bourgeois.

Montreal, Que.—Messrs. Munderloh and Co., Ltd., have obtained a large contract for supplying steel pipe, in sizes varying from 8" to 20", for Medicine Hat. Mr. R. S. Lea is consulting engineer.

Montreal, Que.—The following contracts have been awarded: Three city trucks, one at $3,500, two at $3,200, supplied by Messrs. W. E. Seagrave and Co., of Walkerville, Ont.; fire engine, $5,800, by the Waterous Engine Co., 72 Queen St. W., Toronto.

New Westminster, B.C.—Contract has been let for the foundations for the new double track bridge for the Canadian Pacific Railway over Pitt River to the Foundation Company of New York, the contract price being half a million dollars.

Toronto, Ont.—The Property Committee of the Board of Education have awarded contracts as follows:

Western Avenue School—Masonry, $9,877, James Wickett; carpenter work, $8,100, Croker and Le Drew; plastering, $1,448, George White; painting, $650, F. Palmer and Company; roof and sheet metal work, $580.25, J. T. Flowers; porous terra cotta work, $1,377, Robert Bennett.

Vancouver, B.C.—The contract for the new home for the Vancouver Club was awarded by Architects Sharp and Thompson to the Norton Griffith Steel Construction Company, who secured the job on a percentage basis. The new building will cost $250,000 when completed, and that will be only half of what the entire building will cost. Another new wing is to be erected uniform with the one that is now under construction.

◆

RAILWAYS—STEAM AND ELECTRIC.

Halifax, N.S.—A marked falling off in the receipts of the Halifax Electric Tramways Company, Ltd., for the week ending Sept. [illegible], as compared with the corresponding period of last year. The figures are as follows:

1912	1911	Decrease
[illegible]	[illegible]	[illegible]

Leaside Junction, Ont. It is reported that the Canadian Northern Railway officials will order construction work started [illegible] during the next few weeks.

London, Ont. The municipal council have practically abandoned the scheme calling for the electrification of the London and Port Stanley Railroad. Several offers to lease the line have been received.

Dolarway Pavement

"It is permanent because it is concrete."

SOLVES THE CONCRETE PAVEMENT PROBLEM

UNTIL the advent of Dolarway, the success of concrete pavements was questioned. They were perfect in theory but did not work out in practice.

A few years ago Dolarway Pavements were laid in Ann Arbor, Michigan, and the problem of satisfactory concrete pavements was solved. The solution was as simple as it is satisfactory.

Over the concrete was spread a thin layer of Dolarway bitumen. This made the ideal plastic surface, without which concrete pavements had been a failure. The surface is not only inexpensive but its renewal costs very much less than the maintenance costs of any other form of pavement.

This thin sheet of Dolarway bitumen has proven ample to protect the concrete from fracture by traffic or damage by water or frosts. In fact, as long as the bitumen is maintained the concrete shows no wear or deterioration.

The total cost of a Dolarway Pavement varies from $1.00 to a little over that sum per yard.

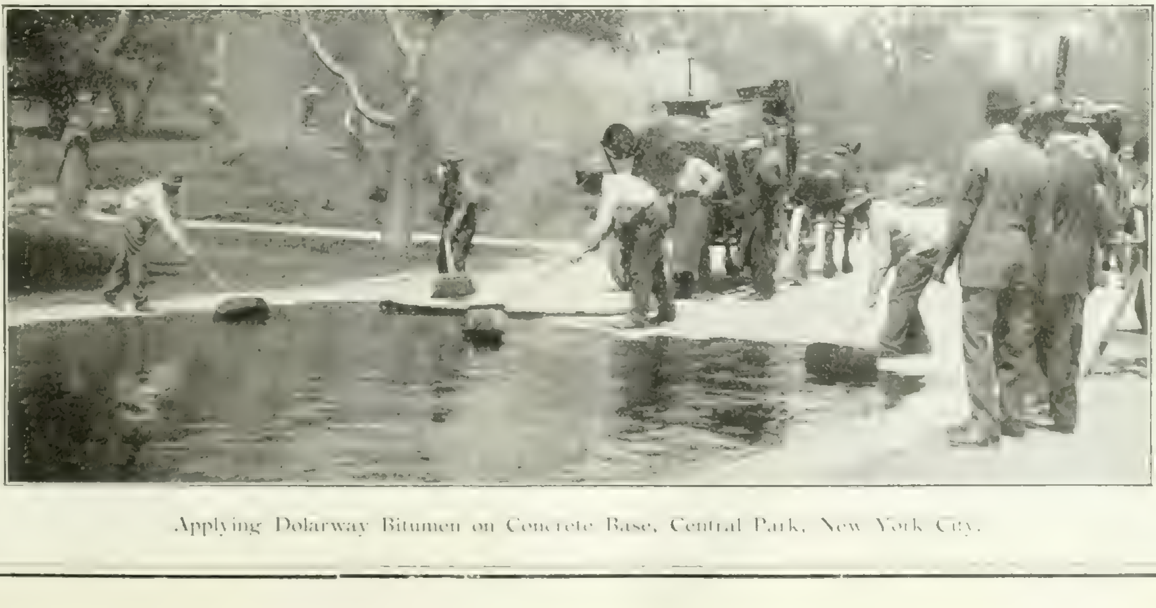
The pavement presents a handsome surface; it is quiet under traffic; no dust or mud is produced; no damage by oil drippings or thrusts of automobile wheels. It makes a most satisfactory cushion for horses which is one of the great objections to ordinary concrete pavements.

Dolarway is good enough for city streets and cheap enough for country roads.

Further details on request

DOLARWAY PAVING COMPANY

95 LIBERTY STREET, NEW YORK CITY



Applying Dolarway Bitumen on Concrete Base, Central Park, New York City.

Montreal, P.Q. — The management of the Montreal Tramways Company have recently purchased several right of ways and are planning to extend their lines in the near future.

Province of British Columbia.—Mr. Geo. A. Smith, P. L.S., of Alberni, B.C., has been awarded a contract by the Canadian Northern Railway for the survey work on the right of way of a new line to be constructed from Alberni to Cowichan Lake.

Vancouver, B.C.—The engineers of the Great Northern Railway overcame the difficulties caused by the tracks sinking in a bog as follows: The portion of the old track which sunk three feet under water in the bog was utilized as the foundation for a heavy mattress of timber held in place by piles. New rails were laid on this massive timber mattress and the rebuilt track ballasted after a row of piles had been driven to hold the ballasting material.

LIGHT, HEAT AND POWER

Elmira, Ont.—The Board of Trade of this municipality desire to obtain power from the Hydro-Electric Commissioners. If this is furnished it will be necessary to construct a transmission line for a distance of ten miles and there is a movement being made toward interesting the ratepayers of St. Jacobs in order that a transformer might be introduced at this point in the line.

Hagerville, Ont.—The ratepayers recently endorsed a by-law for the installation of power from the Hydro-Electric Commission into the town.

Latchford, Ont.—Mr. J. H. Black, chief engineer of the Northern Power Company, is in charge of a scheme to dam the Montreal River for the Ontario Government. This is the sixth attempt to successfully complete this work but the first under the superintendence of Mr. Black.

Ottawa, Ont.—The Hydro-Electric Commissioners will offer $2,000 for the price of expropriation of the Chats Falls property.

Shawinigan Falls, Ont.—A water turbine in No. 1 Station of the Shawinigan Water and Power Company's plant burst and flooded the building to a depth of ten feet.

Vancouver, B.C.—The ratepayers of Fourth Avenue have presented a petition to the municipal council in order that lighting standards may be placed in position along this street.

Winnipeg, Man.—The ratepayers endorsed a by-law giving the council power to spend $750,000 on an electric distribution system.

GARBAGE, SEWAGE AND WATER.

Bowmanville, Ont.—The council of this municipality [illegible] by-law to provide [illegible] to be paid [illegible] and sewage disposal works. John Lyle, Town Clerk.

Dunnville, Ont.—The Board of Water Commissioners [illegible] from the city of Berlin. These [illegible] of the Hydro [illegible] The well [illegible] the pump house in Dunnville.

Preston, Ont.—The council are considering the matter of laying a new sewer at a cost of $13,000. The bill calling for the construction of this work has received a reading. Mr. Homuth is the mayor of this town.

Sarnia, Ont.—The town council have asked the ratepayers to endorse a $240,000 bond issue to be expended in an attempt to secure a satisfactory water supply from Point Edward. James Turner, engineer of water works.

Winnipeg, Man.—The ratepayers voted against the Poplar Springs water scheme. This called for an expenditure of $1,800,000.

BUILDINGS AND INDUSTRIAL WORKS.

Coquitlam, B.C.—Work has commenced on the construction of a shipbuilding plant. Vessels of from 300 to 800 tons displacement are to be constructed at first, but officials of the company hope to construct larger ships in the near future.

Coquitlam, B.C.—The management of the Call Switch Company will erect a $20,000 building at this point.

Fort William, Ont.—The executive committee of the "Order of Lions" are making arrangements for the erection of a club house in this city. The cost of this work is estimated at $50,000. Mr. C. E. Chapple is president of the Order in Fort William.

Guelph, Ont.—Tenders are to be called in a few days for the erection of a malleable iron works in this city. The plans include six buildings of brick and concrete.

Moose Jaw, Sask.—The municipal council have decided to spend the sum of $10,000 on the installation of a modern fire signal system.

New Liskeard, Ont.—It is probable that the management of the Wahi Iron Works will commence the erection of a factory in this city in the near future. Mr. McEwen, manager.

Oshawa, Ont.—The management of the McLaughlin Carriage Company have taken out a permit which will allow them to enlarge their plant. The addition will be two stories high 250′ x 60′.

Owen Sound, Ont.—The ratepayers of this town voted in favor of granting a loan of $60,000 to Hugo H. Gutenkunst, of Milwaukee, U.S.A., who proposes to establish a malleable iron works at this point. The new concern is to have a capacity of 25,000 tons for a start.

Port Arthur, Ont.—The Italian Catholics will erect a church on corner of Banning and Dufferin Street. Estimated cost, $20,000. R. Halton, architect.

The Roman Catholic Separate School intends erecting a ward school on John Street, between Banning and Ontario. R. Halton, architect.

Victoria, B.C.—The engineering department of this city will have erected a new garbage wharf at a cost of $10,000.

Watrous, Sask.—Mr. W. Helgeson, representing the Perfection Fanning Mill Company, has opened negotiations with the town council regarding the erection of a factory at this point.

West Vancouver, B.C.—The council propose to erect a deep-sea ferry wharf at a cost of $[illegible],000, and will seek the opinion of the ratepayers in this matter.

Welland, Ont.—The management of the Canadian Steel Foundries Company will enlarge their plant during the next few months. The plans include a new building and a large extension in addition to considerable equipment.

Winnipeg, Man.—The ratepayers voted in favor of a public [illegible] being erected at a cost of $50,000. Col. [illegible] H. Ruttan, City Engineer.

BRIDGES, ROADS AND PAVEMENTS.

New Westminster, B.C.—The C.P.R. has submitted for the approval of the Department of Public Works, through Mr. C. C. Worsfold, the Dominion resident engineer, plans for a new bridge across the Pitt River to replace the big single track bridge now in operation. The plans have been forwarded to Ottawa and as soon as approved the work of construction will proceed.

The Canadian Engineer

An Engineering Weekly

REFUSE DISPOSAL PLANTS

Prior to preparing the report on the disposal of the refuse of Newark, N.J., the engineers who prepared that report—J. C. Hallock, deputy chief engineer of the Department of Public Works, and F. O. Runyon, consulting engineer—made personal inspection of ten disposal plants of various types in order to determine their merits from an economic and sanitary standpoint. The plants visited were those at Minneapolis, Minn., Milwaukee, Wis., Chicago, Ill., Columbus, O., Cleveland, O., Buffalo, N.Y., Rochester, N.Y., Westmount, Can., Richmond Borough, New York, City, and Scranton, Pa. The conditions found at these several cities were described in the report, which descriptions as abstracted by the Municipal Journal of New York are given below.

Minneapolis Incinerator.—Minneapolis has especially attracted the attention of sanitarians because of the fact that Commissioner of Health Dr. P. M. Hall has trained the householders to drain the garbage and wrap it in paper before depositing it in the can. The special virtue of this method of handling garbage by the householder lies in the reduction of the fly nuisance, a cleaner garbage can and the insurance of a good proportion of combustible matter, in the form of paper, for the incinerating plant. The latter point is a detriment rather than a benefit where the destructor type of plant is in use, as it prevents a proper mixture of rubbish and ashes with the garbage for the better distribution of moisture throughout the mass.

During the month of January, 1912, the city collection department composed of one inspector and 31 drivers gathered 841 loads of garbage and 2,298 loads of ashes. The capacity of the garbage wagons is 100 cubic feet each with a "struck" load, but in practice the wagons are heaped so that their actual capacity is at least 33 per cent. in excess of this figure, or approximately 5 cubic yards. The ash wagon is the common type of bottom dump wagon of about 3½ cubic yards capacity.

All wagons are supplied by the city and each driver is paid $100 per month for his services and that of his team. Each driver is assigned a district and held strictly accountable for the removal of ashes and garbage therein and is not required to work according to a schedule of hours per day. His duties consist in the maintaining of a clean district and not in the rendering of a given number of hours' work per day. He is, however, required to make at least one collection of mixed ashes and rubbish and one of garbage from each household in his district each week.

The garbage is collected in metal bodies mounted on wheels or runners according to the season and is delivered at a transfer station about one mile from the centre of the business district, which is also the approximate centre of population. The mixed ashes and rubbish are carted to the low lying spots of the city, whether these be streets or vacant lots. The commissioner of health believes that within a few years there will be no more available dumping grounds within the city and that when this time is reached some other method of ash and rubbish disposal must be found.

The city ordinance authorizing and directing the commissioner of health to collect and dispose of garbage throughout the city and to take charge of and operate the city's crematory says in part "that the commissioner of health, in his discretion, may require the owners and proprietors of hotels, boarding houses, restaurants, commission houses, stores and markets, at their own expense, to collect and remove their own garbage and waste material and to convey the same to said garbage crematory or dispose of the same in such manner as shall be approved by the commissioner of health."

As having a bearing upon the method of collection and disposal of garbage in Minneapolis it might be noted that even here, where the householders more generally conform to the requirements for a complete separation of garbage from ashes and under the supervision of a highly efficient commissioner of health, our inspection of their largest dump disclosed a large flock of starlings feeding on all too evident garbage, proving conclusively that a perfect separation of these two classes of refuse is still to be realized.

The transfer station is on a siding of the Sault Ste Marie Railroad, where the metal bodies of the garbage vehicles are loaded by a traveling crane onto flat cars, twelve bodies to the car, with total average weight of 36 tons per car. From the transfer station the cars are taken to the incinerating plant, which is located about four miles from the centre of the business district of the city. At the plant a traveling crane picks up one body at a time and conveys same into the building, where a special motor on a crane tilts the body, discharging the contents into a hopper opening directly over an incinerator of the Decarie type. This plant was erected by the city about twelve years ago, before the organization of the Decarie Incinerator Company, but following the original designs of the inventor with modifications developed by the present commissioner of health. This type of plant is one in which the garbage is burned on an upper grate over a grate upon which coal is used in starting and at other times as may be necessary, the garbage gradually falling upon the lower grate and being there consumed.

In this plant the gases from the furnace pass over into what is commonly termed a Dutch oven, in which coal is continually burned and the function of which is to raise the temperature of the furnace gases, destroy germ life and remove noxious vapors. From this oven the gases are made to pass through a vertical fire tube boiler and thence through an induced draft equipment to the stack. The steam generated in this boiler is used for supplying a 50 kw. direct current lighting unit and for heating a medium sized workhouse, a tuberculosis hospital and a green house.

A duplicate generating plant for 200 4-ampere magnetite street lamps is now being installed in a building adjacent to the garbage plant; also a 150 h.p. water tube boiler. Such surplus steam as the garbage plant develops over and above that required by the buildings mentioned will be used by the electric plant, but the water tube boiler will be the main source of supply for the electric plant.

The garbage plant consists of two 125-ton units, but the commissioner of health informed us that its actual capacity was 300 tons per day. At the present time they are burning about 120 tons of garbage per day of 24 hours, using between two and three tons of coal per day.

The total cost of the plant was $64,000, but allowance should be made for the fact that a large portion of the labor was supplied by inmates of the workhouse.

The cost for collection of ashes, rubbish and garbage is $1.31 per ton. The cost of disposal of garbage is $0.78 per ton, which is reduced to a net cost of $0.56 per ton by crediting plant with the heat and light furnished to the city institutions before mentioned at the rate of 6 mills per h.p. for heat and 2 cents per kw. hour for light.

Milwaukee Destructor.—The records of the cost of operation of the destructor plant are not in such condition as to warrant their use as a basis for comparison, but from the 1911 data available in the office of the director of public works we found the average cost per ton of the destruction of the garbage to be $1.44 and the cost of mixed garbage and ashes to be $0.99 per ton. This includes the cost of 400 tons of coal used during five months of the year when the percentage of green garbage was high and it was necessary to use additional fuel.

These figures should not, in justice to the plant, be accepted, for the reason that the number of employees at the present time is far in excess of the actual requirements. From our inspection we are convinced that it would be properly and sufficiently manned with two-thirds the force employed at present.

The condition of the plant is excellent, the garbage is destroyed at temperatures between 1,400 degrees and 1,800 degrees Fahr., without odor, and all of the power used about the plant is obtained from steam generated by it in boilers through which the furnace gases pass on their way to stack.

The clinkers are now being used to fill up the lake front and are very valuable for this purpose, being hard and vitreous, absolutely sanitary and superior in every way to household ash. However, on account of a demand for their use in concrete construction it is proposed to install a crusher and screen and to dispose of the ground clinker by [illegible] A conservative estimate of the value of the by-products of destruction at [illegible]

Chicago Disposal.—[illegible]

[illegible]

Cleveland and Reduction Plant.—[illegible] was purchased by the city from a private company in 1905 for $87,500, the plant having a capacity of 100 tons per day. The city has since erected additional buildings and equipment increasing the capacity to 240 tons a day.

The plant was not well designed initially and it has been impossible to improve conditions by subsequent additions, the original buildings consisting of cheap sheet iron enclosures and the arrangement of equipment not conducive to economical handling. In spite of these handicaps and except for a period during a change of political administration, the operation of the plant including the collection department has been so well organized and supervised by an official with high ideals of public service as to show in 1907 a lower cost of collection and disposal than by contract in 1905, with a considerable increase in the amount of garbage handled.

The processes of reduction are, in general, similar to those employed in the Columbus plant and the local conditions which are controlling factors in the selection of the the method of refuse disposal are also similar, natural gas being used as fuel by householders and coal costing $1.85 per ton.

One of the principal ash and rubbish dumps was found to be on fire in several places.

Buffalo Reduction and Utilization.—In Buffalo, N.Y., the refuse is collected in three separate classes—ashes, garbage and rubbish—which the householders are required to place in separate cans. Ashes are carted to the dumps, garbage to a private reduction plant and all other refuse to a refuse utilization plant owned and operated by the city. The city contracts all of the collections and the reduction of garbage.

In 1907 the city purchased the utilization plant from a private corporation for $50,000. It consists of a brick building 200 x 50 feet and contained when purchased a destructor of the Meldrum type, with boiler through which the furnace gasses were passed and which produced the power required in plant operations. Since that time two boilers have been added and a sewage pumping plant. There is now being installed a destructor of the Heenan & Froude type.

The rubbish is unloaded on a receiving floor and raked into an inclined conveying apron which conveys it to a sorting room where girl pickers remove all salable material and place it in bins, the remainder passing through to the feeding floor over the destructor furnaces. This rubbish is dry or wet according to the condition when placed in the can by the householder or to the weather conditions during transportation to plant. The salable rubbish consists of paper, charcoal sacks, bags, rags, tin cans, metal and bottles. The tin cans are loaded in cars and sold to detinning companies and machinery has been installed for converting the cans into nailing caps. Bottles are sorted and sold to breweries and blueing companies, metal to dealers and old [illegible] and polishing [illegible] The plant is also credited with 70 cents per hour for steam supplied to the sewage pumping stations. The girl pickers work for $1 per day of eight hours.

The report of the Bureau of Streets for the year ending June [illegible] charges for operation of plant, including interest and repairs and also some new equipment, of $38,530.60, and receipts from the sale of rubbish of [illegible] profit for the year of $[illegible]

Rochester Incinerator.—At Rochester, N.Y., an incinerator plant has recently been installed by the Decarie Incinerator Company for the city and was undergoing its initial test at the time of the visit of Messrs. Hallock and Runyon.

The plant is of [illegible] ton capacity and is representative of the largest and most improved form of incinerator designed by this company. It is intended to handle rubbish only and is equipped with inclined conveyor from receiving floor to sorting room, where the various salable rubbish is removed by pickers and deposited in bins, the remainder passing by means of the same conveyor to and over the incinerator, where it automatically dumps into a hopper and chute to the furnace.

Between the receiving floor and the incinerator room there is a baling room equipped with a motor driven baling machine in which the paper of various classes will be baled.

In connection with the incinerator there is installed a 150 h.p. water tube boiler through which the combustion gases from the furnace pass, and thence to the stack.

The power for motor driven conveyors and baling machines and for lighting the plant is purchased from a local electric lighting company at 2¼ cents per kilowatt hour, and the steam produced has been contracted for by the same company at the rate of 10 cents per 1,000 lbs. per hour.

As this is a new and as yet untried plant there are no cost statistics to be reported.

Westmount Destructor.—Westmount is a municipal corporation which serves as the residential section of Montreal and has a population of about 16,000. The rubbish of this section is destroyed in a destructor plant which is under the charge of Geo. W. Thompson, who is also general superintendent of the light and power department of the municipality.

This plant is essentially a municipal electric lighting plant designed for commercial and public lighting purposes and erected as a protest against the exorbitant rates for lighting charged to the citizens and the municipality by the local electric light and power company. The destructor plant is an auxiliary enterprise operated in the same building, the steam generated in the destruction of refuse being used in the production of electrical energy.

The complete installation includes one 50-ton Meldrum destructor, one 50-ton Heenan & Froude destructor, five water tube boilers with an aggregate capacity of 1,000 h.p., and four engine-driven electric generators with an aggregate capacity of 1,000 kw.

The destructor plant burns garbage, rubbish and screened household ash. By screening the ash a combustible much higher in heating value is obtained, but at the expense of cleanliness, power and attendance.

There is a common collection of ashes, rubbish and garbage by the city, but when no garbage or rubbish is collected by a cart the ashes are passed through a screen. Carts drive up to the receiving or upper floor and dump their contents, which is then raked into storage bins or hoppers over the destructors. The refuse is pulled down and out of these hoppers into furnaces which are of the same type as those described in the Milwaukee plant, with the exception that clinker is handled by a car which travels on an overhead rail to a clinker yard. The clinker is used by the road department in concrete and road work and any not so used is sold to contractors.

The report for twelve months ending October 31, 1910, shows a total revenue from electric lighting and destructor plants of $102,149.17 and a total cost of operation of the combined plants of $75,426.38, leaving a net profit of $26,722.79. In the operating expenses are included interest on bonds, sinking fund for retirement of bonds and a most liberal reserve for a plant depreciation. The electric plant is charged with the heat furnished from refuse consumed. The destructor plant is credited with heat sold to electric plant, clinkers sold to private contractors, and garbage destroyed, the last item charged against the Department of Health—$9,449.06 last year.

The combined plants are ably administered under the immediate direction of Superintendent Thompson and they afford a striking example of the possibilities in a municipal enterprise of this sort when conducted with the same skill and keen business acumen that characterize successful commercial undertakings of the same magnitude. The plants are entirely free from political influence and the superintendent is empowered to engage and discharge employees, and is held strictly accountable for results

The garbage plant is free from odors and there has never been a complaint made against it, although it is situated in a strictly residential community.

West New Brighton Destructor.—The plant at West New Brighton, Richmond Borough, New York City, at the present time consumes approximately 25 tons of refuse per day at a cost of $1.34 per ton, which does not include fixed charges.

All of the power used is produced from the steam generated by the destructor gases and no sale of clinker is allowed. The plant will operate with improved economy when the quantity of garbage handled reaches a point reasonably near its rated capacity. Protests were made against its erection by householders in the neighborhood, but no complaints have been received by the department since the plant was put in operation.

Another plant of the same make and capacity, but with improved devices for feeding and clinker ejection, is being installed by the same borough at Clifton.

Scranton's Crematories.—The Scranton, Pa., plant consists of four garbage crematories of the F. P. Smith design and was installed by Lewis and Kitchen. It is designed to handle garbage and light combustible matter. Its rated capacity is 50 tons, but at times it has disposed of 90 tons per day. Combustion is at comparatively low temperature and is incomplete. No records have been kept of the temperatures and from our observations and comparison with incinerating and destructor plants we believe that the temperature in the combustion chamber is commonly below 1,250 degrees Fahr., the temperature at which garbage must be burned for the complete elimination of noxious vapors.

The plant is favored by its location next to a packing plant, the odors from which are at times highly objectionable, and on account of this circumstance any odors emanating from the crematory pass unnoticed.

The plant is inherently defective and changes have been made in its construction which increased its capacity for disposing of garbage without in any way improving its destruction from a sanitary standpoint.

Comparison of Methods.—As to refuse disposal, the authors considered dumping, the reduction system, the cremation system, incineration and the destructor system. Dumping they considered out of the question for Newark, since almost the only land available was the meadows, which would involve long hauls; moreover, as they are considered to be the future site of industrial establishments any fill made there should be such as would improve the value of the property and not depreciate it from a sanitary standpoint. "Dumps include putrescible matter, which in the heat of summer produce noxious odors and seriously interfere with the rights of adjoining property holders."

The reduction system is well adapted to cities where comparatively little or no coal is used as a household fuel and consequently where the difficulties in the way of a proper separation of household refuse are the least; but under the contract system it is always necessary to provide a bonus to induce the investment of private capital in the enterprise, and if undertaken as a municipal service it involves the installation of an equipment much more costly than for incineration or destruction and of a highly complex character.

Furthermore, the successful operation of a reduction plant is dependent upon a very efficient technical administration. In such a plant it is extremely difficult if not impossible to prevent the emission of objectionable odors, and as a rule these plants are located on the extreme outskirts of a city, an admission of the nuisance liable to be created.

The most valuable product of a reduction plant is the grease extracted, and to carry the process to its greatest refinement a percolating equipment employing naphtha in large quantities is used. This constitutes a constant menace to life and property, the destruction of plants at Chicago, St. Paul and Paterson affording examples of the dangerous character of this industry.

A reduction plant can only handle organic matter, and the contents of the receptacle of the careless householder who does not make a complete separation must go to the dumps or be otherwise destroyed by other means.

The conditions described as favorable to the installation of a reduction plant do not obtain in Newark, and the only feasible location for such a plant would be one well removed from the occupied ground on the meadows, this involving a long and expensive haul.

The cremation system or burning of garbage at comparatively low temperatures does not completely consume the organic matter, gives forth objectionable stack odors, and is generally an unsatisfactory method which does not comply with sanitary requirements for installations on a larger scale. For hotel or apartment houses where the fuel used and gases given off may be used in supplying the heat for a hot water supply system, higher temperatures may be carried, but in the case of larger installations the fuel cost for high temperature combustion would make this method prohibitive.

Incineration differs principally from cremation in the temperatures obtained in combustion, and although, like cremation, it requires the use of additional fuel, it is nevertheless a satisfactory method of refuse disposal for those municipalities which are content with their partial success in the enforcement of separate collections and the more or less objectionable ash dumps containing garbage mixed with the ash. It only partially solves the sanitary phase of the problem of refuse disposal, leaving the household ash to be carted to the dumps, and it is well recognized that a perfect segregation of the garbage from the ash is impossible of attainment, as evidenced by inspection of dumps where this system is employed.

The destructor system has previously been defined in this report as the burning of ashes, rubbish and garbage at temperatures above 1,250 degrees Fahr., but this definition should be amplified to include the requirement of artificial draft as a necessary adjunct to a high rate of combustion. This system is peculiarly favored where it is desired to utilize the power developed by the refuse consumed, but it should be kept in mind that the utilization of surplus heat is of secondary consideration, and that the primary object of mixed refuse destruction is to completely reduce the material to an innocuous clinker.

Although the combustion of [illegible] the cost [illegible] remembered that [illegible] in this system is a sanitary one, affording complete destruction of germ life in all classes of [illegible].

[illegible]

tion is correct; but where the haul to the plant is as costly as that to a dumping ground, or where it is practicable to maintain several plants and thereby reduce the length of haul, this argument cannot be upheld.

Another objection urged against the destructor system is the necessity for expert firemen, the stoking of refuse, which has wide variations as a fuel, requiring the exercise of greater skill and judgment than is the case in the stoking of coal of uniform heating value. In our opinion this argument is fallacious and based upon a very low conception of the grade of intelligence possessed by the competent stoker of boiler fires, who, in addition to his duties in stoking, is required to maintain a uniform pressure of steam and a stationary water line.

The advantages of this system of refuse disposal are many and have been most forcibly impressed upon us by inspection of the various types of plant. We list in the following the principal advantages:

First. The destruction of all organic matter in an absolutely sanitary manner.

Second. It permits the destruction of the ashes, rubbish, garbage and street sweepings, reducing all to an innocuous clinker.

Third. The fuel is supplied by the ashes, rubbish and street sweepings.

Fourth. The heat generated in combustion at high temperatures can be utilized in the production of power from which an income may be derived. A revenue can be obtained from the sale of clinker.

Fifth. A city can operate more than one plant with economy, which is not feasible in the reduction system. This permits of shorter hauls and reduces the risk of interference by fire or the failure of a part of the equipment.

Sixth. Separate collections are not necessary.

Seventh. The class of labor required in the operation of the plant is not as skilled as that required in the reduction system.

Eighth. The cost of renewals and repairs is considerably smaller than in other types of disposal plants.

Ninth. The plant may be located in the centre of the city without creating nuisance, experience at Westmount, Canada, and West New Brighton, N.Y., fully demonstrating this fact. This feature makes the system particularly desirable for Newark, where locations within the city limits would materially reduce the hauling cost

◆

CONCRETE MONOLITHS.

A system for the construction of monoliths being employed in connection with harbor work at Valencia embodies the use of moulds in the form of truncated pyramids measuring [illegible] feet square at the bottom and [illegible] feet square at the top, with a height of 26 feet. The bottom of the mould is constructed of wood and the sides of iron, and the mould is built so that the sides and bottom may be detached from one another. In operation the mould is assembled and is floated into sheltered water close to the site of the construction work. It is then partly filled with concrete by means of a crane, and is towed to the position to be occupied by the monolith, where the filling is completed. After the filled mould has been left in position for ten days the fastenings are released and the sides are raised in order to be fitted to a new bottom for a repetition of the process. The advantages claimed for this system include low cost, speedy construction, adaptability to curves and homogeneity.

AN ELECTROLYTIC STERILIZING PLANT.

A recent application of electrolysis to the industrial sterilization of water has been used in a plant in England of which the details have just come to hand. At a textile mill, which is devoted to the woolen dyeing and finishing processes, a supply of water is obtained from moorlands on which cattle are grazed, so that there is some slight contamination from this source; the result was formerly the rapid growth of algae in the storage reservoirs, which filled up the supply pipes. Grids were useless, as the fine silky threads lay across the grids in a felted mass which had to be removed with rakes every half hour, and the threads thus broken and released got into the mill and on the goods, whence they were irremovable.

Chloride of lime solution destroyed the weed but hardened the water; the result was that scale formed in the boilers and curdled the soap used in the fulling and finishing of the woolens, so the use of this chemical had to be abandoned, and the weed soon reappeared. Copper sulphate was tried, and this at once affected the dyes.

Mr. Toyne, the consulting chemist, was acquainted with Dr. Samuel Rideal's investigations into the subject of water purification, wherein the use of electrolytic sodium hypochlorite was advocated, and as a last resource he tried the electrolyzer made by Messrs. Ernest Grether & Co., of Manchester. After three days' trial this proved entirely successful; the weed was killed, and the water—which had previously been tinged slightly yellow, owing to the infiltration of peaty matter—was changed to the ordinary blue-green of pure river water. The proper strength of chlorine to effect the purpose was ascertained by experiment, and amounted to about two parts chlorine to 1,000,000 parts water. The little "Manchester" electrolyzer which was used is illustrated in diagram herewith. A couple of planks were thrown across the little stream which fed the reservoir, and the apparatus was mounted on these, so that the electrolytic sodium hypochlorite, as made, trickled into the brook, and was thus intimately mixed with all the water that entered the reservoir. An automatic feed tank was provided at a higher elevation, and a hogshead of brine, higher still, as shown, so that, after filling the hogshead once a day, the operation of the plant was entirely automatic. A little roof, not shown in the diagram, protected the apparatus from the weather. Current was provided from the mill-lighting circuit at 110 volts by means of an overhead line; the current amounted to about 8 amperes, and the overflow from the electrolyzer was at the rate of 1 litre per minute, with a strength of 3 grammes active chlorine per litre. The brine had a strength of 4 per cent.

When the amount of chlorine required had once been determined, it did its work in the reservoir, and spent itself on the organic matter therein; there was no chlorine present at the outflow. Daily chemical tests failed to show either chlorine or nitrogenous matter, and the dyes were not affected. If any free salt was present, the quantity was too small to be detected, and in any case it was harmless. The water was excellent for drinking purposes, and, in fine, the experiment was a great success from every point of view.

The subsequent development of this experiment is even more interesting: as winter set in, it was decided to stop the electrolyzer, as no growth of algae takes place in cold weather; at the end of a fortnight complaints were made of the reappearance of peculiar markings, or stains, on the material in course of treatment, which excited comment, seeing that this old trouble had been absent during an exceptionally hot summer. The bacterial action of the water was at once suspected, and the electrolyzer was restarted, when the fungoid growths at once disappeared. Needless to say, instructions were issued to run the electrolyzer henceforth summer and winter.

Further experiment has shown that in winter, when the growth of vegetation is suspended, the amount of electrolytic sodium hypochlorite may be reduced to 1 part per million, the contaminated water thus treated refusing to show any action on gelatine plates.

The importance of this later discovery calls for special emphasis, for it appears to have a much wider bearing than the original application of the system to prevent the growth of algae. The bacterial growth or mildew above-mentioned has long been a source of continual trouble in many bleach works, and has previously been ascribed to local infection, such as contact with old wood on floors or stillages infected with mildew, inferior sizing materials, etc., whereas it is now traced to the true cause—contaminated water supply—and simultaneously the remedy has been revealed, in the shape of the electrolytic sterilizer.

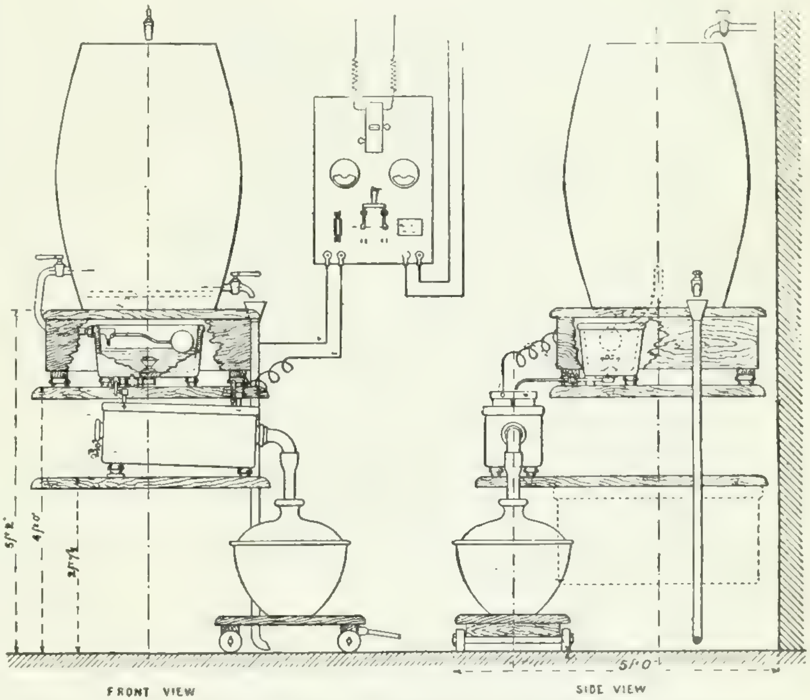

Diagram of Electrolytic Sodium Hypochlorite Sterilizing Apparatus.

The cost of working was estimated as follows:—Taking the cost of energy as derived from the mill at about 5 cents per unit, and running the plant at 8 amperes for 10 hours a day, the consumption of energy was 110 × 8 × 10 = 8.8 units, costing, say, 4 cents a day. The brine used amounted to 132 gallons of 4 per cent. density per day, requiring 52 lb. of salt, which, at the price paid by the dyehouse, cost 10 cents. The labor and attendance required was negligible, and the total cost thus came to about 14 cents a day.

The installation was at work all last summer during the exceptionally hot season, and has been in operation for nine months to the entire satisfaction of the owners of the mill. The system is, of course, applicable to a great variety of cases in which water is contaminated with organic impurities—for example, it can be used to purify the water of swimming baths, as is already done at Poplar by Dr. Alexander, with excellent results.

EXPERIMENTS IN OIL SMELTING IN BRITISH COLUMBIA.

The annual report of the Minister of Mines of British Columbia for 1911 contains some notes by Wm. Fleet Robertson, Provincial Mineralogist, on attempts to smelt with oil as fuel. For the past two years the Dominion Oil Smelting Company, Ltd., in Vancouver, has been conducting a series of experiments in the old Van Anda smelter, in an attempt to perfect or render practicable an oil-fired furnace for smelting ores, and has achieved a degree of success such as to render the process worthy of serious consideration. The particular form of furnace being experimented with is covered by Canadian patents granted to J. J. Anderson, and acquired by the company. More recently, March, 1912, Mr. Anderson has taken out United States patents for a new furnace, which is a modification of the Van Anda furnace, designed along lines suggested by Mr. Thomas Kiddie after the latter had made a test at the Van Anda plant.

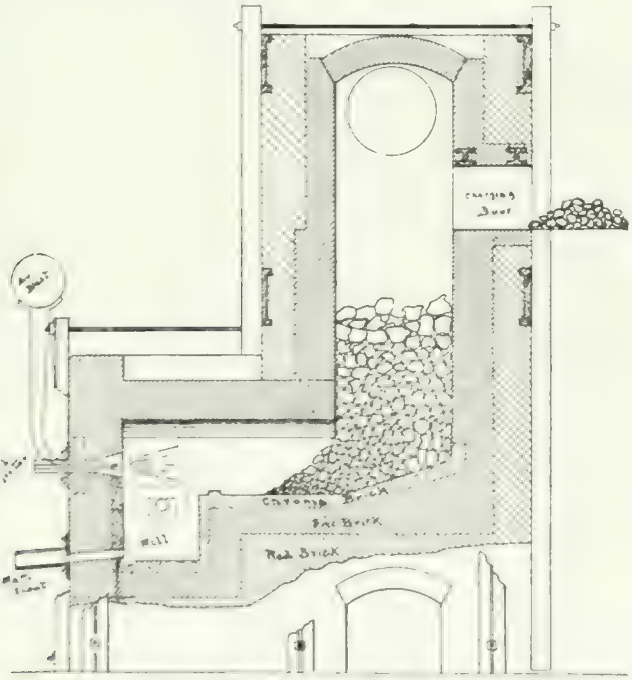

Fig. 1.—Dominion Oil Smelting Co., Oil Furnace Blast Furnace at Van Anda, B.C.

The Van Anda furnace, of which a sketch is given as Fig. 1, is, essentially, a shaft furnace superimposed above one end of a reverberatory furnace or combustion chamber. As previously the ore, with suitable fluxes, is fed into the shaft from the charging floor, passing down onto one end of the reverberatory hearth. The shaft thus serves as a feeding hopper for the reverberatory. The latter is fired from [illegible], which burns sprayed oil into the front of the chamber, the flame impinging on the foot of the ore column in the shaft. The products of combustion pass [illegible]

The present [illegible] that a considerable advance has been made toward that goal is indicated by the results of a test made by Mr. Thomas Kiddie, a metallurgist of British Columbia, who has had previous experience with oil-fired furnaces at the works of the Orford Copper Company, New Jersey.

MANAGEMENT OF TRACKLAYING ON NEW RAILWAY WORK.*

In the discussion of the methods employed to obtain the best and most economical results with tracklaying on construction work, the committee has limited itself to the consideration of the following points: (1) Should the building of new yards and main lines (which are not let to contractors) be handled exclusively by the engineering departments? (2) Should such work be handled by the maintenance-of-way department? (3) Should such work be placed under the direct supervision of a practical track man?

In regard to the first point, the plans, specifications, etc., should be prepared by the chief engineer, but the actual supervision of the work should be in charge of a practical track man. There should, of course, be a resident engineer on the ground to lay out the work in accordance with the specifications.

The man in charge can best ascertain the proper kind of material to be selected and the manner in which it should be placed on the subgrade in order to eliminate the possibility of soft spots which so frequently develop in tracks under the pressure of heavy traffic and which form the most serious drawback in the maintenance of a first-class track in the future. He can also provide good drainage, sufficient ballast under the ties, and proper spacing and placing of ties in accordance with the size and condition of ties provided, all of which are essential to the construction of good, substantial tracks. The construction of all new track work or such tracks as come under the head of "construction work" should be completed in detail at the cost of construction before being turned over to the maintenance department.

As to the second point, such work should not be handled by the maintenance-of-way department, for the reason that the average roadmaster has as much maintenance supervision as can be properly looked after, particularly during the working season.

As to the third point, work of this character should be in charge of a practical track man, selected by the proper officials, together with a resident engineer.

A saving in cost and time can be obtained by the use of a tracklaying machine in laying the first track, depending largely (of course) on good organization. Second and other additional tracks can best be constructed by unloading the necessary material from the existing track; this applies also to yard tracks. All necessary grading can be done by train to very good advantage when the material is not at hand to be hauled by teams.

The advantage in making fills by train lies in the fact that better material can be obtained and used after the material is unloaded from the train with a side plow and leveled back to the full depth and width for an additional track. If gravel ballast is to be used it can also be unloaded and spread on the grade with a spreader to the width and height required before tracklaying, so that when the steel is laid there is no ballasting to be done beyond unloading on a light lift [illegible]

---

*Abstract of a committee report presented at the annual meeting of the Roadmasters and Maintenance-of-Way Association, Buffalo, N.Y., Sept. [illegible]

THE DESIGN OF GIRDER AND TRUSS SPANS AND TRESTLE WORK IN STRUCTURAL STEEL.

The present status of structural steel designing was discussed by F. W. Dencer, Chief Engineer for the American Bridge Company at the Gary, Indiana, Plant, before the Civil Engineering Society of Valparaiso University in a recent lecture. Many details of design were discussed for various types of structures. The paper in full is published in the Engineering Annual of the University and is here abstracted.

At the close of the last century, structural designing had reached, as it seemed to us, a very high stage of development. Yet in fifteen short years, many of the designs were relegated to the files, never to be used again. Bridge and structural designing had gone through a remarkable series of evolutions and who can say that we are nearing perfection? The chances are that in the next ten years the progress made in scientific designing will be as great, if not greater than the progress made in the last ten years.

Undoubtedly, many phases of designing will be better understood, as for instance, (a) the treatment of connections to resist secondary stresses, (b) the forces produced by impact of the drivers, (c) effect of temperature on initial stresses, (d) deformation of trusses, (e) action of columns under stress, (f) action of the top chord of through plate girder spans, (g) theory of bearing surfaces and proper materials to be used in their design, (h) use of stiffeners, etc. The speaker does not wish to convey the impression that these subjects are not understood, at the present time, but that further developments along these lines are possible and very desirable.

The tendency of the future in structural engineering, will probably be along the lines of standardization. That is, through the co-operation of various railroads, a uniform train clearance will be adopted, wheel loads for two or three different types of engines will probably be used, the steel material will be rolled to the same specifications and be of the same quality and finally engineers will agree on a uniform set of specifications for workmanship. Some attempts in this direction have already been made, as is evidenced by the work of the American Railway Engineering and Maintenance of Way Association in producing the specifications which are used by many railroads and corporations and also on the Common Standard drawings which are used by the Harriman Lines.

The engineering profession has depended on the following agencies for means for improvements in the past and developments to be made in the future: 1. Designers of railroads and bridge companies who are continually making use of new ideas based on the observation and action of existing structures. 2. Research work and investigations at testing laboratories and universities. 3. Discussions and papers of engineering societies. 4. Improvement in the quality of materials and the use of alloys.

Not many years ago, the longest angles obtained from the mills were 60 ft., to-day angles 125 ft. long may be obtained. Besides new sections have been rolled which permit of greater possibilities in designing, such as 8 x 6-in. angles, 24-in. I-beams, etc.

To show the importance of the quality of material in its relation to designing, it might be well to call attention to special materials which have recently (within the last decade) come into use and have served to revolutionize existing methods of design.

Cast steel, because of its high tensile and compressive strength and its adaptability to conform to different shapes is used quite extensively for bearing boxes, shafts, shoes and bearing bolsters. It is used often for details where heretofore castings were prohibitive. A small quantity of aluminum is commonly added to the cast steel. It permeates through the entire mass without artificial stirring and adds to the ductility of the steel as well as preventing blow holes.

Because of the high price of cast steel, engineers were forced to design a great many details of rolled steel which from the standpoint of strength and good designing, was inferior to the cast steel designs. In recent years, the price of cast steel has dropped and engineers are using cast steel more extensively. The new Municipal Bridge of St. Louis just erected has chords of nickel steel.

Metallic nickel, nickel ore, or ferro-nickel to the extent of 3½ per cent. of nickel is added to the bath of steel made by the open hearth process. The nickel increases its density, elasticity and strength. The high elastic limit of nickel steel tends to prolong the life of the metal and because of its superior toughness, offers greater resistance to sudden strains and shocks.

Phosphor bronze, a combination of tin, copper and phosphorus, is used for bearings which are subject to high pressures and run at slow speed.

Lumen metal manufactured and patented by the Lumen Bearing Company is also used for bearings. It contains zinc, copper and aluminum. The advantages claimed for this metal are its light weight and low coefficient of friction.

Other alloys of varying proportions and metals are used for frictional surfaces, the most common of which is babbitt metal. It is composed of lead, tin, zinc and antimony. For high speed metal the base is tin, and for low speed the base is lead.

Manganese steel is used for purposes where an extremely hard metal is required, as for rail locks, frogs, or switches. The material is too hard to cut with a tool and must be ground where a finished surface is required.

Improved processes of making and rolling structural steel have enabled engineers to design structures with a higher degree of efficiency for the same weight. This statement must be taken within certain limits, due consideration must be given to the greater deformation caused on the material when the ultimate stress, and consequently the working stress, increases per square inch.

The use of alloys and special materials is mentioned briefly to show that their uses have much to do with the progress made in designing. In other words, many details that recently have come into use would be impossible were it not for the scientific progress made in steel manufacturing.

As this paper will deal principally with designs for the most practical details, we will attempt to show that many details can be simplified and made more practical without impairing their strength and often with better results.

The best design of structure is one which has the smallest number of members to resist the stresses, also each member designed with a minimum number of component parts, provided, of course, that due consideration is given to the proper distribution of the material. In other words, the simplest design is the best, other considerations being equal.

Girder Spans.—The depth of a girder is generally taken as the economic depth. This can be determined by expressing the weight of the girder in terms of the unknown depth. Frequently the depth of the girder span is determined by other considerations, such as the base of rail to masonry being fixed or to make suitable connections to adjoining spans.

An important step is to decide on the "building up" of the top flange. To avoid dapping of the ties, some railroads use four angles with side plates between. This method leaves the top flange clear on top without and projecting rivet heads or cover plates. The bottom flange is commonly made up of two angles and sufficient cover plates, the weight of the cover plates being about equal to the weight of the angles.

For the [illegible] of the top flanges of through plate girder spans engineers differs as to what formula to use to resist the deflection sidewise. Reliable tests are lacking, which would definitely determine the resistance necessary to prevent buckling. All engineers, however, are agreed that the ratio of "l" over "r" should come within certain limits, and in addition thereto the floor beams are extended by means of brackets, within the line of train clearance, to connect to the top flange. Sometimes assumptions are made, such as treating the top flange as a column free at both ends and with an effective length equal to two-thirds of the length of the girder.

For length of girder spans up to 60 ft. the expansion ends slide on castings, the effect of the deflection not being considered except that the casting should not be too wide on top. For longer spans shoes with pins are used to permit deflection. Roller nests should be used for the expansion ends. Segmental rollers about 6 ins. in diameter are better than the circular rollers, as more rollers can be used within a given area.

Pin shoes should be designed of cast steel instead of being built up of plates and angles. The distribution of bearing necessitates the use of stiffeners which in the shop are extremely difficult to secure a perfect bearing at the bottom, certainly from a theoretical standpoint a perfect and equal bearing of all stiffeners is impossible.

When designing end posts of girders the bearing areas required should be confined to as small a space as possible to prevent unequal transmission of the shear under deflection. The centres of the end stiffeners are placed exactly over the bearing casting. It is best to lay out the bearing castings with the end of the girder to make sure that the walls of the castings are placed under the bearing surfaces of the girders.

The chamfered legs of the end post angles which fit the fillets of the flange angles should not be counted in bearing, as the shop does not get a fit perfect enough to transmit bearing. The outstanding legs are figured only for bearing. The value of the rivets through the flange angles which are above the sole plate or bearing shoe will add to the strength of the bearing, but should not be counted in the computations.

Through plate girders are frequently designed with round ends; the reason commonly given is that the round ends will deflect any material protruding from the side of the car. This method of construction is very expensive and should be discouraged, at least be restricted to the ends of the girders having considerable projection above the base of rail. The speaker does not believe that from an æsthetic point of view the round ends are better.

[illegible] plates are used with round ends the side plates should be cut where the bottom edge meets the curvature of the flange angles. The space under the flange angles beyond the end [illegible] the end reinforcing plate should be filled with plates. This detail will simplify the shop work.

[illegible]

The cross frames should be connected directly to the top [illegible]

Engineers differ as to the use of stiffeners in stringers. Where stiffeners are not used a common specification is that the unsupported distance between the flanges should not be more than 60 times the thickness of the web. The thickening up of the web to conform to this specification and the omission of the stringers does not alter the weight materially; sometimes the weight becomes greater and sometimes smaller, and in addition has the advantage of simpler fabrication to the manufacturer and reduced cost to the buyer.

For all skew span work it is advisable for simple fabrication to study the design with the object of squaring the end frames, end stringers, etc. Frequently the skews of various spans vary by small amounts which, for practical purposes, could be modified slightly to make as many spans of one skew as possible. When designing more than one span the location of piers or bents should be studied with the idea of making as many spans of the same lengths as possible.

Truss Spans.—Inclined top chords are generally used for spans over about 200 ft. in length. For spans over about 300 ft. in length sub-verticals are used in order to give a better inclination to the diagonals. In the designs of the longer spans it is usual to connect the compression members which are built up of structural steel with riveted connections and the eye ears are connected with pin connections.

The interior columns should be designed not merely to conform to the column formula, but also to give good connections for the floor beams and bottom laterals.

Generally the flanges of the built-up members should turn out and not in, where for good packing it is necessary to turn in the flanges of the posts and diagonals; the flanges of the top chords and end post should always turn out. By turning out the flanges of built-up members the rivets in the tie plates and lacing bars can be more easily driven. To resist the thrust of the drivers as the engine comes upon the bridge the end bottom chords are generally made up of built sections for two panel lengths.

The top chords and end posts are built up of web plates, top and bottom flange angles and a cover plate. The bottom angles, which are laced, are made heavier than the top angles, so that the centre of gravity of the section may be more nearly in the centre of the member. Heavier angles give simpler shop work than the addition of bars riveted to the angles. If the desired section cannot be obtained with single webs, the webs should be doubled rather than by adding side plates between the angles. The plates between the flange angles are not connected to the angles and do not give as rigid a section as the additional webs do. Double webs may be held together in the centre by one line of rivets about 12 ins. centre to centre.

When designing sections for chords and columns of trusses the designer should draw the sections of the various members, taking into account the fitting of the posts to the top and bottom chords, so that there is clearance enough for lacing posts and bottom chords. Sometimes designs are received in which the posts are too narrow to permit a floor beam connection; again the chords are too narrow to allow the riveter to rivet the lacing bars when the angles are "turned in," and again the angles of the chords are too small to give room enough to drive the cover plate rivets where pin plates occur.

The working lines of the top chords and end posts on which the pins and intersections of posts and diagonals are located should be approximately the centre of gravity of the sections, but the fact should not be overlooked that the weight of the member itself lowers the centre of pressure. Consequently, if the eccentricity is small, the working lines may be taken on the centre line of the chord. To reduce the eccentricity of the [illegible] connections to a minimum the working lines of chords, posts and diagonals should meet at a point. Also care should be taken in spacing an equal number of rivets on each side of the centre of a member for the connections. Extreme care should be taken to avoid eccentricities at connections as far as possible.

For lateral or wind bracing connections it is a common error to connect the lateral plates to resist the stresses along the line of one component only. The connections should be made to resist both components. A difficult connection to make is at the point where the bottom laterals connect at the abutment. For the best design the transverse component should be carried direct by the end floor beam and the longitudinal connection by the bottom chord. As noted before, the end bottom chord should be a stiff member.

The bottom laterals are generally connected to the bottom of the posts and to the bottom flanges of the floor beams. The longitudinal component of the wind stress must go from the bottom of the post up to the pin to be carried by the eye-bars. As this eccentricity is unavoidable in our present designs, the posts must be designed to resist this bending. This is accomplished by a plate on each side of the post running to the bottom of the post and above the pin to be utilized also as a pin plate. For the large wind stresses it is advisable to design these reinforcing plates wider than the post to add greater resistance to the bending of the posts.

As the posts cannot be laced from the floor beam to the pin, this part of the post should be amply strong, by cutting the outstanding legs of the angles as little as possible, by extending the pin plates up to reinforce the weak section and by using as few countersunk rivets as possible. Countersunk rivets are not as good as full-head rivets in bearing and, besides, remove more of the section of the plates they connect by the counterboring. The chipping of the countersunk rivet also weakens the rivets by loosening them.

Eye-bars should be designed to conform to the dies of the manufacturers. It will be found that ins. is the maximum thickness for eye-bars, for tests have demonstrated that the thicker bars are not as efficient in tension per square inch as the narrower bars. It is recommended that only two or three sizes of pins be used on a span. If the pin is too large for the bending stresses the pin plates may be correspondingly reduced. Besides, the eye-bars will be more uniform and a less number of pilot and driving nuts are used. Pinplates for transmitting bearing to the pins should be designed with the idea that the web plate is transmitting its own bearing, therefore the bearing from the chord angles to the cover plates should be transmitted through the chord angles to the pinplates direct.

As truss spans are riveted up in the field after the span is "swung" clear of the blocking, the ends of the top chords at the splices come to a bearing for dead load only, consequently the splice plates should be designed heavy enough to carry at least the live load stresses.

In good designing splices should be avoided on the principle that a splice, even if excessively strong, is never as certain of action as a full member. It is important in a splice to secure a proper distribution of material and rivets. The reinforcing material should be adjacent to the material spliced, with the correct number of rivets to each part of the splice. For instance, it would be manifestly wrong to splice a 6 x 4 in. angle by putting all of the splice material on the 6-in. leg.

On through truss spans the tendency is for the stringers to elongate as the bottom chord stretches. It is therefore advisable to design the stringer connections with a wide gauge for the rivet lines to permit the connection angles to "spring" under deflection.

On deck truss spans, having the stringers riveted between the floor beams, the top chord compresses and becomes shorter, tending to throw compression into the floor system, but in reality bowing the stringers outward. To offset this condition the stringers are built a trifle short for short spans, or one expansion pocket is provided at the centre of the span for spans over 300 ft. in length.

On deck trusses where the stringers rest on top of the floor beams the difference in movement between the top chord and the bottom flanges of the stringers is the shortening of one panel of top chord plus the elongation of the bottom flange of the stringers. This movement is taken care of by slotting the holes of one end of each stringer. In such a case the top laterals should not be rigidly connected to the stringers. The only connection necessary is such that will support the weight of the laterals to prevent sagging.

Bottom laterals should always intersect at the centre line of the truss where eye-bars occur in order to prevent the twisting of the post. This is not so essential when the bottom chord is a built member, as the stiff member carries the stress from one side to the other. The objection to having central connections where stiff members occur is that the lateral plates become very long and ungainly. However, when eccentric lateral connections are used, the two sides of the member should be rigidly connected.

Top chord sections are usually shipped in two panel lengths. The engineers should remember this and design these sections of the same material to avoid the shop splice. The weight is practically the same and the member is stiffer without the splice.

The wide lacing bar having two rivets at each end is advocated instead of the narrow bars with one rivet at each end. In addition to its greater efficiency the wider bar is more easily riveted.

For truss spans the reaction of the end floor beams should be carried on the end pin and not on the shoe. This will enable the end beam to take up deflection with the trusses and also place the loading more central on the main shoe. The pin shoes, as noted elsewhere in this paper, should be of cast steel, while the main bolsters should be of cast steel or cast iron, depending on the amount of reaction.

The tractive force of the engine exerted when the brakes are set has a tendency to bend the floor beams in the direction of the moving load. This force, which is usually taken at one-fifth of the vertical moving load, is resisted by the stiffness of the floor beams for small spans. For long spans, say over 250 ft. long, it is best to provide a truss frame to carry the tractive forces over the trusses. For a solid floor, such as a trough section floor, I-beam floor, or where four lines of stringers are used for single track, the provisions for bracing against tractive force may be neglected.

Trestle Work.—The design of the viaduct will depend upon economic conditions and on the equipment for erection —that is, the length of span is determined from the length of boom on the traveller or derrick car. We are not concerned with the erection in this paper, but this point was brought out to show that all phases of construction should be considered.

After deciding on the lengths of the main girder and tower spans, the elevation of the trestle should be determined by making the tower spans of one length, and as many as possible of the main spans of one length. The elevation at the top of the piers should be fixed with the object of making all of the tower posts alike if possible. If the contour of the ground will not permit this, the tower lights should vary only where [illegible]

It is recommended that the tower spans be made of the same depth as the main girders. This has advantages, as omitting the brackets for carrying the short spans and utilizing the bottom flange of the tower span for the top strut of the longitudinal bracing.

From the point of view of the erector the erection is simplified by making the main girders and the tower spans of the same depth, for the reason that the traveller or derrick car can be run on the tower spans easily, whereas, in the case of the shallow tower spans, it is necessary to block up one end of the span and slide in the long girders afterward.

When the track is on a grade the two bents of any one tower should be made identical by adding fillers on the tops of the columns which are on the up-grade side of the tower. This provision simplifies the fabrication of the steel considerably.

The deflection of the main spans when over about 70 ft. in length throws the bearing pressure on the edge of the base plate. This unequal distribution of pressure may be overcome by the use of a short base plate or by having the girder reaction carried on a narrow strip of steel placed transversely to the length of the girder.

To secure the proper bearing of the columns on the masonry the stress must be distributed over an area considerably larger than the area of the columns. The best way to accomplish this is to provide a casting which flares out to the required area and the base of the column will be simplified without the use of elaborate wing plates, diaphragms, etc. It should be remembered in this connection that fitted stiffeners, wing plates, etc., are difficult to fabricate so as to insure bearing contact through the milled ends.

The diagonals of the longitudinal and transverse bracing are tension members. For simplified shop work it is recommended that the angles of these members be held together with tie plates and not with lacing bars. Narrow struts composed of four angles in the shape of an I-beam are perfectly riveted up with a solid web plate instead of being laced. The weight in either case is practically the same as the solid web may be utilized as part of the section of the strut.

Wide struts, of course, should be laced rather than built up with a solid web in order to save the weight.

Column sections are generally shipped in lengths not exceeding 60 ft. The engineer should design the column for the length of one shipping piece of the same cross section. [illegible]

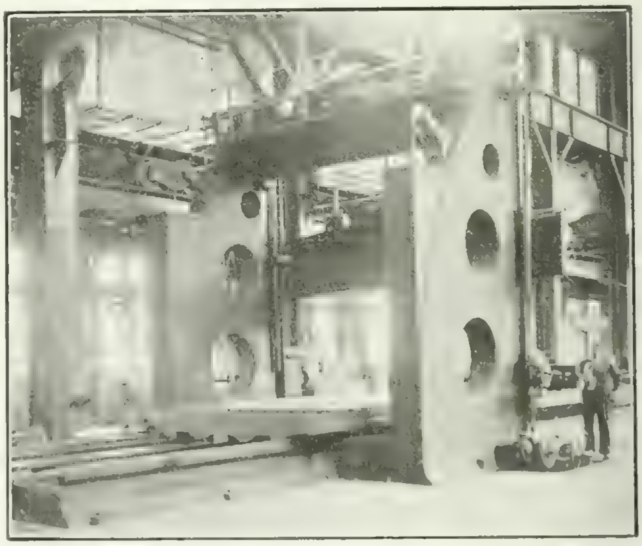
A LARGE PLANER.

The planer, which is illustrated, was built by the well-known firm of Ernst Schiess, Limited, in Duesseldorf, Germany, and was furnished some time ago to the Mesta Machine Company in Pittsburg. When Mr. Mesta was in Europe some time ago he found that a great many large machine works were using Schiess planers, and was favorably impressed with the advantages of the German design. He consequently placed an order for such a Schiess planer with the agents of the German firm, the Wiener Machinery Company, 50 Church Street, New York, N.Y. The machine is now in successful operation for some time, and it may interest our readers to get acquainted with some data of this big planer. The machine has a planing length of 33 ft., a width of 13 ft. 1 in., and will accommodate pieces 11 ft. 6 in. high. There are four toolholders, two at each standard. All these holders are arranged for automatic setting in a horizontal, vertical or inclined position up to 45 degrees, and are furthermore provided with a quick-acting power arrangement, to be moved at the rate of about 2 ft. per minute, and an automatic lifting of the tools when the table is running back. The cross-rails can be lowered or raised at the rate of 10 in. per minute. All these quick changes can be made independently from the main drive of the machine, and this is accomplished by means of a 12 horse-power motor arranged on top of the machine. This motor is easily accessible from a bridge arranged for this purpose. Of course, the motor is operated in different ways very easily from a switch on the right side of the machine. The table, which is 10½ ft wide, and arranged to permit an easy removal of the shavings, runs in three wide, flat grooves, which are provided with a very good, durable and automatic oiling system. The table is driven by two broad steel racks by means of a 50 horse-power reversible motor. The motor runs with between [illegible] in such a way that when the table is running [illegible], which [illegible] and backward [illegible]. The machine complete without its motor, which was furnished by the Westinghouse Electric and Manufacturing Company, weighs about [illegible] pounds.



View of Planer.

A BRIEF DESCRIPTION OF A MODERN STREET RAILWAY TRACK CONSTRUCTION.[*]

By A. C. Polk.

With the increasing demands made on various traction companies throughout the country to provide good service, the matter of securing a permanent roadbed in the busy and paved sections of a city has become a serious problem. When the work is poorly done originally, and is not on a proper foundation, the cost of maintenance is increased, the paving along the poor roadbed becomes cracked and ruined by the movement of the track, unfavorable public comment on it arises, and the company finds itself face to face with one of two propositions, either the entire rebuilding of the roadbed or the attempt to surface and repair the old one. Either alternative is expensive, as the work will have to be done on a busy street and will interfere with car schedules, with consequent loss of revenue to the company and inconvenience to the public. Therefore, when the paving is done originally, the permanent roadbed should be substantial and effective.

In this paper the writer has attempted to give a general description of the methods and materials used at Springfield, Mo., in rebuilding the Springfield Traction Company's lines on streets which were being paved by the city during 1911.

The company's franchise stipulates that it shall pave the space between its rails and for two feet outside of the rails, when the city paves on the various streets occupied.

The work was done by the company, under the writer's supervision, and aggregated more than three miles of new tracks.

It was desired to secure as permanent a roadbed as possible, in fact, one which would outwear the rail itself and allow its replacement without disturbing the roadbed if so desired. Fig. 1 shows the general cross-section and detail of the work as put in.

General Features.—The general features of the structure were, a 7-in., 70-lb. **T**-rail section, 62 ft. long, laid on steel ties, and directly under each rail longitudinal concrete beams, each reinforced with two ½-in. twisted steel rods, and a 5-in. concrete mat over the beams and the centre of the tracks for a paving foundation.

Fig. 1.—Section of Concrete Steel Tie Track Construction.

In this case the city contractors were allowed to place the street pavement first, except where it was of asphalt. After the paving on each side of the track had been completed, the old track was moved to one side or the other on the completed pavement, and excavation between the tracks was commenced.

Excavation.—The standard depth below the finished pavement to which the general excavation was made over the whole 9-ft. space was 10 in., as shown by Fig. 1. Then two trenches were excavated to exact dimensions, a depth of 9 in. more, and running with the rail. At the joints these trenches were connected by cross trenches, 30 in. wide at an additional depth of 3 in., so that each joint tie would be thoroughly embedded and have a good thickness of concrete under it. Around each intermediate tie shallow trenches were excavated so that there would be at least 2 in. of concrete under the tie and 4 in. around its sides.

Ties.—All ties were punched at the proper gauge to take 7-in., 70-lb. or 80-lb. **T**-rails, but the 70-lb. rail was used principally. There were two types of ties, one under the joints which came opposite one another, and the other intermediate between them. The joint tie was an **I**-beam section, weighing 20 lb. per ft., 6 ft. 8 in. long, having an 8½-in. top, on which the joint rested, and a 4½-in. base. The intermediate ties were of the same length, but weighed 14.5 lb. per ft. and had a 6-in. top and a 4-in. base. All ties were spaced 5 ft. apart, or as near that as the distance between joints would permit.

Fastenings.—The rail was fastened to the tie by special lugs and **T**-headed bolts with square shoulders next to the head. These bolts could be inserted from the top, if so desired, being dropped through the rectangular hole punched in the tie, turned, and then raised until the square shoulder fitted up into the rectangular hole, which prevented it from turning while running down the nuts. The lug had a projection on its under side which also fitted into the rectangular hole, and prevented it from turning or backing off the rail. A socket wrench was used to run down these bolts rapidly. The joint ties were heavier and wider than the intermediate ones, as noted above, and were punched to allow the lug to fasten over the continuous joint which was used.

Joints.—Six-bolt continuous joints were used, and the following method of making them was adhered to with greatest care, as the joint is generally the weak part of the track work:

First, those parts of the rail with which the joint came in contact were carefully cleaned and polished with files and emery cloth until all scale, rust, and particles of dirt were removed and the surface was bright. Then those parts of the joints which came in contact with the rail received the same treatment. All contact parts were then greased and the joint put on. The tightening of the bolts was started from the centre, working out toward the ends, pulling up a bolt on one side of the centre and then the corresponding bolt on the other side, and when the bolts were all apparently tight a heavy sledge was held against the bottom of the joint on one side and the other side tapped briskly with a light sledge at the bottom only, and vice versa.

---

[*] Paper to be presented to American Society of Civil Engineers, Oct. 16th, 1912, and published in the August proceedings of the society.

Then the tightening process was repeated until nothing more could be gotten out of the bolts by one man with a wrench having a 30-in. handle. After a continuous joint has once been carefully made in this manner it is there to stay, and even if the bolts were removed the joint would remain under traffic for a long period without any signs of loosening. Another feature in making a joint of this type in this manner is that no bonds were used, or considered necessary. The net area in contact has a far greater current-carrying capacity than the No. 0000 copper bond generally used on heavy lines, and a test showed no trouble with return circuits. It has also been brought to the writer's attention that a section of track put down in a similar manner showed a first-class negative return circuit after two years under traffic.

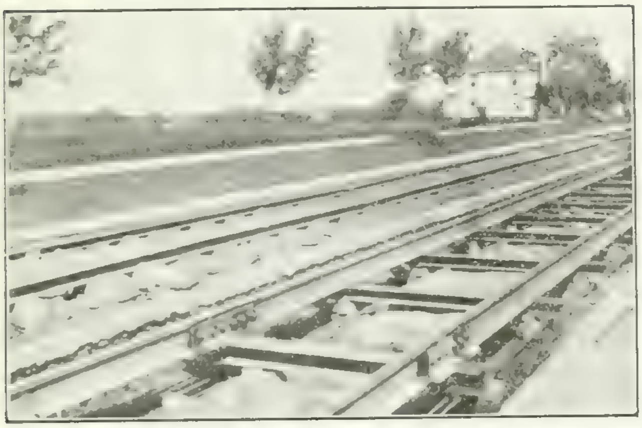

Fig. 2.—Reinforcement at Joints and General Construction.

Surfacing and Preparing for Concrete.—The track, having [illegible] as described, was supported on small piers of old brick placed under every other tie, and centring under the rail. The final surfacing was done with oak wedges on top of these piers, and both the piers and wedges were concreted in.

Two ½-in. twisted steel rods were placed in the bottoms of the trenches about 6 in. square. These also were supported at intervals on top of a brick which held them about 2½ in. off the ground. Under each joint two extra 4-ft. lengths of these steel rods were placed, to give additional strength at this point, which is usually considered the weak spot of track construction. This is shown on Fig. 2.

The track was then given its first surfacing raise, being [illegible] in keeping the skeleton track in correct line, variations in temperature kinking it.

Concrete.—[illegible] the mixer in such manner that they were about in the right proportions. These materials were cleaned up as the mixer progressed.

Of the two methods, the latter was found to be by far the most satisfactory, as there were frequent delays in the delivery of materials to the first mixer by the work train, and the temporary track was blocked for traffic beyond the point where concreting was in progress and, on single-track work, passengers had to transfer around the obstruction.

In the second method, all material could be delivered on the street for a considerable distance ahead of the mixer, and there was no reason for the mixer to be idle at any time on this account.

The concrete was composed of 1½-in. (maximum size) crushed limestone, Kaw River sand, and chats from the Aurora Zinc Mine district, the proportions being one of cement, two of sand, two of chats, and three of crushed stone, this making a very good mixture. The concrete was mixed very wet, dumped into movable chutes from the mixer, and deposited directly by them on the track. Great care was taken at all times to keep all loose material in the excavation cleaned up ahead of the concrete and to maintain the twisted steel rods in their proper positions. The concrete was puddled carefully under and around all ties with shovels and finally crowned, when it reached grade, with a special board or templet made for the purpose.

When the material through which excavation had been made was of a very loose character, or if bad weather had caved in the sides of the trench, forms were placed where necessary to hold the concrete to the exact dimensions of the roadbed. After the concrete had set for 48 hours, and in the majority of cases longer, the brick paving was done.

Paving.—The paving was of first-class paving blocks, laid on a 1-in. sand cushion, and grouted. The method of laying it differed somewhat from the usual practice. Along each rail, and snug up against it, was laid a 2 by 4-in. piece of timber. A stretcher course of bricks was then laid against it paralleling the rail, the tops of the bricks being only ⅛ in. below the top of the rail. The headers across the tracks were then laid and all the bricks were thoroughly rolled and rammed.

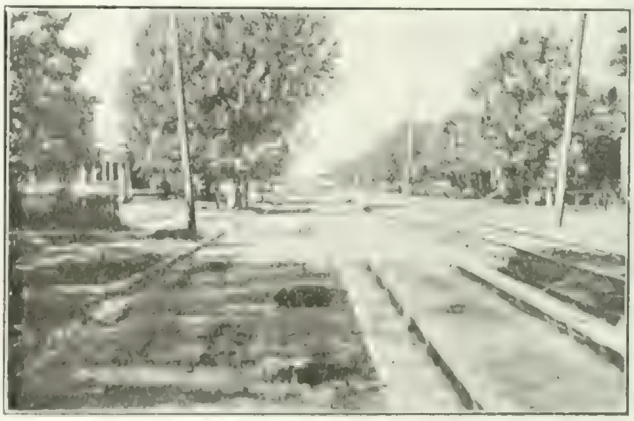

Fig. 3. Concrete and Track Work Complete, Ready for Brick Paving.

Before grouting, the 2 by 4-in. piece was removed and the space [illegible] concrete to a plane 1 in. below the top of the rail, forming the flangeway for the wheels. After this had set, the [illegible] pavement was grouted thoroughly and carefully. When [illegible] up, the grout remaining over the top of the pavement was allowed to stand until it had [illegible] set and was fairly stiff, then dry sand was sprinkled over it and the whole was swept thoroughly with wire brooms, thus removing all surplus grout sticking to the tops of the bricks and presenting a very neat, clean surface. It was noticeable, too, how very much the paving contractor improved in the character of his work, when this specification of cleaning off the top of the brickwork was strictly enforced. By this method all irregularities of laying and surfacing are strongly brought out, and easily seen and corrected.

Cost.—The cost of track construction of this type for paved streets, including the paving between and for 2 ft. outside of the rails, using the 70-lb. high T-rail, under the conditions at Springfield, was approximately $5 per ft. of single track. This cost may seem to be high, but, when the permanent character of the work is taken into consideration, and the cost of doing street work under other methods is analyzed and compared, it will be found to be very reasonable. It possesses several advantages over some of the methods in vogue. It takes less concrete than the old method of filling under and around wooden ties. It places the concrete and the strength where it is most needed, and, when properly put in, it is certainly permanent, and the roadbed will easily outwear two or more sets of rails under heavy traffic. The rail can be changed without disturbing the roadbed in the least, if proper provisions have been made in the steel ties originally.

On one section of similar track construction, known to the writer, not the slightest sign of any motion could be detected after 3 years' operation, and it is reported to be in as good condition as the day it was built.

The writer trusts that the foregoing brief description may prove of interest to members of this society and bring out some discussion on work of this class, concerning which very little has appeared in the technical press.

The work was done by the Springfield Traction Company, owned and operated by the Federal Light and Traction Company, of New York, and was executed under the general direction of Mr. W. A. Haller, chief engineer, the writer being in immediate and full charge of all construction matters at Springfield, Mo.

COST OF PUMPING WATER.

The following costs of pumping water by steam power and by electric power are abstracted from a letter written to Municipal Engineering by Mr. William Plattner, consulting engineer of North Attleboro, Mass.

Electricity in the waterworks has now been used for more than fifteen years, and the electrically driven pump has taken a permanent place among the steam driven machinery.

Like all other machinery in waterworks or elsewhere, the electric pump has its limitations. There are situations, however, and they are very numerous in waterworks pumping, where the electric pump is not only a great convenience but a profitable investment. In any power or pumping device, the use of electricity is a question of service, cost of power and investment charge. Conditions in different localities differ, and no two installations are likely to be the same, viz.: pressure (fire and domestic), hours of pumping (day or night), capacity of stand pipes or reservoirs, number of water consumers (flat rate or metered), total head, including suction, discharge, friction, etc.

Here are a few towns that purchased electricity for pumping water, also the price paid per kilowatt hour:

Lincoln, Ill., population 8,000, rate 5 cents to 2 cents per kw. hr.

Dover, N.H., population 13,000, rate 2 cents per kw. hr.

Norwood, Mass., population 9,000, rate 1.6 cents per kw. hr.

Cheboygan, Mich., population 6,000, rate $26.50 per h.p. per year.

Other towns pumping water with electrically driven pumps are as follows: Lima, Ohio; DeKalb, Ill.; Maywood, Ill.; Grand Haven, Mich.; Rockford, Ill.; East Douglas, Mass.; Dudley, Mass.; Harvey, Ill.; Lagrange, Ill.; Blue Island, Ill.; Holland, Mich.; North Chelmsford, Mass.; Uxbridge, Mass.; Webster, Mass.

A comparison as to cost of pumping water, electricity vs. steam, follows. This is for a town of 4,500 people in New England, 200,000 gallons of water pumped per day or 73,000,000 gallons per year. Water is pumped to reservoir from driven wells, pressure 62 pounds.

By Electric Power.

Cost of Plant.

Brick pumping station, 20 x 20 ft.	$ 800.00
Grading, road, fences, etc.	150.00
One 5½ x 8-inch double acting, triplex pump, capacity 220 gallons per minute, in place on foundations, with all measuring appurtenances, including sand and air chamber, and independent pump for renewing the latter, connected with one 20 h.p. electric motor	1,835.00
	$2,785.00

Annual Expenses.

Interest on $2,785.00 at 4 per cent.	$ 111.40
Depreciation on pumping station, $800.00, at 2½ per cent.	20.00
Depreciation on pumping plant, $1,835.00 at 5 per cent.	91.75
Electric current purchased, 60,833 kw. hrs. at 3 cents	1,824.99
Oil, waste, repairs	50.00
Attendance, one-eighth of one man's time	105.00
	$2,203.14

By Steam Power.

Cost of Plant.

Brick pumping station, chimney, coal room	$6,300.00
Grading, road, fences, etc.	250.00
One 9 x 18 x 18½ x 12 duplex compound condensing pumping engine, capacity 220 gallons per minute, set in place, with all necessary appurtenances, connected with one 90 h.p. horizontal return tubular boiler complete in brick setting	4,730.00
	$11,300.00

Annual Expenses.

Interest on $11,300.00 at 4 per cent.	$ 452.00
Depreciation on pumping station, $6,300.00, at 2½ per cent.	157.50
Depreciation on pumping plant, $4,750.00, at 3⅓ per cent.	158.33
Boiler insurance	21.00
342 tons coal at $4.75 per net ton	1,624.00
Oil, waste, repairs, etc.	75.00
Attendance, one-half of one man's time	420.00
	$2,908.33

SOUTHERN VANCOUVER ISLAND

The area described in a report to the department of mines, Ottawa, by Mr. C. H. Clapp, includes that part of Vancouver Island which is south of the Alberni-Nanaimo road, and east of the Alberni canal and Barkley Sound; and also includes Saltspring Island, and several smaller islands off the east coast of Vancouver Island, in Haro Straits. This area is approximately 4,000 square miles.

Much of the southeastern and eastern part of the region is accessible by road. In the vicinity of Victoria, on the Saanich Peninsula, and along the east coast north of Cowichan Bay, the country is well settled, and there are many good roads. Main roads extend from Victoria west to East Sooke and Jordan River, and northwest by way of Sooke and Shawinigan Lakes to Duncan. There is a stage road from Duncan to Cowichan Lake, and another from Nanaimo to Alberni. There are two railroads in the area, the Victoria and Sydney, and the Esquimalt and Nanaimo. The former is located on the Saanich Peninsula, while the latter follows the east coast as far north as Nanoose. At the present time an extension is being built across the island to Alberni. Other extensions and new railroads and tramways are projected, to open up the interior of the island.

At present the inlets and lakes, a few of the rivers, and the Cowichan Lake and Alberni roads furnish ready access to the interior of the island, and no very long packing trips need be made. Such trips at the present time must be made without the aid of pack animals, as the trails are not numerous, and with two or three exceptions are suitable only for men. Even these trails, when well located and cleared of brush, are of the greatest assistance, for on them seven or eight miles may be readily travelled in a day by one carrying a heavy pack; while without a trail three miles is often the limit which it is possible to travel in a day, with the hardest sort of muscular work. The establishment of more trails is, therefore, of the greatest importance, and would fill a most urgent need.

A large part of the shore may be safely traversed in a small boat. Coasting steamers run between Victoria and ports on both the east and west coasts.

The mineral resources of southern Vancouver Island include deposits valuable, or possibly valuable, for gold, copper iron, fuels, fluxes, lime, cement pigment, clay, sand and gravel and stone. Coal has been the chief source of mineral wealth, and copper and some gold have been commercially produced. Lime, cement, clay, sand, gravel, and crushed stone as well as coal are being produced at present.

Gold is found in the gravels of a large number of the streams of southern Vancouver Island, but with two or three exceptions, the principal deposits all occur in the streams which drain the area underlain by the Leech River slates and have been derived from very low grade quartz veins in that formation. The gold-bearing gravels [illegible] Where accumulations of gravel at the old mouth of Lost River and near the mouth of [illegible]

The copper deposits of southern Vancouver Island are [illegible] zones with accompanying quartz veins, under which is the [illegible] Mount Sicker. The contact deposits, which are developed chiefly in metamorphic limestones near their contacts with intrusive igneous rocks, are the more numerous. They are, as a rule, small, irregular, and of low grade, but some of them are of considerable economic interest. The deposits occurring in shear zones are of little importance, with the exception of the special Sooke type, which is of great prospective interest. The Tyee deposit, now largely worked out, is the only deposit from which there has been a commercial production.

The iron ore deposits are of four types, contact deposits, impregnated schists, replacement or segregation deposits in the Sooke gabbro, and bog ore deposits. The contact deposits are by far the most important; and consist of bodies of magnetite, which have been formed in the metamorphosed Nitinat limestones, near the intrusive Beale diorite. The bodies are large, and low in phosphorus, but high in sulphur. The chief deposits occur in the valleys of Gordan River and its tributary, Bugaboo Creek. The impregnated schists occur in the Sicker series. The mineral-bearing rocks are dark red, jaspery schists, with 10 to 15 per cent. of magnetite. Since the magnetite can be easily concentrated they are of prospective importance. The other two types are apparently of no value.

Coal is the source of a very important industry on the east coast; the coal being obtained near the base of the Nanaimo formation in the Comox basin, and in the northern part of the Nanaimo basin, from 600 to 1,500 feet above the base. These coal deposits have not been examined during the present investigation. Coal of commercial value is apparently absent from the other basins of the Cowichan group, and is almost certainly absent from the Tertiary sediments of the west coast. These sediments have also been prospected for oil, but the conditions for the accumulation of oil do not seem to be favorable.

The crystalline limestones of the Nitinat and Sutton formations furnish excellent and ample material for flux, and for the manufacture of lime and cement. Cement is manufactured in the southeastern part of the island by the Vancouver Portland Cement Company, and lime is burned by several manufacturers also in the southeastern portion of the island.

A bog deposit of yellow ochreous clay in the Sooke district is a possible source of material for a base for colored paints.

There are two types of clay deposits in southern Vancouver Island, the shales of the Nanaimo formation and the clays of the stratified superficial deposits. The greater part of the shales of the Nanaimo formation are sandy and impure, but associated with the coal in the Nanaimo and Comox basins are thin, lens-like beds of clay-shale. This shale is mined by the coal companies and used by the British Columbia Pottery Company at Victoria, where it is mixed with the clays of the superficial deposits, for the manufacturer chiefly of sewer pipe. The clays of the stratified superficial deposits are used for the manufacture of common bricks and drain tiles, at Victoria, Sidney, Sidney Island, and Somenos.

Sand and gravel are also obtained from the stratified, superficial deposits of southeastern Vancouver Island.

The fractured and sheared character of the rocks renders most of them unfit for building stones. In rare instances the marbles may be of value, and some of the dark granitic [illegible] exposed near Alberni canal would doubtless make good building stone. The sandstones of the Cowichan group, especially of the Nanaimo and Comox basins, offer excellent material for stone of that kind.

The traps, especially those of the Metchosin volcanics, offer abundant material for an excellent quality of crushed stone. The Metchosin volcanics are quarried at Albert head, in Esquimalt district, by the British Columbia Trap Rock Company.

CONCRETE SIDEWALKS.

In the building of concrete sidewalks a wide diversity of opinion exists among engineers as to the foundation to be used. A few years ago it was quite customary among municipal engineers to provide in the specifications for the laying of drain tile under the centre of the walk. This drain tile was very often laid when there was no necessity and without outlet, with the consequent result, the drains filled with water and very often froze in the winter. In many of the towns and cities throughout Canada may be noted sidewalks with a longitudinal crack running along them. This in nearly all cases was the result of the water freezing in the drain tile. The drain tile is not very often used or called for in specifications at the present time, but the question of foundation is still an important one. The usual specifications call for a foundation base of several inches of cinders or gravel. The object of this base is to provide a foundation of porous material to furnish proper drainage. It stands to reason that when the sidewalk is laid upon a naturally drained soil, such as gravel or sand, this porous base is, therefore, unnecessary. If the sidewalk is built on clay, the base of cinders or gravel may have the same effect as the drain tile mentioned above, particularly if no way is provided to remove the water that will collect in the porous base. To the engineer who has had some experience in laying sidewalks, it will be appreciated how hard it is to make the contractor provide drainage for the foundation.

We believe that in most cases the best results will be secured by omitting the porous base and by placing the sidewalk on the bare earth. Information received from a number of municipal engineers recently leads us to think that this is being done in many of our towns and cities now. The results appear in all cases to be as favorable, or more favorable, than with the use of a base. The omission of the clause in the specification calling for a foundation of cinders or gravel will usually be justified, and will result in a considerable saving.

◆

WINNIPEG WATER.

Winnipeg has reached the point where some decisive action must be taken with regard to its water supply. The chief available sources of supply, as pointed out in the recent report by Prof. Slichter, are the Winnipeg River, the Poplar Springs, the Crystal Springs, artesian wells and Shoal Lake. Shoal Lake, the source recommended in the report, is about ninety miles distant from the eastern extremity of the city, in the Lake of the Woods district. The Provincial Board of Health maintains that the water supply of the city should be of an abundant and pure character, and derived from a visible source. The Commission of 1907, who reported on the water supply for Winnipeg, recommended Winnipeg River as a source of supply, but they stated that Shoal Lake was their ideal. They thought, however, that such a project at that time was too expensive. City Engineer Ruttan, in his report on Prof. Slichter's recommendations, states that hitherto the great cost of a supply from Shoal Lake has been considered an insurmountable objection. He adds that the quality of Shoal Lake water leaves nothing to be desired, and it is to be regretted that the engineering data available is not sufficient to enable an accurate estimate of the cost of the project to be made. He suggests that steps be taken to have a thorough and accurate survey of the Shoal Lake project made, so that all the points now in doubt, including the cost, may be determined.

It is clear, therefore, that from every standpoint Shoal Lake water is the best for the city, and it comes down to a question of cost. It is to be hoped that after a thorough engineering investigation Winnipeg will be able to secure their water supply from this source.

◆

THE POLLUTION OF WATERS.

Last week we noted in the editorial columns that the International Joint Commission has been instructed by the government of the United States and Canada to investigate the question of pollution of boundary waters. The closing session of the Canadian Public Health Association Congress, held last week in Toronto, was marked by a strong resolution adopted by the executive council, taking a firm stand on the question of the pollution of waters. The resolution states:—

"That a committee of members be nominated to draw up a memorial to be presented to the Dominion Parliament, as follows:—

"That it is against the interests of the public health that raw, untreated sewage be permitted to discharge into waters which are used as sources of water supply.

"That it is the conviction of the Canadian Public Health Association that an Act of Parliament regulating the pollution of streams and lakes is required in order to strengthen the action of provincial authorities in this matter.

"That the committee appointed be given power to draw up the said memorial and present parliament all available evidence and data bearing upon the matter of prevention of pollution of waters which may be or are used as sources of water supply."

Last year at the annual meeting of the Canadian Society of Civil Engineers a similar resolution was passed and a committee appointed to approach the Dominion government on the same question. Resolutions like the above, when backed by such powerful organizations, should be instrumental in drawing the attention of the Dominion authorities to the necessity for some immediate action towards the regulation of the pollution of streams and lakes throughout Canada.

In one of the addresses delivered before the American Public Health Association, held in Washington last week, the statement was made that so much damage does sewage do to the water in the vicinity of large cities that Lake Michigan is more or less polluted to a distance of several miles from shore, at times heavily so.

The speaker added that the intake pipes supplying drinking water for the towns along the lake shore should be carried out from twelve to fifteen miles from shore, and sewage disposal plants should be provided in the cities discharging sewage into the lake or rivers emptying into it.

An Act of Parliament regulating the pollution of streams and lakes would certainly aid in strengthening the hands of the provincial authorities in preventing raw, untreated sewage being discharged into waters which are used as sources of water supply. The public are gradually being impressed with the danger of polluting them with a haphazard system of disposal. Modern technical conditions demand the abandonment of primitive methods and the utilization of scientific methods of treating sewage before it is allowed to enter the streams and sources of water supply.

ROAD IMPROVEMENTS.

The second annual report of the Road Board of Great Britain affords some interesting data concerning road improvement. The report shows that about two and a quarter million dollars has been expended upon the improvement of road crusts, and about two hundred and seventy-five thousand dollars upon road widening and improvement of curves and corners. In certain criticisms of the work of the Road Board which have been made in Great Britain, the predominating note appears to be the slowness made in the employment of tar-spreading. It is stated that there can be no two opinions that both in the case of the dusty roads of last summer and the wet roads of the present year the judicious use of tar has worked wonders. It would be difficult, even in the case of a variable and treacherous climate like that of England, to find two summers more unlike one another than those of this year and last year, but both for the crumbling roads of 1911 and for the sodden roads of 1912 the tar has been found to give excellent results. This is more especially the case with the soft roads, intended for rural traffic, made with local sandstone, as in Surrey, for instance, or with some of the more porous varieties of limestone. On certain of the Surrey roads tarred three years ago, which received a light coating of tar again this spring, there is surprisingy little wear perceptible, whereas on roads of the same character in the immediate vicinity where no tar was spread the rain is running in streamlets along the channels worn during last summer in the soft metalling, the surface having been pounded into dust and distributed over the hedges and gardens. Not only does the tarred road behave better under the elastic tire, but it certainly throws off the wet and keeps sound much longer than the untreated macadam.

Where tar or heavy oils have been used on the road surfaces in this country, it has been almost universally successful. It is surprising the improvement that will result from even one application, and it is certain that the use of such surfacings will widely increase.

AMERICAN PIG-IRON COSTS.

During a recent discussion between representatives of iron mining companies and Ohio taxation officials of Cleveland, Messrs. Hanna and Company presented the following statement as to the cost of making a ton of pig iron in the Valley:

Iron ore, 2 tons	at $2.75	$5.50
Freight to Valley	" 0.56	1.12
Coke, 1.2 tons	" 2.25	2.70
Freight from Connellsville	" 1.35	1.62
Limestone, .5 ton	" 0.65	0.325
Freight on limestone	" 0.35	0.175
Cost of raw material		$11.44
Conversion cost at furnace		2.00
Cost of one ton of pig iron		$13.44

With basic, foundry and malleable iron selling as low as [illegible], the selling price was less than the cost as given.

SPECIAL TRACKWORK FOR CITY ELECTRIC RAILWAYS.

The following is abstracted from an article by Mr. W. E. Turner, published in the August issue of Applied Science.

In the construction of electric railways in cities, and especially in paved streets, the special track layouts constitute one of the most important items to be decided on, ordered, constructed and maintained by the engineering department. The high first cost, high maintenance, and quick depreciation of even the best layouts, make them an item of great importance to the company.

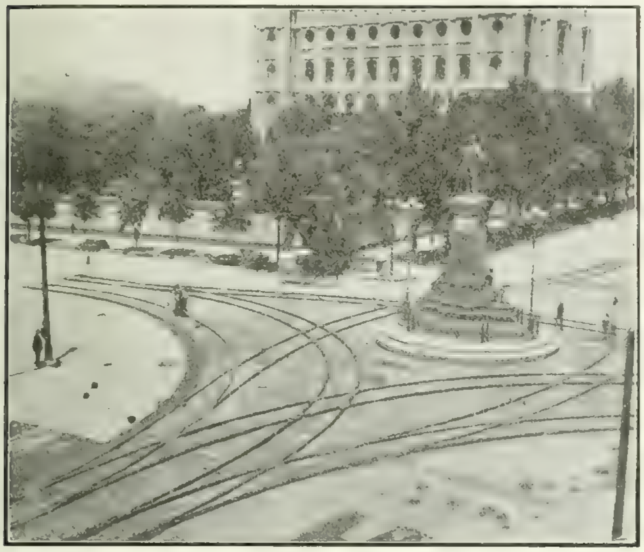

Fig. 1.

As a general rule the street railway company does not manufacture its own special work and it is not the intention of this article to deal with the manufacture of specials, but rather to present a few of the most important considerations for the engineer of the railway and at the same time to explain terms and conditions which may not be familiar to those who have not encountered much special work.

A special layout is a combination of switches, mates, frogs, crossings, and curves, arranged to make connections between different tracks. In its simplest form it is a plain ninety degree crossing of two tracks, and in its more complex phases it becomes a very intricate network of steel.

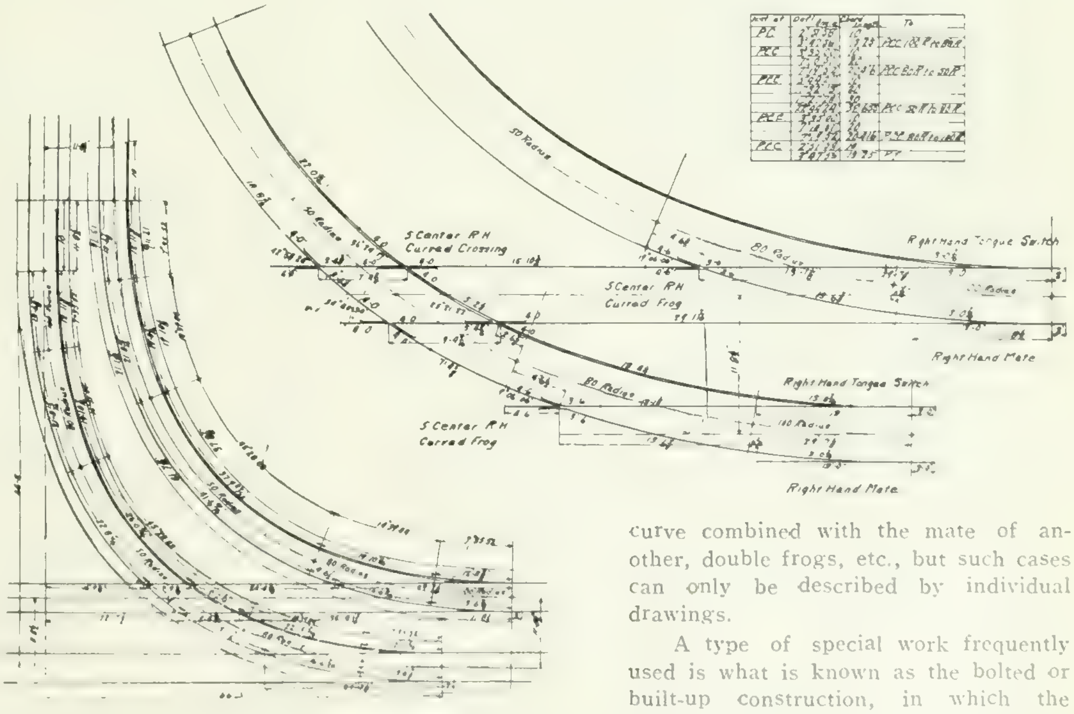

Fig. 2.

Fig. 1 shows a sample layout of average complication for a business district intersection. This particular instance is what is known as "the Brigham Young Layout," surrounding the famous statute of Brigham Young at the corner of South Temple and Main Streets in Salt Lake City. In the background may be seen the Mormon temple and tabernacle, the latter having the curved roof. This layout is on the tracks of the Utah Light and Railway Company, and the other illustrations and descriptions are drawn largely from this company's standard practice. It may be interesting to note that the Brigham Young layout cost about $13,000, complete, in place, and repaved.

In Fig. 2, showing a five-centre curve, may be found the names of the most commonly used pieces in track layouts. It will be noticed that in all cases tongue switches and mates are referred to instead of split switches, which are used entirely on steam roads, but very seldom on city electric lines. There are right and left hand switches, those shown on Fig. 2 being known as right hand because the curve turns to the right when entering it from the switch. There are also right and left hand curved frogs and crossings.

A cross-over is a connection between two parallel tracks as shown in Fig. 3. The switches and mates are the same as those shown in Fig. 2, but in this case we have straight frogs and it is not necessary to carry them in "rights" and "lefts." Right hand cross-overs are always preferable where the traffic takes the right side of the street on account of avoiding a "facing switch," that is, one in which the point of the tongue faces the approaching car. Cars must stop or run very slowly when passing a facing switch. A turnout is similar to a cross-over except that the second track ends at the turnout instead of going right through. Sometimes spring switches are convenient at turnouts. For instance, if all the traffic going south takes the turnout, and all going north takes the through track, the switch may have a spring holding the tongue in position for the turnout. It is evident that cars going north will enter the switch from the rear end and spring it out of the way as they pass.

Besides the above commonly used "specials," there is an infinite number of odd pieces, such as the frog of one curve combined with the mate of another, double frogs, etc., but such cases can only be described by individual drawings.

A type of special work frequently used is what is known as the bolted or built-up construction, in which the specials are built up of pieces of rail, planed off to fit together, bent for wings and curves, and bolted through steel bars and cast steel fillers. Practically all steam road specials are made in this way, and being the least expensive form of construction, the build-up specials are adaptable to electric roads in unpaved streets where traffic is light. They are used extensively for steam and electric crossings.

A more rigid form of construction is the cast iron body which, in the molten state unites so closely with the rail components as to form practically a solid mass. The cast body has usually the hardened renewable centre. The centre plate is hardend by patented and more or less secret processes, a very satisfactory combination being manganese steel, which will wear probably four times as long as ordinary rail steel.

The most substantial, and incidentally the most expensive, specials are simply solid castings with no rolled sections, but with the ends cast in the form of rolled sections to join abutting tracks. Such castings are used for very complicated pieces, and for points of heavy traffic, such as important steam road crossings in pavement, in which case the whole crossing is sometimes cast solid or hardened steel. This form is quite expensive to use.

Hardened steel rails may be obtained for use on curves where the wear is very excessive. Titanium alloy steel has been recently introduced for this purpose.

In deciding what layouts are necessary for any particular system, the first consideration is, of course, the traffic, that is, the regular car routes and special car routes for such purposes as getting in and out from barns, packing cars for resorts or circuses, fair day routes, etc. The next matter of importance is the geographical situation—width of streets, location of curbs, distance between track centres, and possible obstructions such as poles.

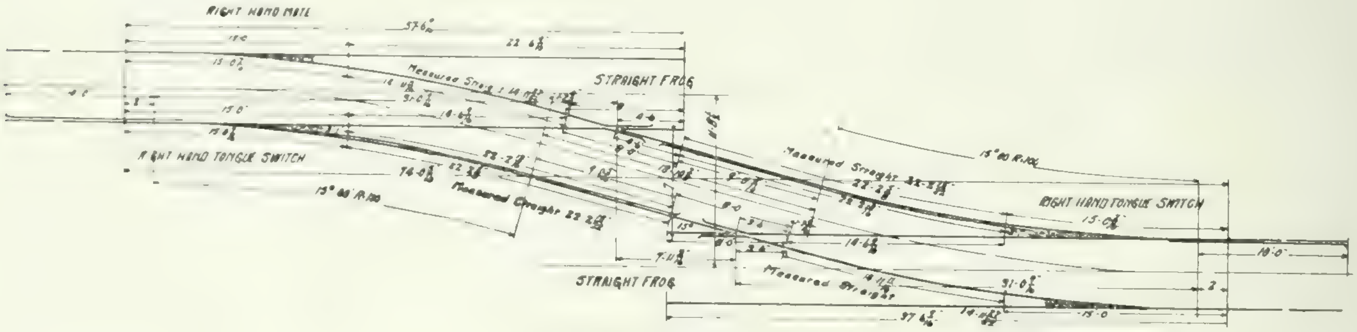
At the same time it is well to investigate whether cars can pass each other on curves. This can most conveniently be done by drawing up to scale a double track curve, such as shown in Fig. 2, and drawing on a separate piece of tracing linen, to the same scale, the longest car likely to be used, with the centres of both pivot plates marked. The drawing of the car is cut out and placed on the curve. By following the centre line of the track with the two pivot points, a clearance curve may be traced where the end of the car [illegible].

Besides these fixed conditions to be encountered, the engineer must himself fix a condition to make every possible piece of special work conform with certain standards. For instance, there is no reason why practically every switch and mate on the system should not be made for a 100-foot radius curve. The greatest advantage in conforming to standard pieces is, of course, interchangeability and keeping [illegible] which may be [illegible] for repairs, and other good advantages are the reduction of office work on [illegible] [illegible] keeping stock, in the field in laying out work, and in the shop and track departments by [illegible] with which the men are familiar. Track should be standardized by using only one or two standard rail sections. Throughout the system [illegible] of 65-pound A. S. C. E. [illegible] it is generally better to employ compromise joints to the special work than to order specials in odd sections.

If all double tracks are maintained at a fixed distance between centres, it will be a great step towards holding to standard special work. That will at least provide that all crossovers and turnouts may be standardized and will insure the same advantage to curves to a very large extent.

In the design of curves the first consideration is to fit the ground and clear obstructions, the second to use standard pieces in every place possible, and the third to get the greatest available radius of curvature. As the most of the street intersections will probably be of similar design, a standard curve such as shown in Fig. 2 may be employed for all such places. In Salt Lake City, there are two standard curves in use, viz., the five-centre curve, which is shown in Fig. 2, for narrow streets, and a three-centre curve for the broader streets. The least radius in the three-centre curve is 66 feet 7 inches, and in the five-centre curve, 50 feet.

A compound curve, such as shown in Fig. 2, facilitates sharp curves on corners, permits the standard 100-foot switch and mate, and swings the car gradually from large to smaller radii. Its use is to be preferred to a plain curve. It is easily laid out in the field by reference to the table in the corner. Some of the large steel companies recommend spirals at the entrance to curves. Instead of running over a 100-foot radius and an 80-foot radius to get to the central 50-foot curve, they would start with a 100-foot radius and spiral around by an infinite series of decreasing radii to reach the 50-foot curve.



Standard Right Hand Crossover

Fig. 3.

In connection with the least radius of curvature practicable for general use it is a matter impossible of accurate calculation and one upon which authorities differ. Curves of as small as 35-foot radius, and possibly less, are in use, but it is conservative practice to establish a limit at 50 feet. On a 50-foot curve the rail wear is very excessive, wheel depreciation is high, and the load on line and motors is severe.

Referring again to the necessity of standardizing all pieces, a list is given of the specials usually carried in the Utah Light and Railway Company's stock, as an illustration of the number of pieces necessary even when all work is standardized. The 80-pound specials are high tee rail for use in the commercial district, and the 65-pound A. S. C. E. for use elsewhere. It will be noticed that frogs are not referred to by number according to steam road practice, as that system is not applicable to right and left hand curved frogs.

Besides this list there are some odd pieces left from previous administrations. The above are all of the manganese centre, cast body type. Steam road crossings are all special and ordered as required and are mostly of the bolted construction bought on a tonnage basis.

As the listed specials range in value from $50 to $400, they represent a considerable investment. The stock is piled in the material yard along tracks. The pieces are marked 5CL, 3CR, etc., and they are handled with a light derrick car.

List of Specials Carried in Stock—U. L. & Ry. Company.

	Frogs	Curved Crossings	
80lb R.H. switches	80lb R.H. 5C	80lb R.H. 5C	80lb straight 15° frogs
80lb L.H. switches	80lb L.H. 5C	80lb L.H. 5C	80lb square crossings
80lb R.H. mates	80lb R.H. 3C	80lb R.H. 3C	
80lb L.H. mates	80lb L.H. 3C	80lb L.H. 3C	
65lb R.H. switches	65lb R.H. 5C	65lb R.H. 5C	65lb straight frogs
65lb L.H. switches	65lb L.H. 5C	65lb L.H. 5C	65lb square crossings
65lb R.H. mates	65lb R.H. 3C	65lb R.H. 3C	
65lb L.H. mates	65lb L.H. 3C	65lb L.H. 3C	

Note. R.H. and L.H. denote right and left hand, respectively.

Drawings should be made of all standard layouts showing distinctly the track alignment, gauges, length of wings required, and in ordering the specials the above drawings may be sent to bidders without any detailed drawings of the construction, and without any rail lengths, frog angles, or other details which may be readily worked out from the data given. The steel companies always re-calculate these items and use one of their standard forms of construction on the specials. An exception is in the bolted or built-up construction for which it is well to have a standard drawing, showing type of construction preferred, in detail but leaving out angles, radii, wings, rail sections, etc., which must be filled in for each individual case on a separate skeleton drawing.

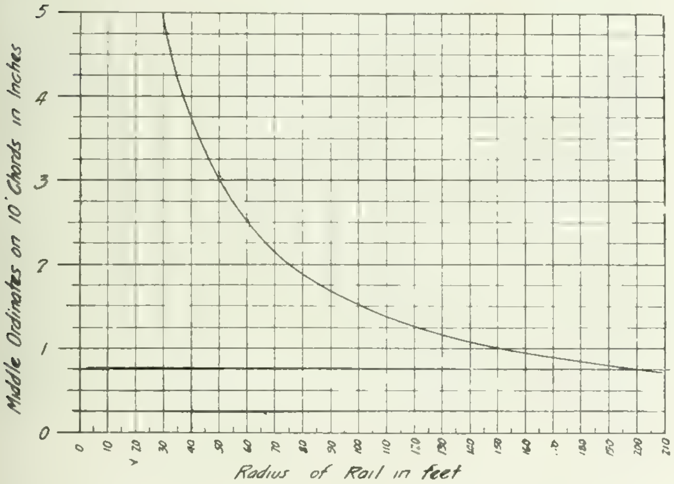


Fig. 4.—Middle Ordinate Curve for Rail Bending.

An order for specials should cover the points to be found in the following sample order.

Sample Order.—Three crossings, right hand, standard 5-centre curve, hardened steel renewable centre construction, C. I. body, for use with 7-in. 80-pound rail, Lorain section No. 335 with 1-in. by 5½-in. bar guard plate as shown on drawing, No. X. Drilling for track bolt, 3-in. 6-in. 1⅛-in. holes; for bonds 31-32-in. holes 6 in. from ends, all 3¼ in. above base of rail. See drawing No. Y for drilling. General layout on drawing No. Z (see Fig. 2). (It is sometimes advisable to refer to a catalogue number for type of construction.) All the drawings mentioned may be on the same or different sheets.

Whole layouts may be ordered complete from the steel companies and for complicated layouts it is a good idea to have them made up completely in the same shop, and every piece marked according to blue print. For instance, the Brigham Young layout (Fig. 1) was ordered complete and is all made of guard rail section.

It is customary to make up all simple layouts which require only the standard stock specials, in the railway company's shop. For this purpose, besides having access to a blacksmith shop, there should be a rail bender, a fairly heavy drill press, a metal saw and saw sharpener. The track shop should be convenient to a vacant space large enough to fit together one or more layouts before taking them to the work.

Layouts are staked out with a transit at the shops and in the field. (See transit notes on Fig. 2). For all curves which are not standard the following information is supplied by the engineering department for use of field and shop men; all data necessary for the exact location of track centres such as the P. C., radius and central angle of each curve, the distance between track centres and lengths of tangents. The following details more particularly for the shop men: size of rail, lengths of specials, location of switches, mates and frogs from point of curvature, lengths of each piece of rail measured straight before bending and the middle ordinate of each curved rail on, for example, a 10-foot chord.

Two points might be noted in connection with this, first, that the description of curves by degree of curvature is not convenient when the radius is small, and second, that drawings or measurements, showing the location of the points of frogs or crossings, refer to the intersection of the two gauge lines and need not necessarily coincide with any actual point.

Fig. 4 is a curve showing middle ordinates on a 10-foot chord for different radii of bent rails. For very sharp curves the middle ordinate is different for the outer and inner rail. This curve is derived from the very simple formula—

Middle ordinate $= R - \sqrt{(R + \frac{1}{2}C)(R - \frac{1}{2}C)}$ where R = radius in feet of the bent rail, and C = the chord length in feet.

In the case first considered, the length of chord is 10 feet.

◆

A LARGE CONVERTER.

What is declared to be the largest converter in existence has been blown in at the Boston and Montana smelter at Great Falls, and officers of the Anaconda company are watching its operations with much interest, as the result will decide whether such a monster furnace can really effect a saving in smelting operations. President B. B. Thayer, of the Anaconda company, witnessed the start of the new converter, which will take approximately 50 tons of molten metal. It is of the upright type, to which the Anaconda company has always adhered, while others have tried the barrel-shaped converter. The bearings in the new converter weigh 13 tons each, and when it is full of metal the whole weight is approximately 300 tons. When compared with the former types in use those familiar with the smelting business will recognize the tremendous increase in size is represents. It has a diameter of 20 ft., while those in former use were 12 ft. The wind box has a height of 7 ft. The converter proper, not including the cast iron bearings and gears, weighs 65 tons, and 130 tons of brick were used in the lining. So far the converter has worked satisfactorily. Concerning the company's plans for rebuilding the Great Falls smelter, President Thayer said the contracts for the steel had been signed, and would be delivered not later than the middle of November. The work of reconstruction will then proceed as rapidly as possible.

DEODORIZING SEWER AIR AT WINNIPEG.

A sewer ventilation test, covering a period of three months, was made at Winnipeg, Canada, during 1910 to determine the efficiency of 10 Beeman sewer deodorizing machines located in manholes. Each machine consists of a reservoir containing wood alcohol, the fumes from which impinge upon a platinized porcelain disc about 1½ inches in diameter. The disc is first heated to cherry redness and remains incandescent as long as the alcohol fumes are supplied to it. The combustion of the alcohol fumes produces formalin in sufficient quantities to deodorize the sewer air when it emerges from the manhole. The cost of operation, per day, according to a report by Col. H. N. Ruttan, city engineer of Winnipeg, ranges from 9 to 18 cents for each machine, not including capital charges. Since these tests were made the large burners on some of the machines were replaced by smaller burners with a consequent reduction in the consumption of alcohol and cost.

Operation and Cost of Sewer Deodorizing Machines at Winnipeg, November 1, 1910-January 31, 1911.

[illegible]

A report by Dr. J. H. Leeming, city bacteriologist, indicated that no bacteria were found in the sewer air, either before or after passing through the machine, and that the formalin is not in sufficient quantities, nor in contact with the air a sufficient length of time, to have any effect upon bacteria if they did exist in the sewer air.

From the tests at Winnipeg Colonel Ruttan draws the following conclusions: (1) The machines will deodorize sewer air; (2) they will not destroy bacteria nor will they have any effect in preventing them from emerging from the manholes, assuming that they exist in the sewer air; (3) [illegible] per day; (4) the number of manholes in the city sewer system is approximately [illegible] and the number of deodorizing machines should not be less than one in every third manhole.

[illegible]

[illegible]

coming from the abattoirs, but at the end of November these burners were removed and the ordinary burners substituted, and have been working more satisfactorily since.

The city of Winnipeg entered into a contract for 50 more of the deodorizing machines; they were supplied by the International Sanitary Company, Limited, of Winnipeg, which has submitted the following estimate of the cost of yearly operation of the Beeman deodorizers on the basis of 800 machines being operated 12 months in the year: 800 machines at $75, $60,000, or a yearly interest of $2,400; cost of alcohol, 800 machines using 1 gal. at 62½ cents every 9 days, $20,000; cost of attendance, 1 man, $900; cost of rig and driver, $1,200; cost of wicking and sundries, $100; allowance for extras, $300; total, $24,900 yearly.

To this would have to be added the cost of the machines which, estimating 12 years as the probable life, would give an annual cost of $5,000, making the estimated yearly expense a trifle under $30,000 yearly.

◆

ELECTRO-METALLURGICAL DEVELOPMENTS IN CANADA.

In a paper on this subject read before the American Electrochemical Society, Mr. S. Dushman refers to the copper-nickel deposits in the Sudbury district, and Dr. Haanel's scheme for the magnetic separation of the iron and magnetic nickel from the copper, precious metals and non-magnetic nickel compounds, followed by electric smelting of the iron-nickel portion to form ferro-nickel, and electrolytic treatment of the tailings as is practised at present in dealing with the matte, which process would enable Canada to export finished products instead of matte, as is now done. Referring to the iron ores of Canada, Mr. Dushman points out that Canada has immense iron-ore deposits distributed at widely different points. The deposits in Northern Ontario, in the Ottawa and Gatineau districts, and in Vancouver and Texada Islands are specially noteworthy. Many of these ore deposits are situated in localities where coke for smelting operations has to be imported from Pennsylvania at prohibitive cost. In fact, it is only in the extreme eastern portion of Canada, where the iron ore of Newfoundland can be worked economically with the coal deposits of Cape Breton, that an extensive iron industry has developed. In Ontario and British Columbia coke for metallurgical purposes has to be imported. The deposits are, however, usually situated near some source of water-power that could be developed at low cost. The lack of ores suitable for treatment by the blast furnace has been one of the factors preventing the growth of an iron industry in Ontario. But by the use of electrothermic processes and some method of concentrating the ores, it is quite within the limits of possibility that a much larger iron industry could be developed in Ontario. Recent Government experiments on [illegible] ores from different points in Ontario have demonstrated that first-class Bessemer concentrates (with one exception) can be produced from the crude ore submitted for testing purposes, and it has been [illegible] sulphur, when submitted to a process similar to the Grondal system of briquetting. These briquettes could, of course, be treated in the electric furnace. The combination of concentration and electric furnace [illegible] when it is considered that Ontario contains numerous sources of water-power that could be developed at low cost. Considering the advantages offered by electrothermic processes and their special applicability to Canadian ores, there seems to be no doubt [illegible] future for the electric iron and steel industry in that country.

HOW TO OBTAIN EFFICIENCY FROM PRESSURE FILTERS.*

By H. W. Cowan, C.E.

Before discussing the efficiency of any type of filtering appliance it will be necessary to give a brief resume of what has brought about their evolution.

The first type of filter, consisting of a large prepared bed of sand, was the result of observation of the effects produced on water which had flowed through layers of sand and gravel, giving a clear and crystalline stream as the result.

On putting this into operation, good results were not obtained immediately, but after several days' run the resulting effluent was apparently satisfactory.

The reason for the change was due to the slimy deposit which had formed on the surface of the sand.

This produced a sticky coating round the particles of sand on the surface of the bed to which suspended matter adhered and was retained, in the same way as globules of mercury will run together and become incorporated.

Further experiment showed that with clear waters it took considerable time for the film to form; that only certain rates of flow were permissable, anything higher causing damage to the film, through which break the water flowed as there was little resistance to its passage through the sand at that point. The disturbance set up caused surface currents which further broke up the film, and led to still greater inefficiency.

The rate of flow being determined and maintained, a growth of algae appeared after a time which added to the closeness and strength of the film, allowing a higher rate of flow to be used.

When everything appeared to be satisfactory, after some weeks' operation the water supply showed signs that breaks in the film were present.

These proved to be due to the presence of insect larvae, blood worm tubes having formed in the sand, from which the insect Chironomous on maturity emerged in large numbers, leaving small perforations through which the water flowed at a high rate, producing vibrations which broke up the continuity of the film.

On cleaning the beds, which were an acre in extent, for a volume of two million gallons per twenty-four hours, a repetition of the first troubles in again tuning up the beds before they were effective was experienced.

Regulations being used to determine the rate of flow, and careful examination being made from day to day to show when the beds required cleaning improved the position until it was found that the algoid growth in winter was much slower than in the summer months, calling for varying adjustments to suit seasonal conditions. In short, expert attention had to be given to slow sand filters to be productive of good results.

The disadvantages of this method of filtration had to be overcome, something being required to form the filtering film quickly, positively and evenly, which would operate to the same advantage in summer and winter, the cleaning of which could be simplified so that it might be performed more frequently, before insect ova could be deposited, and allowing of a much higher rate of filtration.

The first results of these conclusions led to the construction of covered filters to prevent varying conditions in summer and in winter, and the aforementioned insect troubles, but the high cost involved, the difficulty in cleaning, the time required for filming, and the slow rate of flow were still to be surmounted.

In overcoming these difficulties America led the way by patenting the first mechanical filter, to be closely followed a few months later by British engineers with other patents of a similar nature, all claiming a rapid rate of flow, simplicity of cleaning, positiveness in filming, and the occupation of a relatively small space.

These filters were shells constructed of wood staves, steel or iron in which the sand was enclosed so that it could not come in contact with contaminating influences, crushed quartz, charcoal, polarite or oxidium, (patented substances) being also used as the media.

Ferrio Oxide was used as a means of forming the film by entangling the colloidal and suspended particles, which fell on the filter bed, forming a felt in which organic and lighter substances were arrested.

Mechanical filters passed the water at a rate of from eighty to one hundred times that of slow sand filters, and immediately came into favor on account of the clarity of their filtrate, and the large saving in space.

They were washed by passing water through from the under side of the filter bed for several minutes, and running the sediment washed out to waste.

At this time the discoveries of Pasteur, Koch, and other scientists, with regard to bacteria as the means of transmitting disease, enabled research work to be conducted with regard to the real impurities of water and not those apparent only to the eye.

The proof that water was the chief agent in carrying disease gave a stimulus to water purification, having in view the elimination of pathogenic germs.

This led to the study of the effect of using ferrio oxide on the water treated by mechanical filters, which showed that iron was left in the water after filtration.

The growth of such organisms as Crenothrix, Cladothrix, Spirophyllum was produced in the water mains, Crenothrix in particular with its sack-like bladders deriving sustenance from the iron present, and filaments discolored with ferruginous matter were produced.

These filaments attached themselves to the pipes, and diminished their carrying capacity about one per cent. yearly, while back pressure and fluctuating flow detached fragments which discolored the water and gave off an unpleasant odor.

Resulting from this alumina sulphate was put into use, and ferrio oxide practically discontinued, the disadvantages of the latter being overcome. Practically all mechanical filters use this as a film producer at the present time.

The use of alumina sulphate produces a white, sticky viscid film (alumina hydrate) which is precipitated when reacting with the lime in the water. This collects suspended matters, and deposits them on the sand bed, having at the same time the property of removing coloring matter from the water treated, by its coagulating action.

The hydrate being absolutely insoluble, no trace of it can be detected in the filter effluent by chemical reaction, even the well-known log wood test failing to show its presence.

The success obtained led to the attempt to use a coagulant in slow sand beds, by first passing water through large coagulating basins, from which it flowed to the filter beds. This has never proved satisfactory owing to the large area of the beds preventing an even deposit on their surface.

Mechanical filters were now subject to more rigorous tests for the elimination of bacteria, and were found to be unsatisfactory owing to the foulness in the filter material not being removed by washing on account of the sticky nature of the film, which a reverse flow could not remove completely.

Attempts to force air through to assist the passage of the wash water were made but while the filter was apparently clean it was really becoming more polluted through its whole bed.

---

* Paper read before the Canadian Public Health Association Congress, Sept. 17th, 1912, Toronto.

When completely contaminated this would break through, showing a high bacteria count at varying periods, preventing continuous efficiency from being obtained and using a large amount of filtered water in the attempt to thoroughly wash the bed.

For these reasons mechanical pressure or closed filters have been looked on with disfavor for domestic supply, and American engineers have, as a body, reverted back to the open type filter, in which the sand is removed from time to time for complete cleansing, and a much lower rate of flow is used.

The excessive rating of pressure filters had much to do with causing American engineers to discontinue their improvement, but in Britain several engineers persisted in their experiments to obtain absolute cleansing, and finally succeeded in making a filter which could be cleansed mechanically.

In this filter the reverse flow was used, while the sand was violently agitated by means of agitators which released the sticky coating from the grains of sand. The power required to operate the washing mechanism, however, was so great that its use was not feasible.

A few years later the introduction of water under pressure through jets in the agitators, caused the sand to be put into such a state of suspense while they were being revolved, that a very trifling amount of power was necessary.

This allowed of continuous efficiencies of ninety-seven per cent. being obtained. A large amount of reagent was consumed which made operating costs prohibitive, and further study led to consideration of the stone germ proof filter invented by Pasteur.

It was felt that if a silica sand could be used which would compress under the water pressure into a temporary stone, allowing a high rate of flow to be obtained and the minimum of coagulant for the reduction of bacteria, that the difficulty would be solved.

Following these lines the modern filter was devised.

As it now stands the pressure filter constructed in Britain represents the highest type of commercial efficiency, more especially since the use of turbines operated by the inflow of water to pump in the coagulant have been devised

With these turbines as the rate of flow varies so does the amount of alum introduced, and the introduction of the alum before the water passes through the turbines enables these motors to thoroughly mix the coagulant so that positive hydration is obtained before the raw water reaches the filters.

Further observations have led to the discovery that the [illegible]

[illegible]

The rate of precipitation or sedimentation under pressure [illegible]

[illegible]

An adequate means of thoroughly agitating the sand should be employed while the washing operations are going on, and the water used should not exceed what is economical.

The best test for effective washing is to occasionally take a sample by removing the manhole and passing a tube into the sand two minutes after washing has been performed.

The sand withdrawn when placed in distilled water should show little or no turbidity, if it has been properly cleansed.

It is important that only a steady acting pump giving a steady flow free from vibrations be used, as jerks or unsteadiness in the flow might cause distortion and breakage of the film.

A means of adding the coagulant should allow of careful adjustment, varying in proportion to the water passing through the system, and such means should provide for the intimate mixing of the alum to ensure complete hydration.

In no case should pressure filters operate at a greater rate than four thousand gallons per square foot of filtration area in the twenty-four hours.

Their effluent should be free from suspended matter and color so that a platinum wire one-twentieth inch in diameter can be discerned at a depth six and one-half feet.

The bacteria count per cubic centimeter capable of growing on agar or gelatine at 18 degrees Centigrade after forty-eight hours incubation should not exceed one hundred whatever the amount present before treatment.

There should be no bacteria typical of sewage present such as bacilli coli, typhosus, enteritidis, no cholera vibrio nor dysentry bacilli in fifty cubic centimeters incubated for forty-eght hours at 20 degrees Centigrade.

No taste or odor should be distinguishable when water is heated to 37 degrees Centigrade.

Water for washing should not exceed two per cent. of the whole supply.

An effective pressure filter will satisfy these requirements besides having the following advantages:

Simplicity in operation.

Economy in operating costs.

Low initial cost.

Not more than two pounds reduction in pressure, in passing through the filters when clean.

They may be affixed direct to the main and pumped through.

They are suitable for extension by the addition of extra units.

They can be removed at little cost to another site, should circumstances require it.

They are continuous in efficiency, with proper washing mechanism.

Occupying small space they can be housed at a low cost.

Being manufactured ready for erection they can be erected rapidly, cheaply, and in any weather.

They can be used for water softening by the addition of simple appliances.

In Britain pressure filters of high efficiency are supplying a population equivalent in this country to four hundred [illegible], large municipalities having found them highly satisfactory.

Dr. Percy Frankland, in an analysis of the supply of Banbury taken from the river Cherwell, found that the bacteria [illegible] per cent., no coli being found in [illegible] cubic centimeters.

The [illegible] reservoir at Buxton, Derbyshire, show certified reductions of [illegible] to 99 per cent.

The town of Shrewsbury drawing water from the river Severn showed that coli could not be detected in less than five hundred cubic centimeters.

Many similar results, showing as high a continuous efficiency as 99.9 per cent. warrant the attention to those interested in public health work in Canada to this type of filter, which, when properly constructed, is the most suitable for the conditions ruling here.

◆

STONE BALLAST.*

Rock ballast should be made from hard, tough, durable trap, flint, or limestone rock, or other hard stone. It should be broken to cubes, the maximum of which will pass through a 2½-in. ring and the minimum will not pass through a 1½-in. ring. The crushed stone should be free from screenings, dirt and rubbish.

Ballast can be handled in side-dump cars with flat bottoms, or in coal cars, but drop-bottom ballast cars will secure very good results. Ballast after being unloaded should be handled with a spreader. The track should be prepared by digging out the old ballast down to the bottom of the ties, and rounded up to ½ in. above the bottom of the ties in the centre. This will keep the ties from running together until the track is filled with stone. This should be leveled off at the ends of the ties.

All decayed ties should be removed and replaced with new ones. Ties should be properly spaced and track put to gauge, and all spikes driven down so that the ties will be tight up to the rail. Then crushed-stone ballast should be unloaded to fill between the ties in the centre of the track. This will help keep the track in line and prevent the ties from bunching. About 8 or 12 inches of stone ballast should be placed under the ties if possible, and a minimum depth of 4 inches should be maintained.

In raising track on a 9-in. raise, the track can be put up in one lift if a large force of men can be secured. Ordinarily the track is put up in two lifts. In raising in one lift the foreman in charge will soon learn how many rail lengths a train of 15 or 20 cars will raise to the required height. The number of rails are counted off and sufficient ballast is unloaded and plowed out. Four men are started making places for jacks. One end of the sight board is placed on the stake, and the board leveled.

Four jacks are used; two being half a rail ahead of the others. The first pair raises the track about half the required height. No tamping is required with these jacks, as the stone runs under the track by its own weight. The second pair of jacks raise the track to the full height. A force of 20 men should follow to tamp, and these should be followed by a foreman and eight men to put the track in perfect line. The first half of the day should be given to raising the track, the balance of the day being devoted to tamping and lining.

Where two lifts are made, the ties should be tamped with shovels their entire length. After the second lift, the ties should be tamped with tamping picks or bars, the tamping extending from ends of ties to 12 inches inside of rail. Particular attention should be paid to tamping under the rail, but the centre of the ties should not be tamped.

In dressing up single track with ballast, the ballast should be filled in at least within one inch of top of ties and sloped from ends of ties. The edge of ballast slope should not be less than 4 feet from gauge line of outside rail.

Double track should be dressed in the same way, the stone in the centre ditch being level with the stone in the track. When the track is bonded for electric signals, it is very desirable that the stone be kept below base of rail. The track, after being raised, should be left from four to six days before dressing.

In handling 600 to 1,000 yards of stone daily and giving track 9 to 12 inches of raise, the force employed largely depends on the amount of traffic handled, and the views of the officials. A force of 40 to 50 men should be used, and a force organized as follows will give excellent results:

1 Chief foreman.
1 Assistant foreman to raise track.
1 Assistant foreman to line track.
2 men flagging.
4 men digging out for jacks.
13 men on jacks (4 digging holes, 8 on jacks, 1 with levelboard).
20 men tamping.
8 men lining.
1 water boy (or more if necessary).

Minority Report.—The size of stone which the majority of the committee recommend is too large for the maintenance of good track. The size should run from 1¾ in. maximum to ½ or ¾ in. minimum.

---

*Abstract of committee report presented at the annual meeting of the Roadmasters and Maintenance-of-Way Association, Buffalo, N.Y., Sept. 10-13.

◆

CANADIAN PACIFIC RAILWAY IN WASHINGTON.

A New York banking house is informed by its Spokane representative that, in order to obtain a water grade from Kingsgate to Grand Forks and also to avoid three mountains, Canadian Pacific will build additional mileage through the northwest part of Washington, and will utilize the lines of the Spokane International, Idaho and Washington Northern and Spokane Falls and Northern. In this way Canadian Pacific will obtain a new freight line which will occupy an important position geographically in that general section of the Northwest.

Canadian Pacific, according to the same information, has secured from the Hill interests the right to use that part of the Spokane Falls and Northern known as the Red Mountain Line, running between Northport and Rossland, and the further extension of the Hill line to Nelson known as the Nelson and Fort Shepard.

At the present time Canadian Pacific has under way the location and surveying of a new freight line from the terminus at Metaline Falls to Waneta at the junction of the Columbia and Pend d'Oreille Rivers. Canadian Pacific, according to plans recently adopted, will operate its freight to Kingsgate over its own line and over the Spokane International to Clagstone Junction, over the Idaho and Washington Northern to Metaline Falls, over the new Canadian Pacific line to Waneta, and thence by way of Spokane Falls and Northern to Marcus, Grand Forks, the Fraser River and the coast. Canadian Pacific and Great Northern recently entered into an agreement to build jointly the line over the Hope Mountains to the Fraser River.

According to Engineer Dibblee, in charge of the location work, a very easy grade between Metaline Falls and the boundary has been secured, and work will be rushed on this section as well as on the projected line from the boundary to Trail, a distance of thirty miles. Between Metaline Falls and the boundary line eleven tunnels will be built. The total length of the line from Metaline Falls to Trail will be forty miles and construction will cost approximately $3,000,000.

THE PURIFICATION OF WATER FROM STANDPOINTS OTHER THAN THE HYGIENIC ASPECT.*

By George W. Fuller.

In addition to hygienic purity, a perfectly satisfactory water supply should be of good appearance as to absence of mud, vegetable stain, grosser microscopic organisms, soluble and suspended iron; and it should also be free of offensive tastes and odors, excessive hardness and abnormal corrosive action on service pipes.

Within certain reasonable limits, depending upon local conditions, all of these characteristics are worth obtaining in a first-class modern water supply. In fact, the standards of "physical and chemical quality" as distinguished from "hygienic or bacterial quality" are steadily growing higher, due to the demands of the consumers for a supply in which there is public confidence and which does away with bottled water and household devices for treating the public supply. Indirectly, this question is related to the public health through the tendency of the public to avoid for drinking purposes a hygienically pure but otherwise unattractive public water supply, and to use well water or bottled water of doubtful bacterial content.

In this paper it is proposed to outline briefly some of the recent developments in America concerning the physical and chemical features of water purification, and to refer incidentally to the historical development of some of the more important steps.

Removal of Mud or Turbidity.

Plain Sedimentation.—Fifteen years ago, or prior to the completion of the Louisville tests in 1897, the clarification of the muddy water which is so characteristic of the majority of American rivers was accomplished but partially, if at all. Plain sedimentation when applied at its best ordinarily removed only 50 to 75 per cent. of the total suspended matter. With basins holding several days' supply, such as those at Washington, Philadelphia, Pittsburg, Louisville, St. Louis, Kansas City, Omaha, etc., the effluent as delivered to the consumers contained for weeks at a time sufficient silt and clay to make it conspicuously muddy. At times the partially settled water contained several hundred parts per million of suspended matter.

Storage Reservoirs and Avoidance of Muddy Water.—In [illegible] [illegible] were large enough to serve as storage reservoirs from which the supply from the river was shut off at periods of very muddy water in the stream. This [illegible] years at Washington, Baltimore, Covington, York and elsewhere. It is expensive and is seldom tried at present. When the river is muddy for a period exceeding the storage capacity of the basin the benefit of the method not only fails, but the consumers [illegible] muddy water for many weeks. [illegible]

Coagulation and Sedimentation.—[illegible] carbonates and bicarbonates of lime and magnesium naturally [illegible]

gelatinous white precipitate of aluminum hydrate. This sticky mass envelopes the tiny particles of clay and also the bacteria, and forms them into particles of a size that subside quite readily. This process, which is in effect a chemical precipitation method, is of considerable assistance in that it provides a fairly efficient means of removing those minute clay particles, perhaps one-tenth of the size of the bacteria, which will not settle by plain subsidence in an indefinite period. When coagulating chemicals, such as sulphate of alumina or sulphate of iron in connection with lime, are added to the water, it is possible to obtain a fairly clear effluent, provided a proper dose of coagulant is used with respect to quantity and quality of turbidity, and further provided that a period of one to two days or more is allowed for the particles of suspended matter to deposite upon the bottom of the basin. This method has been used at quite a number of places and is still in use at St. Louis, Kansas City, Leavenworth, Omaha, Nashville, etc. It is not wholly satisfactory as compared with the results obtained by filtration, as there is no ready way to correct the poor results obtained from an inadequate dose of coagulent and which correction is much more feasible when use is made of a filter plant. This method can scarcely be called for ordinary problems a complete and satisfactory solution of clarifying muddy water, although its favor has been enhanced somewhat recently in conjunction with sterilization processes, such as the application of hypochlorite of lime.

Plain Sand Filtration.—Forty-five years ago sand filtration was substantially an unknown art in America. There were some crude strainers of artificial construction, but they are unworthy of detailed consideration. The art of sand filtration in America dates from about 1867, when the late James P. Kirkwood, C.E., made an extensive tour of the leading European cities and prepared a report for the Water Commission of St. Louis, Mo., detailing the results of his foreign studies. That report has become a classic, not only in America, but also in Europe, as it was translated into German. It exercised much influence in standardizing the European practice of water filtration.

After Mr. Kirkwood's return to America he found by tests with small sand filters that they would not remove the enormous quantity of sand, silt and clay, such as are found in the Mississippi River at St. Louis. On a somewhat larger scale the same conclusion was demonstrated by tests conducted with the Ohio River water in 1884 by the late Charles Hermany at Louisville.

With the advent of the germ theory of disease there was found in America thirty years ago a feeling among engineers that sand filtration was impracticable through inefficiency and great cost for the ordinary American problem. Two or three small plants were built in the early seventies along the Hudson River, particularly at Poughkeepsie and Hudson, but the question of water clarification remained substantially in abeyance until it was pushed forward as an incidental feature of hygienic water purification

It was the work of the Massachusetts State Board of Health, through its tests conducted at the Lawrence Experiment Station and its advocacy at the Lawrence city filter plant in 1892, that marked the beginning of the present period of wide-spread installation of modern filter plants in America. The Merrimac River at Lawrence contains almost no clay, and but little silt other than at rare intervals when the river is in extreme flood. The data from Lawrence, therefore, while applicable for many of the problems in New England, did not offer a solution of the typical American problem of water clarification or of water purification.

Sand filters, when operated at fairly slow rates, say from [illegible] to six million gallons per acre per day, are efficient in removing [illegible] in quite large amounts. Fine clay particles, however, generally pass through the ordinary sand filter, even when operated at rates much lower than what is called standard European practice, namely, 100 millimeters vertical drop per hour, or 2.65 million gallons per acre per day. Experience shows that when the unfiltered water contains for several days at a time more than about 30 to 50 parts per million of fine turbidity, the effluent is liable to suffer from deterioration in quality, not only as to its appearance, but also bacterially.

---

*Paper [illegible] International Congress on Hygiene and Demography, Washington, D.C.

There are some exceptions to the rule, but generally speaking, sand filters outside of the New England States and some points along the Atlantic seaboard have not been successful in treating American river waters, even after they are submitted to prolonged sedimentation. The only sand filter plant along the Mississippi River, for instance, at Rock Island, Ill., was abandoned some years ago, and in its place was built a mechanical filter plant.

Sand Filters Aided by Sedimentation and Coagulation.—In 1898 the writer conducted extensive experiments for the city of Cincinnati, Ohio, upon the clarification and purification of the muddy Ohio River water by sand filtration in conjunction with sedimentation and coagulation. Similar tests were made in 1901 at New Orleans. This method can be made efficient, but it is ordinarily more expensive than when mechanical filters are used in place of sand filters. Local conditions influence the solution of this problem. Successful use of sand filters with coagulation is to be found at Indianapolis, Washington, Poughkeepsie, and some other places. The feature which needs especial care is to see that the floors of coagulated masses are removed from the water with sufficient care so that the surface of the sand bed does not become clogged too quickly. Ordinarily the water should undergo sedimentation for 18 to 24 hours before it reaches the sand beds. This feature adds to the cost of the complete method and in cases where insufficient coagulant is used there is some danger from serious clogging of the sand beds.

Sand Filters and Pre-filters.—At present there are few or no instances where decided exception is taken to the use of coagulants. Experience has shown that it is safe and feasible to use them where there is intelligent management. Local custom and existing works, however, in some instances force a consideration of methods in which no use is made of these very helpful coagulants. This has led to efforts to clarify water by preliminary filters as well as by sedimentation before application to ordinary sand beds. This is the method in use at Philadelphia, Steelton, Wilmington, Albany, Montreal, and some other places. If the river water is not too muddy from fine turbidity it is of considerale aid. The method has decided limitations, however, in that at times of severe flood the percentage removal of suspended matter is least when it should be most in order to prepare the water properly for normal sand filtration.

In several instances coagulation is used in conjunction with some straining device, such as the practice at Steelton, and arrangements of this general order are now being installed at Pittsburg to aid the local sand filter.

Mechanical Filters.—Where coagulants are required, mechanical filters have rapidly come to the front during recent years. They have been installed or have been recommended for use at nearly every plant of considerable size, outside of the New England States, during the past few years. The modern mechanical filter plant is so well known from numerous published articles that no description is necessary here. It is quite different from and materially better than the earlier devices of this general type. The plant of the East Jersey Water Company at Little Falls, N.J., was placed in service in Septemer, 1902. It was the first large plant in practice to embody the technical and engineering features developed from the tests at Louisville, Cincinnati, Pittsburg, etc.

This type of plant ordinarily operates at the rate of about two gallons per square foot per minute. When the water is properly coagulated such filters may satisfactorily perform at rates from 25 to 50 per cent. in excess of this rate. Such devices deliver a water of excellent appearance and under proper supervision they are substantially as efficient as sand filters in securing bacterial removal. These plants have recently been built with concrete tanks and hydraulically operated gate valves to control the operation of the plant, as well as automatic appliances to insure a pro rata application at all times of solutions of chemicals to the varying volume of water to be filtered. Their recent history is closely identified with a succession of mechanical improvements which allow the devices to be operated reliably and economically. The cleaning of the sand layers is done once or twice a day by reversing the flow of water for periods of five minutes or so at a time. While the water is flowing upward through the sand layer the sand is also stirred by compressed air in cases where the water is not applied at sufficient velocity (2 feet vertical rise per minute) to bring about this result.

Mechanical filters have been installed at Little Falls, New Milford, Louisville, Harrisburg, Cincinnati, Columbus, Toledo, New Orleans, and at some 300 smaller plants. This type of filter constitutes the characteristic method now in vogue in America for insuring a well clarified water supply from the ordinary American rivers which are highly charged with silt and clay. Undoubtedly it is the most efficient and economical arrangement for the majority of American water purification problems outside of certain areas along the Atlantic seaboard.

Color Removal.

For many years it has been known that ordinary sand filters will remove from 25 to 35 per cent. of the color or vegetable stain from the applied water. Such results have been obtained at numerous places in New England. It has been the endeavor in solving many American problems to secure filtered water that does not contain more than about 10 parts per million of vegetable stain as measured by the platinum-cobalt standard. This is approximately the dividing line above which the color becomes readily noticeable to the consumer as seen in a glass upon the table and especially in a porcelain bath tub. Where sand filtration will not allow a result as good as or better than this to be obtained, there has been an effort in a number of places to employ coagulants and thus take advantage of the decolorizing effect of sulphate of alumina. This is an important factor which was considered in arriving at the recent determination in New York City to employ coagulation and mechanical filters for the treatment of the present water supply from the Croton watershed supplying the old city of New York. Sulphate of iron and lime do not give a satisfactory color removal, as demonstrated at Toledo and elsewhere.

In some cases intermittent filters as at Ludlow reservoir, Springfield, Mass., have aided in bringing about an unusually high removal of color. This seems to be due in part to an anaerobic decomposition having taken place in the water before its filtration. The color unites with iron in the water and is precipitated upon aeration. Another interesting feature that has been established at the new filter plant at Springfield is that when the coagulant is applied as an overdose to a part of the water to be treated, it is said that the mixture of the entire mass of treated and untreated water is decolorized to a greater extent by the sulphate of alumina than would be the case if the same quantity of coagulant were to be applied at a uniform rate of dosing to the full volume of water delivered to the purification works.

When the water to be treated contains varying high amounts of both mud and color much care is required in adjusting the required dose of coagulant to the composition of the water.

Microscopical Growths.

Some years ago an unusual effort was made to prevent the appearance in water supplies of microscopical growths of algae and other organisms larger than bacteria for the sake of minimizing their influence upon objectionable tastes and odors. In some instances, particularly in Massachusetts with unfiltered supplies, the bottom and sides of impounding reservoirs were stripped so as to obtain in the exposed surface soil only a small quantity of organic matter. This practice has not recently been followed for the large reservoirs for the new water supply of New York City, or elsewhere, particularly if the impounded water is muddy at times. It is considered better to aerate and filter the water to correct the unfavorable influence of these growths rather than to try to prevent them.

Microscopic growths have been killed in a large number of instances in America through the use of copper sulphate and to some extent by the use of hypochlorite of lime. The latter seems to have certain limitations and is not in such general use as copper sulphate.

Filters incidentally serve for the removal of microscopic growths. In some instances certain types of filamentous growths are likely to give trouble due to filter clogging. At Cincinnati experiences of this kind have been encountered and aid has been secured through the application of hypochlorite to the unfiltered water. It is a style of problem that requires special treatment in most cases.

Tastes and Odors.

Many surface waters, particularly those which are not turbid, contain at times objectionable tastes and odors. The latter are sometimes due to growths of organisms themselves. In other cases they are due to the disintegration of the organisms and to the liberation of certain oils which are very penetrating in their nature. Still other objectionable tastes and odors are found in waters that have undergone anaerobic decomposition which causes offensive gases to be liberated.

Aeration is a great help in the removal from water of these properties which produce objectionable tastes and odors. Combined with filtration, either mechanical or sand filters, there is obtained the most practicable method of securing a satisfactory water as to freedom from tastes and odors. It is one of the characteristic features of the new Catskill supply for New York City, and is being carefully [illegible] supply of [illegible]

Iron Removal Plants.

There are half a dozen plants in America, mostly of small size, where ground waters are aerated in order to pre-[illegible] filters. Most of the earlier filters were of the sand filter [illegible]

Water Softening.

[illegible]

found and even in the Great Lakes district the water is much harder than it is along the Atlantic seaboard. The cost of softening very hard water supplies has undoubtedly been a factor in retarding developments along this line. Experience has shown, however, that it is a perfectly feasible matter to soften the western waters if it is so desired.

At Grand Rapids, Mich., a mechanical filter plant is approaching completion that is to be used in conjunction with a softening plant. This plant will remove mud and vegetable color from the Grand River water and reduce its temporary or carbonate hardness by perhaps 50 per cent., so that it will equal what is called locally the "Lake Michigan standard." The total hardness of the softened and filtered water will be approximately 125 parts per million. The reduction in hardness will be effected by lime without soda.

Corrosion of Pipes.

Service pipes, particularly those of galvanized iron or wrought iron, are more liable to corrosion with filtered water than with unfiltered water. In part this is due to the elimination of substances, such as silt and vegetable matter which retard in a physical way the rate of corrosion, and in part it is due to an increase in carbonic acid which in the presence of oxygen is a very prominent factor in influencing the total amount of corrosion, the rate of corrosion and the amount of dissolved iron which may be present in water as drawn from the faucet and is thus the principal feature of unsuitability from the standpoint of iron stains. It is scarcely feasible to remove the oxygen present in water and, in fact, aeration tends materially to increase the oxygen up to the limits of the saturation point of this gas.

Carbonic acid seems to be the principal feature related to the speed amount of corrosion of iron by filtered water. Where coagulants are used there is a corresponding increase in amount of free carbonic acid. This has led some people to consider this feature as quite a draw-back to the use of coagulants. It has been studied recently in New York City from the chemical viewpoint with much thoroughness. The conclusion has been drawn that it is feasible to control the amount of carbonic acid through the proper addition of lime or soda. This feature will be an interesting part of the new Croton filter plant.

With hard waters in the south and west there has been comparatively little or no difficulty as regards corrosion of pipes by filtered water. The problem, therefore, is related more particularly to the soft waters along the Atlantic seaboard.

Speaking generally, water purification as relates to filtration is on a thoroughly well established basis in America. The features that differ most essentially relate to preparatory treatments rather than to material differences in designs either of sand filters or of mechanical filters. The use of chemicals for purposes of coagulation and softening has been studied in the last few years with considerable thoroughness and the problem is one that is so related to [illegible] that each project should be carefully studied on its own merit rather than to attempt to [illegible] the type of works which may be in [illegible]

[illegible] that the successful methods of water purification should receive intelligent [illegible] the case where the type of water calls for the use of coagulating chemicals.

RAILWAY RECEIPTS AND EXPENSES.

As the month of July began a new fiscal year for the railways and also from all indications a period of reviving traffic, it is probable that railway returns will be closely watched, especially during the months of the presidential campaign. But the uninitiated reader who tries from the newspaper reports of earnings and expenses to keep track of the business of the railways has a perplexing task, for in one and the same issue of a newspaper he not infrequently finds statements of earnings and expenses that may refer to different periods separated by weeks or months, or maybe a year or more.

The accounting departments of many of the principal railroad companies make up at the close of each week estimates of the receipts for that week and sometimes include estimates of the expenses. These are primarily for the information of the officers and directors of the companies, but are frequently sent to the newspapers. Thus appear estimates and cumulative estimates for the first, second, third and fourth weeks of each month and for the entire month. These are but estimates in gross, and as such serve as the earliest approximate indications of increase or decrease in the volume of traffic. They are widely regarded by business men as a barometer of the general business of the country. From these estimates various financial newspapers frequently compile tables showing approximately the earnings and expenses of a number of roads selected as representative.

As soon after the close of each month as practicable each railway company is obliged to send to the Interstate Commerce Commission a report of its total operating revenues during that month with separate specification of the receipts from freight, passengers, mail and express; of its total operating expenses with separate specification of those incurred for maintenance of way and structures, maintenance of track and equipment, for securing traffic, conducting transportation and in general; of the net operating revenue; of revenue from outside operations; of taxes; and of operating income which is the amount remaining as available for rentals, interest on bonds, appropriations for betterments, and dividends.

The filing of these monthly reports with the Interstate Commerce Commission is usually not completed until about six weeks after the close of the month to which they refer. From these official reports the Bureau of Railway Economics, an organization maintained in Washington by the railways, compiles a summary of revenues and expenses for the month which is usually issued within a week after all of the reports have been filed. Most of the newspaper publications of earnings and expenses give the amounts for the different railways separately, the information thus presented being of especial interest to the investor who wants to know what each road is doing. The compilations of the Bureau of Railway Economics, however, are of the collective earnings and expenses of the Eastern, Southern and Western groups of railways, thus showing the ebb and flow of traffic for the three great sections of the country, each of which has its peculiar economic characteristics. These publications also contain comparisons of the earnings and expenses per mile of line, thus showing the actual trend of railway business, the indication of which is often confused in other compilations by the use of aggregates applying to the total mileage, which is continually increasing to a greater or less extent. The earnings and expenses are thus also reduced to concrete and comprehensible units of measurement.

For example, in its summary of earnings and expenses for June, 1912, the Bureau of Railway Economics shows that the net revenue for the month increased about 48 cents for each day for each mile of line over the net revenue of June, 1911. It shows that during the fiscal year ending June 30, 1912, total operating revenues increased $23 per mile of line, operating expenses increased $83 per mile of line, leaving a decrease in net revenue of $60 per mile of line. An increase of $48 in taxes and a decrease in net revenue from outside operations resulted in a decrease in operating income of $112 per mile of line for the year. This is equivalent to a decrease in the operating income of the 215,000 miles of line to which these reports have applied on the average, of over $24,000,000.

The monthly report of the Interstate Commerce Commission issued usually about a month later than the summary of the Bureau of Railway Economics presents an abstract, company by company, of the monthly reports filed with it.

As soon after the close of the fiscal year as is practicable, and under penalty not later than September 30th, each railway company is required to make to the Interstate Commerce Commission an elaborate report of its transactions for the year. This includes a statement in great detail of receipts and expenditures, of mileage, of locomotives and cars, of the number of employees and their compensation, of the capitalization and capital issues, of statistics as to train miles, car miles, freight traffic movement, ton miles, passenger miles, taxes, and of profit and loss.

The statistics contained in these reports are of such great volume that their compilation requires several months, the annual report of statistics of the railways of the United States issued by the Interstate Commerce Commission not appearing as a rule until a year or more after the close of the year to which the statistics refer. It is a most valuable compendium placing before the student of railway transportation the most complete available information. The system of accounts prescribed for the railways by the Interstate Commerce Commission and the publicity in regard to their affairs which it has enforced have placed the railways in that position where far more is made public about their accounts and their affairs than is known in regard to any other industry of the United States, or any of the state or municipal governments.

In addition to all the reports that have been enumerated each railway company makes an annual report to its stockholders to which many newspapers give more or less extended reference, and many if not all of the State Railroad Commissions require separate reports.

◆

MINING IN NEW BRUNSWICK

The North Shore Railway and Navigation Company, which has sixty men working a small coal mine at Beersville, in Kent County, twenty miles from Moncton, and selling the coal to the Intercolonial Railway, has also ordered machinery for the manufacture of bricks. Dr. H. J. Von Hagan, the president of the company, declares that New Brunswick has the best material for manufacturing bricks and other clay products that can be found in Canada, or in the eastern states outside of New Jersey. He is bringing several engineers from New York to inspect the company's property in Kent County.

It is announced that a large number of miners will be brought from the Old Country to work in the mines in Queen's County, where there will be great development as soon as the Gibson and Minto Railway is completed this fall. Homes are being built for miners. The Canadian Pacific Railway will take one hundred thousand tons a year out of the district, and the Intercolonial Railway has contracted for twenty thousand tons. It is estimated that there is anywhere from one hundred million to one hundred and fifty million tons of coal in this district.

SOME OBSERVATIONS ON THE DISINTEGRATION OF CINDER CONCRETE.*

By George Borrowman.

Cinders, as an aggregate in concrete, are used rather commonly where a light, cheap mixture is desirable; also in fireproof construction, and perhaps in the latter capacity this kind of concrete finds its most important application.

Its efficiency, however, has been the subject of considerable discussion. Various tests have been made, the results of which tend to show the superiority of this material over all other fire-resisting substances. There are also several patented floors involving cinder concrete which have been used successfully. Nevertheless, it has failed in some instances when employed for ordinary purposes, cracking and disintegration taking place. These discordant results are due, no doubt, as Freitag suggests in his "Fireproofing of Steel Buildings," to the use of cinders of varying quality, but to the writer's knowledge the matter has not been further investigated. A particular case of disintegration, accompanied by a powdery efflorescence on the surface of the concrete, was observed by D. S. Avery, now Chancellor, but formerly head of the department of chemistry in this University, who prompted some study of the phenomena, and also made various helpful suggestions during the experiments.

Blocks of concrete containing cement, sand and ¼-in. cinders were first prepared, the proportions by weight being 1:2:3, respectively. The cinders were from steam coal and slack, and were carefully screened. The cement and sand were of good quality, the latter being sieved through 20-mesh on to 30-mesh screens.

Another lot was made up using cinders from ½ in. to 1 in. in size, the proportions being 1:1:1. In each case just enough water was used to insure thorough incorporation without running. All the blocks were placed on a glass plate to prevent loss of moisture and covered with a damp cloth for two weeks.

At the end of this period, the specimens having the proportions 1:2:3 showed no change, but were somewhat porous and friable, owing to the realtively large bulk of cinders. A little later, however, fine cracks developed, with general disintegration. The others (1:1:1:), though compact and hard, also showed signs of cracking, and in a short time the breaks became very pronounced. In each case they radiated from certain points.

These latter specimens were broken open to facilitate examination, and in some cases the breaks originated from cinders that showed oxidation of much iron. The surfaces of the concrete bounding the cracks crumbled easily, indi[illegible].

The appearance of these oxidized cinders suggested the presence, originally, of much ferrous iron, probably as sulphide. The analysis of the cinder stock showed considerable sulphur as sulphide and sulphate, also iron, though the proportion of ferrous iron could not be determined in material of this sort with accuracy.

Analysis of Cinders.

	Per cent
SiO_2	[illegible]
Total Iron Fe_2O_3	[illegible]
Al_2O_3	[illegible]
CaO	[illegible]
MgO	[illegible]
S	0.60
SO_3	5.82
Undetermined (C, etc.)	5.37
	100.00

It seemed probable, then, from the foregoing data, that oxidation of iron and sulphur produced internal stress and consequent cracking, aided, no doubt, by the general weakness produced by the diffusion of soluble sulphates. This theory was further strengthened by finding that the efflorescence, found on the surface of the disintegrating concrete before mentioned, was ferrous sulphate.

On this assumption attempts were made to bring about similar results by substituting for cinders artificial iron sulphide, prepared in several ways. These experiments, however, were not successful. On breaking open the blocks, the sulphide was found to be unchanged, surrounded by hard, compact cement. Soluble sulphates being absent in the mixture, the blocks had, of course, greater initial strength than those containing cinders, and would have withstood considerable stress had there been any. The lack of oxidation, though, in these tests, indicated that in the case of the cinders the necessary oxygen must have come from the cinders themselves, since they were equally well protected from the air.

This conclusion drew attention to the fact that about one-third of the cinder stock consisted of a very porous coke. As is well known, this substance will persistently occlude large amounts of oxygen. According to Starr and Lewis, air-dried coke contains absorbed gases in the proportion of about 0.7 c.c. per gram of coke, 2 to 6 per cent. of the gases being oxygen. The oxidation in the concrete was most pronounced in the coke. Moreover, some pieces of the latter were picked from the cinder stock and tested for sulphide sulphur, about 1 per cent. being found. One nodule from which cracks radiate proved to be a piece of coke so thoroughly oxidized as to look like a mass of ferric oxide. This was tested and found to contain but a trace of sulphur.

As a final experiment, some of the original stock of cinders were kept exposed to air and moisture until, on washing, they showed the presence of no soluble sulphate. They were then made into a block of concrete similar to those prepared before (1:1:1). Under parallel conditions no disturbance took place, the material retaining perfect stability.

From these tests we may conclude that cinders with much sulphide and sulphate sulphur are likely to give unsatisfactory results, especially if there is much coke or porous material present; also that such material may be improved if allowed to weather, with occasional washing, until the ferrous iron and sulphur have been oxidized and leached out.

[*] Abstract of paper in "The Journal of Industrial and Engineering Chemistry," June, 1912.

◆

HARBOR IMPROVEMENTS BEING MADE.

There are now five dredges at work in St. John Harbor. Some of them are doing work in connection with the big Courtenay Bay contract for which the Norton Griffiths Company will organize a subsidiary company, and for which new dredges are being constructed. It is expected that dredging in Courtenay Bay will be begun this fall. The other dredges are clearing the site for additional steamship berths at West St. John. With regard to the dry dock at Courtenay Bay, the present plans only provide for one [illegible] long, and an agitation is now in progress to have it made 1,150 feet, which is the length of the proposed dock at Levis.

BOOK REVIEWS.

Raising the Wreck of the U.S. Battleship, "Maine." Published by Lackawanna Steel Company, Buffalo, N.Y. Size, 8 x 10¾ inches; paper; 40 pages; price, $1.

A good deal has been written concerning the raising of the wreck of the battleship "Maine" in Havana harbor. The problem was one of the greatest engineering interest. A complete description of the entire operation has recently been issued by the Lackawanna Steel Company as Bulletin No. 102. This description is handsomely illustrated and describes in considerable detail the history of the sinking of the "Maine" and progress of the work towards its final removal. The company which publishes the book is interested because it furnished the steel piles which were used to construct the large cofferdam surrounding the wreck. This very interesting and correct description will be of considerable value in illustrating what may be done under similar circumstances.

Materials and Construction. By James A. Pratt. Published by P. Blackiston's Son & Company, 1012 Walnut Street, Philadelphia, Pa. Size, 5 x 7 inches; cloth; 187 pages; 85 illustrations; price, 90 cents.

This is a text book of elementary structural design. The author states that his purpose in compiling the text and set of problems was to present such studies in the elementary laws of construction as will give the student an understanding of the more simple formula and ability to apply such to every-day practice. The work is so arranged that it is available also as a handbook of the necessary formulae and principles of constructive details. No attempt is made to cover any advanced engineering work; only such material being included as is essential for the training of the young mechanic.

Preliminary Studies in Bridge Design. By Reginald Ryves. Published by the St. Bride's Press, Limited, London. Size, 5 x 7½ inches; cloth; with a number of illustrations; price, 60 cents.

This book is a reprint of a series of articles under the same title which appeared in "The Surveyor and Municipal and County Engineer" early in 1912, and is the first of a series of small volumes, each complete in itself, dealing with the design of ordinary highway bridges of moderate spans. The book is intended to provide the student with a foundation for the study of bridge design, and at the same time suggest to the experienced engineer that some of the facts which he takes into account in designing bridges will have more significance and greater value if he will study them in the light of the basic principles which really hold some of them together and separate these from others. This little volume will well repay reading, both to the student and the experienced engineer.

Ontario Railway and Municipal Board. The sixth annual report to December 31st, 1911. Copies may be secured from the secretary, Ontario Railway and Municipal Board, Toronto, Ontario.

Timiskaming and Northern Ontario Railway Commission. Tenth annual report for year ending October 31st, 1911. Copies may be secured through the Department of Public Works, Parliament Buildings, Toronto.

Proposed Rules and Regulations for Inside Work. Advance copies of the rules and regulations for electrical wiring compiled by the Hydro-Electric Power Commission of Ontario, to be revised and published after October 15th. Copies may be secured from the secretary, Hydro-Electric Power Commission of Ontario, Toronto.

Southern Vancouver Island. By Charles H. Clapp. Being memoir No. 13 of the Geological Survey Branch, Department of Mines, Canada. R. W. Brock, Director, Geological Survey, Department of Mines, Ottawa.

The Geology and Ore Deposits of Phœnix Boundary District, B.C. By O. E. LeRoy, being Memoir No. 21, Geological Survey Branch, Department of Mines, Canada. R. W. Brock, Director of Geological Survey, Department of Mines, Ottawa.

U.S. Department of Agriculture Publications

Bulletin No. 44, Office of Public Roads. The Physical Testing of Rocks for Road Building. By Albert T. Goldebeck and Frank H. Jackson.

Bulletin No. 46, Office of Public Roads. Oil-Mixed Portland Cement Concrete. By Logan Waller Page, Director, Office of Public Roads.

Bulletin 249, Part I., Office of Experimenting Station. Earth-Filled Dams and Hydraulic-Filled Dams. By Samuel Fortier and F. L. Bixby.

Bulletin 249, Part II., Office of Experimenting Station. Timber Dams and Rock-Filled Dams. By Samuel Fortier and F. L. Bixby. A. C. True, Director, Office of Experiment Station.

Bulletin 88, Forest Service. The Properties and Uses of Douglas Fir. By McGarvey Cline and J. B. Knapp. Henry S. Graves, Forester.

On the Measurement and Division of Water. By L. G. Carpenter. Being Bulletin 150, of the Agricultural Experiment Station, Colorado Agricultural College, Fort Collins, Colorado.

Preliminary Information Respecting Waterpowers. Being instructions relating to the gathering of certain preliminary information, prepared by Arthur V. White, M.E. Copies may be secured from the secretary of the Commission of Conservation, Ottawa, or the Department of Lands, Victoria, B.C.

Canadian Highway. Written after the planting of the first sign post of the Transcontinental Highway, by P. W. Luce, secretary, The Canadian Highway Association, Room 4, Cunningham Block, New Westminster, B.C.

Third Semi-Annual Report of the Sewage Disposal Commission. City of Fitchburg, Mass., for the six months ending March 31st, 1911.

Annual Report, Board of Water Commissioners, City of Kingston, N.Y., for the year ending February 29th, 1912, with a summary of operations for past year.

The Zinc Deposits of Northeastern Tennessee. Bulletin No. 14. By A. H. Purdue, State Geologist, State Geological Survey, State of Tennessee.

Report of the Bureau of Mines, 1912. Vol. 21, Part 2. Being reports on the District of Patricia, recently added to the Province of Ontario. Compiled and edited with an introduction by Willet G. Miller, Provincial Geologist, Bureau of Mines, Parliament Buildings, Toronto.

Calendar, The Royal Technical College, Glasgow. The Calendar of the Royal Technical College, of Glasgow, has come to hand.

◆

CATALOGUES RECEIVED.

Pocket Magnetic Compasses. Small pamphlet forwarded by Keuffel & Esser Co., New York, illustrating different types of their pocket magnetic compasses.

Sheet Steel Piling. The Lackawanna Steel Company, Buffalo, N.Y., forward their Bulletin No. 104, entitled "Lackawanna Protected Steel Sheet Piling."

Babbitt Metals. A little booklet entitled "Shakespeare and Babbitt Metals," illustrating different babbitt metals manufactured by the Canada Metal Company, Limited, head office and factory, Fraser Avenue, Toronto.

Concrete Building. Small booklet forwarded by the Aitken Cement House Company, Peoples Gas Building, Chicago, illustrating the Aitken system of reinforced concrete building construction.

Flexible Cable. Pamphlet illustrating whipcord, braided flexible cable for use in workshops and mines, is forwarded by W. T. Glover & Company, Limited, Trafford Park, Manchester, England.

Manila Rope. Being catalogue No. 12-8, a brief treatise for engineers on rope used for the transmission of power, together with formulae, tables and data used in mill engineering. The C. W. Hunt Co., West New Brighton, N.Y.

Hoisting Engines and Derricks. The Clyde Iron Works, of Duluth, Minn., forward handsome 9-in. by 12-in., cloth bound catalogue illustrating their complete line of hoisting machinery. The catalogue conveys an excellent idea of the capabilities of this plant. Copies may be secured by addressing the company at Duluth, Minn.

Four-Wheel Drive Tractor. A little booklet describing the four-wheel drive gas tractor manufactured by the Heer Engine Company of Portsmouth, Ohio, and represented in Canada by Mr. [illegible], The Canadian Heer Company, 808 McArthur Building, Winnipeg. The Heer Engine Co. also forward their catalogue of two-cylinder opposed gas-[illegible] engines.

Steam Pumps. In a [illegible] catalogue just issued by the [illegible] Steam Pump Company of New York City, the [illegible] of operation and the different engineering features of the [illegible] are fully illustrated. The catalogue gives [illegible] and curves showing the steam consumption and the cost of operating [illegible] under different conditions, and [illegible] types of pumps. Copies of this publication may be had by addressing the [illegible] Steam Pump Company of Battery Place, New York.

FIRST GOLD FROM PORCUPINE

The returns to the Ontario Bureau of Mines show that the output of the metalliferous mines and works of that province for the six months ended June 30th, 1912, was as follows:—

Product.	Quantity.	Value, 1912.
Gold, ounces	11,854	$ 235,198
Silver, ounces	14,258,403	7,936,600
Copper, tons	5,170	736,409
Nickel, tons	10,179	2,166,805
Iron ore, tons	12,342	33,060
Pig-iron, tons	283,926	3,942,638
Lead ore, tons	17	849
Cobalt, cobalt and nickel oxides, crude cobalt material, etc., lbs.	854,324	192,073

The figures of gold production as compared with the first six months of 1911, show an increase of $192,878. This is practically the first fruits from Porcupine, chiefly from the Dome mine. Since the six months ended the Hollinger mill began turning out gold, and as there are now several smaller producers as well, the output for the full year may be expected to reach a considerable sum.

The yield of silver from the Cobalt mines, measured in quantity, shows a reduction of 973,566 ounces from that of the first six months of last year, but the money value was $292,400 greater, owing to higher prices for silver.

Nickel and copper from the Sudbury mines touched high water mark, and if the production continues at the same rate, 1912 will show a record for both metals. This is also true of pig-iron. Iron ore, however, shows a falling off as compared with a year ago.

The by-products from the refining of the silver ores, such as cobalt and nickel oxides, had a value of nearly three times that of the corresponding period in 1911.

◆

MONTREAL TRAMWAYS COMPANY.

President Robert, of the Montreal Tramways Company, in response to a request made some time since by the city council, presented his suggestions of what was required to provide a better street railway service in the city of Montreal. He advocated that another east and west street in the down-town district—namely Vitre Street—be opened through to Windsor Street, at the Canadian Pacific Railway depot, and that the company be permitted to lay down tracks thereon. He further advocated that two additional north and south streets be given to the company for the purpose of laying car tracks, both streets being east of Bleury Street, the growth of the city in the north being rapid and the traffic being now too heavy for the existing lines. Grading and improving Guy Street, a north and south street in the west end, leading to the mountain side residential district, was also suggested and the president considered that the construction of a subway under the canal was very essential, to provide against interruptions to both the street car service and vehicular traffic. The elevation of the Grand Trunk Railway tracks was considered essential. Delays through the canal amounted to thirty-two hours in August and those due to waiting on trains to pass on the Grand Trunk Railway were sixteen hours. The Board of Control will consider the recommendations.

NEW METHOD OF TESTING WELDS.

A new method of testing welds was presented by Mr. C. Fremont, of Paris, in a paper read before the Congress of the International Association for Testing Materials. An abstract of the paper follows:

The impact test was selected to determine the strength of forged welds in order to ascertain the limits between which this strength is likely to vary. Small prismatic test pieces, measuring 8 x 10 mm. in cross-section, were employed. These pieces were left unpicked. The unit of comparison was the strength of the original metal. The welds were made in fairly large numbers in France and elsewhere by smiths, specially on account of their skill. The welds —steel on steel, iron on steel, and iron on iron—were of the scarf-jointed type, so as to obtain large contact surfaces. Each piece welded was of square section and about 35 mm. on the side. Macrographic etchings of the welds in all cases showed a line of demarcation between the two metals at the seat of the welds, the portions in contact not having interpenetrated.

The square section iron employed in these various welds had a tensile strength of from 35 to 40 kg. per square millimeter and the mild steel a tensile strength of about 40 kg. per square millimeter. The impact test on the unnicked test prisms 8 x 10 mm. in section gave about 50 kilogrameters in the case of the steels, the test pieces not exhibiting fissures in any instance, and from 26 to 32 kilogrameters for the iron, the fracture of the metal being fibrous. Prismatic test pieces similar to the foregoing were prepared from the welded pieces, but in such a way that the bending test could be applied in line with the welds to enable the strength of the latter to be determined. Under the impact test all these pieces exhibited in all cases a strength inferior to that of the natural metal. In most of the tests the test pieces fractured in consequence of the weld opening, the strength being insignificant, less than 1 kilogrameter. Among the better results the steel-steel test pieces underwent a fair amount of deformation before fracturing, the force required being from 15 to 16 kilogrameters; that is to say, only one-third of the strength of the original metal, which could be bent right over without breaking or even cracking.

The static strength obtained in the testing forged scarf jointed welds is equal to the static strength of the metal only when the welded surface is sufficiently large to compensate for the lower elementary strength per unit surface, just as in a brazed joint.

Autogenous welds are still weaker than forged welds, not only because of the smaller surfaces of adhesion they present, but also on account of the lack of continuity in the added metal and of not being hammered.

◆

SUBSTITUTE FOR BRIDGES IN SASKATCHEWAN.

Owing to the great width of the North and South Saskatchewan Rivers, the cost of bridging them is very high, and in order to provide the settlers with access to their markets the Government maintains an ever increasing number of ferries accross these streams.

In 1905, at the inauguration of the province, there were twenty-two government ferries. There are now thirty-three, and by the end of this season there will be five more, all of them being under construction, and some of them almost finished at the present time. Three of these new ferries will be on the South Saskatchewan, namely, north of Pennant, north of Cabri, and south of Owensville postoffice in range 21, west of the third meridian. Two will be on the North Saskatchewan, one west of Hepburn, and the other south of Frenchman's Butte.

SYNTHETIC AMMONIA PROCESS.

An announcement of special interest in New York by Professor Hofrat Bernthsen, an eminent German scientist, lecturing in the Eighth International Chemical Congress. He explained that a system has been discovered in Germany for the synthetic manufacture of ammonia, by the uniting of nitrogen and hydrogen. The ammonia is prepared by passing the gases through a tube containing a substance for promoting reaction at a temperature of about 900 degrees Fahrenheit, and under a pressure.

As ammonia is extensively used in the manufacture of ice and in the preparation of fertilizers, notably ammonium sulphate, Dr. Bernthsen predicted that its synthetic preparation was an important step forward, inasmuch as its components—nitrogen and hydrogen—may be obtained from water and air respectively, at a negligible cost. The world's consumption of ammonia for 1911 was estimated in value at $80,000,000.

◆

MINERAL PRODUCTION IN BRITISH COLUMBIA

Copper is the only mineral showing an increased production in British Columbia. Lead and zinc show decreases, while iron is a negative quantity in the preliminary review for 1911, compiled by the provincial mineralogist, Mr. W. Flett Robertson.

A considerable falling off in the production of lead is shown, the average price of which for 1911 was practically the same as for 1910. The most serious decrease was in the output of the St. Eugene mine; this amounted to more than 8,000,000 pounds. The Sullivan increased its output between 2,000,000 and 3,000,000 pounds, and to that extent reduced the decrease in quantity from East Kootenay mines as compared with 1910. Approximate figures of production for 1911 are: St. Eugene, 6,000,000 pounds; Sullivan, 11,000,000 pounds. Ainsworth Division mines produced but little lead in 1911, whereas in 1910 they contributed about 2,500,000 pounds to the total for that year, the three shippers having then been the Bluebell, Highland, and Whitewater group. The 1911 total from all properties in Ainsworth Division is estimated at less than 300,000 pounds. Slocan maintained its output, the total from the Richmond-Eureka, Ruth-Hope, and Rambler-Cariboo, and that from the Slocan Lake section—Van Roi, Standard, and Hewitt-Lorna Doone —having together been somewhat higher than the corresponding figures for 1910. Nelson Division had the Emerald and Molly Gibson mines as its chief producers of lead. There was a relatively small production from the Lardeau District, and still smaller from Portland Canal.

A statement published last autumn showed the total expenditure by the Dominion of bounty on lead to July 1st, 1911—that is, for eight years—to have been $1,617,020. Of this sum, $249,370 was paid in the fiscal year ended March 31st, 1911, and $49,714 for three months to July 1st, 1911. After deduction of $50,000 appropriated for zinc-ore reduction experiments, there remained, as at July 1st, 1911, of the $2,500,000 originally voted an unexpended balance of $832,980.

The estimated increase in the copper production of the Province, as compared with 1910, is about 1,200,000 pounds.

The Boundary District made a decreased production in 1911 by about 6,500,000 pounds (the reason for which has been already explained), and West Kootenay (chiefly Nelson Division) also shows a decrease of about 300,000 pounds; but against these decreases is to be placed an increase of about 8,000,000 pounds in the Coast District. The more important copper-producing districts of the Province are the Boundary, Coast, and Rossland; of these, the Coast bids fair to in future make a much larger output of this metal than it has done in recent years, for in both the Britannia mine, in New Westminster Division, and the Hidden Creek mine, near Goose Bay, Observatory Inlet, very large bodies of copper ore of commercial grade have been opened. No production of copper has yet been made at the latter mine, which was not extensively developed until the year just past, but it is planned to put in reduction works as soon as all arrangements necessary for smelting ore on a large scale are made. The increase in output of copper at the Britannia mine in 1911 as compared with 1910 is believed to have been between 6,000,000 and 7,000,000 pounds, but the actual output is not yet available. The Marble Bay mine, Texada Island, also made a substantial increase, but this was in part offset by a decrease at the neighboring Cornell mine. There is little comment to be made relative to either Boundary or Rossland mines in regard to their copper production, which is being generally well maintained, except when the supply of coke for the blast furnaces of the copper smelteries is interrupted.

The New York average price of electrolytic copper for 1911 was a trifle lower than that for 191—12.376 cents as compared with 12.738 cents—but the former year closed with an average for the month of December of 13.552 cents per pound, which was the highest monthly average since January, 1910. The expectation is that a higher price will rule in 1912, so the outlook for this year is considerably brighter. If this increase of one cent a pound occurred in the beginning of the year and had been maintained throughout, it would have meant an increase in the total value of this year's copper production of about $400,000, and the copper mining companies would have benefited to this increased extent.

The smaller output of zinc in 1911 than in 1910 is accounted for by the fact that it was not practicable for either the Whitewater group of mines or the Lucky Jim, in the Slocan, to ship ore, owing to the absence of transportation facilities, for the Kaslo and Slocan Railway line, six miles of which was destroyed by fire in the summer of 1910, has not yet been reconstructed. Further, the Whitewater mill, also burned, has not been replaced, though in both mines much development work has been done, and shipment of ore will take place whenever it is possible to send it out.

No zinc concentrate was produced by the Slocan Star mill, though production may be resumed in 1912. There are now three mills in Four-Mile camp, Slocan Lake, equipped for producing a zinc as well as a lead concentrate, namely, those of the Van Roi, Silverton Mines, Limited (Hewitt-Lorna Doone), and Standard. Of these, the Van Roi produced in 1911 concentrate containing more than 2,000,000 pounds of zinc, and the Silverton Mines, Limited, a much smaller quantity. The Standard mill is a new one, the operation of which was only commenced late in the year.

Some prospecting for iron ore has been going on in [illegible]

CORROSION OF IRON AND STEEL PIPE.

The resistance to corrosion of iron and steel pipe has been the subject of controversy for a long time, both steel and iron having adherents who believe the one would corrode less than the other under the same conditions. A recent series of experiments undertaken by William H. Walker, of the Massachusetts Institute of Technology, results of which were published in July, 1912, by the National Tube Co., indicates that there is no difference in the corrosion of iron and steel pipe taken on the average.

Naturally a poor steel will show less resistance to corrosion than a good iron, but the converse is also true. Comparisons should be made on practically equal grades of product.

Water which contains oxygen induces a rapid corrosion of pipe of either kind, while water without oxygen, other conditions being equal, will show much less corrosion, or none at all if no other corrosive elements are present.

Doctor Walker made 64 comparisons of steel and iron pipe where the history of the installation was known. The cases where iron was found more corroded than steel amounted to 20, and where steel was more corroded than iron to 18. There were 9 cases where there was no difference between the two.

In order to determine the relation between the so-called acid-corrosion test and actual corrosion in service an experiment was made in which pipes were subjected to 20 per cent. sulphuric acid for four hours at room temperature. Although every care was taken to have identical conditions with all samples subjected to the test, it was found that no reliance could be placed in it. It was shown to be erroneous and misleading. The acid test not only did not agree with the service test, but the steel and iron showed no agreement when considered by themselves.

ENGINEERING WORK IN QUEBEC.

Some important engineering work is in progress and projected at Quebec owing to the prospective entry of the Transcontinental Railway, which will have its eastern terminus in that city. This work includes a new bascule bridge to provide railway connections with the Louise Embankment, a pontoon to provide a berth for coasting vessels, several landing sheds, new piers to form part of other harbor work which will cost $2,000,000, and two grain elevators. Plans have been prepared, and the work is to be undertaken as soon as financial conditions permit. It is anticipated that when these proposals have been put into execution Quebec will be able to obtain a larger share of the St. Lawrence grain traffic.

* * *

The Canadian Mining Institute held their annual session in Victoria, B.C., during the week of September 15th. Some of the speakers and entertainers illustrated their topics with lantern slides, among these were, Mr. E. Jacobs, secretary of the western branch of the Institute, who spoke on the Copper Mining and Smelting Industries of British Columbia.

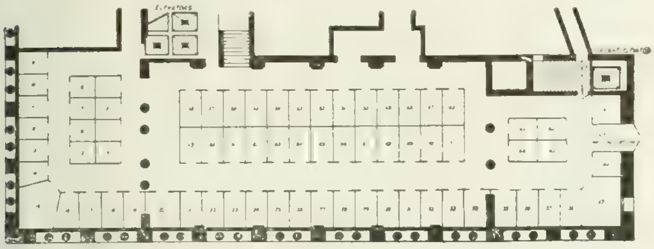
OBITUARY.

Mr. William F. [illegible], Toronto, the oldest Dominion Land Surveyor, is dead. He came to Toronto about twelve years ago from Durham, Ont., where he had lived for a great many years. In early life he was probably the best known surveyor in the employ of the government. Two of his greatest tasks were the surveying of the Counties of Grey and Bruce about half a century ago. He retired from active work [illegible]. He was [illegible] years of age.

CONVENTION OF ASSOCIATION OF RAILWAY ELECTRICAL ENGINEERS.

The fifth annual convention of the Association of Railway Electrical Engineers will be held in the Auditorium Hotel, Chicago, October 21-25.

The electrical men of all the big railroads of United States and Canada will here be gathered together for a conference on standardization of electrical practice on steam railroads, and many valuable papers and committee reports are planned.



The great hall occupying the 9th floor of the Auditorium Hotel has been reserved for convention exhibits, and judging from previous years, this space will all be taken by prominent manufacturers of electrical equipment.

Size of Booth and Cost.

Booths Nos.	Area.	Price.
1–8	42 sq. ft.	$18.90
9–14	48 " "	21.60
15	126 " "	56.70
16–18	60 " "	27.00
19	56 " "	25.20
20	90 " "	40.50
21–38	60 " "	27.00
39	142 " "	63.90
40	56 " "	25.20
41	64 " "	28.80
42–45	48 " "	21.60
46–71	60 " "	27.00

As in previous years, an excellent entertainment programme will be provided which will include an informal dance, automobile tour of Chicago's parks, theatre party, closing with the annual banquet.

◆

THE MEMPHIS UNION STOCK YARDS.

The Memphis Union Stock Yards, recently completed at Memphis, Tenn., are generally considered to be the most modern and up-to-date stock yards in the world.

About 20,000 horses and mules were sold annually in the city of Memphis before the erection of these stock yards, nearly all of them at retail. With the completion of the new structure and the wholesale trade which it is estimated that this will bring, the annual sales will undoubtedly run 60,000 to 80,000 head.

The stock yards comprise the auction and commission stables, which have a capacity of 2,000 horses and mules, a private mule barn with a capacity of over 8,000 head, and an auction pavilion arranged for the selling of from 500 to 1,000 horses and mares throughout the week.

One of the important features which had to be arranged for in the construction of these stock yards was the covering of some 400,000 square feet of the buildings with a durable fireproof roofing.

As the buildings were situated alongside a railroad, the fire risk was believed to be too great for shingles or any other inflammable roofing, and, on account of the space to be covered, a roofing unduly high in cost or that necessitated painting or gravelling, or any considerable amount of repairs or renewals, was considered impracticable. After investigation of roofings that were claimed to meet these requirements, the J-M Asbestos Roofing, made by the H. W. Johns-Manville Company, New York, was selected; in consequence, all the buildings were covered with this roofing.

This fabric is made of pure, long-fibred asbestos (stone) felt, securely cemented together with a combination of Trinidad Lake and other natural asphalts. Approximately 400,000 square feet were necessary, or about ten acres.

It is estimated that these new stock yards will effect an enormous saving between buyers and jobbers in the horse and mule business. The stock will be shipped direct to the yard by the raisers, instead of being sent to some other wholesale market and re-sold to come to Memphis. This will cut out an average additional expense of about $200 per car load by approximately $10 per head, and, with the sixty to eighty thousand head it is expected will be handled in a year, the saving approximates three-quarters of a million dollars annually.

◆

A NEW ENGINEERING FIRM.

A new office has been started by four Montreal men, a mechanical, an electrical, and two civil engineers, each with a number of years' practical experience in their several particular lines. The scope of the work to be taken up embraces all kinds of estimating for contractors and their engineers, such as taking out quantities on building work to assist the contractor in tendering on contracts, estimating on heating, plumbing, ventilating and electric lighting, making up valuations for insurance purposes, drawing up detail plans for every description of engineering work. There should certainly be a field for such an engineering firm in this country. The address and offices of the company are: Estimators and Quantity Experts, 210 Board of Trade Building, Phone Main 786, Montreal.

◆

PERSONAL.

MR. JAMES T. CHILD, city engineer of Calgary, Alta., has tendered his resignation to the city commissioners.

MR. FRED L. OLMSTEAD, of Boston, Mass., has been engaged by the Toronto Harbor Commission in connection with the preparation of plans for the water front of this city. Mr. Olmstead is well known amongst municipal officials both in Europe and North America.

MR. FRANK L. CODY has resigned as assistant manager for the Northern Ontario Light & Power Company, at Cobalt, Ont., because of ill health. Mr. Cody has been in Cobalt district for the last six years, and was formerly general manager of the Great Northern Silver Mines and the Cobalt Light, Power and Water Company.

DR. A. E. BARLOW, president of the Canadian Mining Institute, left Montreal for British Columbia, August 18th. His intention is to visit a number of the mining centres in West Kootenay and elsewhere before proceeding to the Coast. He presided at the western meeting of the institute in Victoria on September 18th and 19th, and will preside also at a meeting to be held September 30th, at Frank, Alberta.

MR. A. D. WOODMAN, of the Canadian Domestic Engineering Company, Limited, Toronto and Montreal, has been elected to membership in the Engineers' Club, of Toronto. Mr. Woodman's firm has obtained a large number of Toronto contracts within the past couple of years, including the new Technical School, on which the engineering work will probably amount to $350,000. At the present time the Canadian Domestic Engineering Company, Limited, has approximately ninety contracts on hand for engineering work in connection with heating, ventilating and power houses.

◆

COMING MEETINGS.

AMERICAN ROAD CONGRESS.—First Annual Session to be held in Atlantic City, N.J., at the Million Dollar Pier, September 30th to October 5th, 1912. Secretary, J. E. Pennybacker, Colorado Bldg., Washington, D.C.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE CANADIAN HIGHWAY ASSOCIATION.—Meeting will be held in Winnipeg, Man., October 9th to 12th. Secretary, P. W. Luce, Room 4, Cunningham Block, New Westminster, B.C.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Power, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

◆

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE: Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W. Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 409 Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible]

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-jack. Meets every first and third Friday of each month, October to April, in [illegible]

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION—President, Mayor Lees, Hamilton; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES—[illegible] Sec.-Treasurer E. Hingley, [illegible]

[illegible]

THE UNION OF CANADIAN MUNICIPALITIES.—President, [illegible]; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., [illegible]

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, [illegible]; Hon. Secretary-Treasurer, J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. [illegible]; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor [illegible]; Secretary, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor [illegible]; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, [illegible]; Secretary-Treasurer, [illegible], Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, [illegible], Man.; Secy.-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto. Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2129 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

TENDERS.

Brockville, Ont.—Tenders for the construction of a timber superstructure of wharf, on part of the Tunnel Bay Dock at Brockville, Ont., will be received by R. C. Desrochers, secretary, Department of Public Works, Ottawa, until October 2, 1912. Plans, etc., at the offices of the Department of Public Works, Ottawa; S. J. Chapleau, Esq., district engineer, Corry Building, Ottawa, Ont.; J. G. Sing, Esq., district engineer, Confederation Life Building, Toronto; and on application to the postmaster at Brockville, Ont. (See advt. in Canadian Engineer.)

Cobourg Harbor, Ont.—Tenders for the construction of an extension to west breakwater at the entrance to Cobourg harbor, Northumberland County, Ont., will be received at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa, until October 16th, 1912. Plans, etc., at the office of this Department, and at the offices of J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont.; J. L. Michaud, Esq., District Engineer, Merchants Bank Building, Montreal, P.Q.; and on application to the postmaster at Cobourg, Ont.

Dalhousie, N.B.—Tenders for dredging required at Dalhousie, N.B., will be received until September 30, 1912, at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa. Full particulars may be obtained at this office.

Dorchester, Ont.—Tenders for the construction of a drain in the Township of North Dorchester will be received until September 30. Plans and specifications may be seen at the office of C. A. Jones, Petrolea, and the clerk's office, Dorchester. R. Bankes, reeve; W. B. Lane, clerk.

Fort William, Ont.—Tenders for dredging required at Fort William will be received by R. C. Desrochers, secretary, Department of Public Works, Ottawa, until October 1st, 1912. Full particulars may be obtained on application to the secretary.

Fort William, Ont.—Tenders for building Blake School No. 1 will be received up to September 30th, 1912. Specifications may be seen at W. C. Hulbert's, secretary-treasurer, Blake, Ont.

Glen Williams, Ont.—Tenders will be received for concrete dam at Glen Williams, Ont. Plans and specifications can be seen at Muldron & Rudd, engineers, Guelph, or at Glen Woolen Mills, Glen Williams.

Kenora, Ont.—Tenders received until 28th of September, 1912, by H. F. McNaughten, secretary, Department of Public Works, Toronto, Ont., for heating, plumbing, electric wiring, slate roofing, galvanized iron work, plastering, painting and glazing required for the registery office in course of erection at Kenora. Plans and specifications can be seen at above department, and at the Court House in Kenora.

Kingston, Ont.—It is expected that the Dominion Government will shortly call for tenders for the erection of a steel bridge across Kingston harbor. Plans for a temporary bridge to replace the old structure while a causeway is being built are in the hands of Chief Engineer Chapleau.

Ottawa, Ont.—Tenders addressed to C. W. Macnab, county clerk, will be received until 9th October, 1912, for the construction of a bridge on the town line between the counties of Lanark and Carleton. Bids are asked for a bridge having concrete abutments and concrete floor upon steel beams; likewise, upon alternate plans for a wooden bridge. Clear span, 25 feet. Plans and specifications may be seen and forms of tender obtained at the office of R. W. and S. E. Farley, 164 Sparks Street, Ottawa.

Toronto, Ont.—Mr. B. Ripley, engineer grade separation, Canadian Pacific Railway, will receive tenders up to noon October 5th, for the construction of a sub-structure on the Avenue Road Subway. (See advt. in this issue Canadian Engineer.)

Toronto, Ont.—Tenders for the equipment of windows, fanlights, etc., in the City Hall, with metal weather strip, will be received until October 8, 1912, by G. R. Geary (Mayor), chairman Board of Control, City Hall, Toronto. Full particulars, etc., at the offices of the Property Department, City Hall, Toronto.

Toronto, Ont.—[illegible] trades mentioned in connection with a shelter in Ketchum Park, Toronto, will be received by G. R. Geary (Mayor), chairman Board of Control, City Hall, Toronto, up to noon of October 8th, 1912: Mason work, etc., carpenter work, galvanized iron, plumbing, heating, electric wiring and fixtures, plastering, painting and glazing. Plans and specifications at the office of the City Architect, City Hall, Toronto.

Vancouver, B.C.—Tenders for the installation of ornamental light standards on a number of streets will be received until October 17th, 1912, by Wm. McQueen, city clerk, City Hall, Vancouver. Particulars at the office of the city electrician, City Hall.

Vancouver, B.C.—Tenders (in lump preferred) will be received by Messrs. Burke, Horwood and White, architects, 28 Toronto Street, Toronto, until October 24th, 1912, for all trades, except plumbing, heating, wiring and the general mechanical equipment, required in the erection of a departmental store at Vancouver, B.C., for the Hudson's Bay Company. Drawings, etc., may be seen at the offices of the architects after September 28th and at the offices of the Hudson's Bay Company as follows:—Winnipeg, on and after October 1st; Vancouver, on and after October 5th. Also at office of clerk of works at new building of the Hudson's Bay Company now being erected at Calgary.

Victoria, B.C.—The time for receiving tenders for schoolhouse, Powell River, is extended up to noon of September 30th, 1912. J. E. Griffith, public works engineer, Department of Public Works, Victoria.

Winnipeg, Man.—Tenders for cutting approximately 500 cords of cedar posts into paving blocks will be received until September 27th, 1912, by the chairman, Board of Control, Winnipeg. Particulars at the office of the City Engineer, 223 James Avenue, Winnipeg.

Winnipeg, Man.—Tenders for the manufacture and delivery, f.o.b., Winnipeg, of 3,200 k.w. self-cooling, oil-insulated, single-phase transformers will be received until September 25th, 1912. Particulars at the office of the City Light and Power Department, 54 King Street. M. Peterson, secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders will be received until September 30th, 1912, at the office of M. Peterson, secretary, Board of Control Office, Winnipeg, for the supply and installation of two additional boilers in the Hospital Power House and for the construction of a concrete tunnel and necessary pipe and connections from the boilers to the King George Isolation Hospital. Full particulars at the office of the City Engineer, 223 James Avenue.

Winnipeg, Man.—The time for delivery of competitive drawings for plans of proposed new city hall for the city of Winnipeg has been extended up to noon of February 15th, 1913. Further information may be obtained on application to M. Peterson, secretary, Board of Control Office, Winnipeg.

◆

CONTRACTS AWARDED.

Calgary, Alta.—A rough estimate prepared from tenders received indicate that the cost of erecting the high-level [illegible] include pavements, car rails or electric light. The materials of construction are reinforced concrete.

Edmonton, Alta.—Messrs. John Coates and Company, Limited, of London, England, have been awarded a contract by the municipal council for the supply and erection of a [illegible] The following were the tenders received and considered: Gorman, [illegible]

Edmonton, Alta.—On the recommendation of R. H. Par- [illegible]

Galt, Ont.—[illegible]

[illegible]

[illegible]

Amount involved is $[illegible]. Building of reinforced concrete finished with glazed tile.

Ottawa, Ont.—The Peter Lyall Company has been awarded the contract for the new custom house at Montreal, the figure being $[illegible].

Saskatoon, Sask.—The Board of Works have awarded contract to Messrs. King and McIndoe for the laying of sewer and water mains on 14th Street from Lansdowne Avenue 433 feet eastward.

Sherbrooke, Que.—School, $28,000; owner, Catholic School Commisisoners; architect, J. W. Gregoire, Sherbrooke; general contractor, Simoneau & Din; three stories, 132 x 55 ft.; concrete foundations, brick, with stone trimmings, gravel roofing.

Vancouver, B.C.—Store and rooming-house, $32,000; owner, Mrs. H. B. Hamilton; architect, Mr. Arthur J. Bird; contractors, Messrs. Wiles & Fisher; four stories, mill construction.

Vancouver, B.C.—Office and store building, $30,000; four stories, reinforced concrete, white terra cotta for exterior. General contractor, Mr. C. L. Williams; architect, Mr. S. B. Birds; owners, Messrs. Richards, Akroyd & Co.

Vancouver, B.C.—Contract for the erection of a five-story mill construction warehouse building for Mr. Charles Milne, was awarded to Messrs. Booker, Campbell & Whipple. Cost will be about $50,000. Mr. Thomas Hooper is architect.

Victoria, B.C.—Two small contracts for public buildings have been let by the Department of Public Works. At Quesnel a two-room school and outbuildings contract given to Mr. H. C. Joyce, of that place, the amount of tender being $5,400. At Fort George a new courtroom and a cell attached, contract for the work given to the contracting firm of Bronger and Flynn, of Fort George, the price to be paid being $2,750.

Winnipeg, Man.—The municipal fire, water and light commissioners have given instructions for the sinking of fifteen more wells in order that the water supply might be augmented pending definite action on the recent report of Prof. Slichter.

◆

RAILWAYS—STEAM AND ELECTRIC.

Preston, Ont.—The management of the Preston Car and Coach Company have secured the Canadian manufacturing rights of the gasoline electric cars recently tried out on the lines of the Canadian Northern Railway.

Province of British Columbia.—The officials of the Canadian Pacific Railway will call tenders for the construction of a portion of the line to extend from McBride Junction and Courtenay. The section to be constructed is in the Comox Valley.

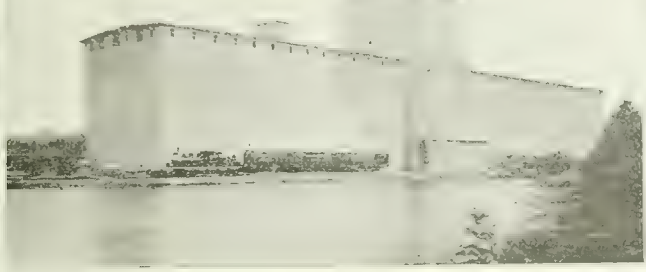
Moose Jaw, Sask.—[illegible]

Barrett Specification Roofs



On Four Great Granaries

To cover the four huge granaries illustrated herewith the Canadian Pacific R. R. engineers chose Barrett Specification Roofs for good and sufficient reasons.

These practical men know that these roofs will last *20 years or more.*

They further know that they will need no painting or maintenance expense of any kind and that the net cost per year of service will be infinitely lower than could be shown by any other type of roofing.

It is for these very reasons that Barrett Specification Roofs are used on more first-class buildings in the United States and Canada than any other kind

A big roof generally means a Barrett Specification Roof, for the reason that the cost of big roofs is carefully scrutinized and ultimate economy carefully considered. Small roof areas ought also to have Barrett Specification Roofs, because they are just as economical and satisfactory there.

Copy of The Barrett Specification with tracings ready for incorporation into building plans free on request. Address nearest office.

Special Note

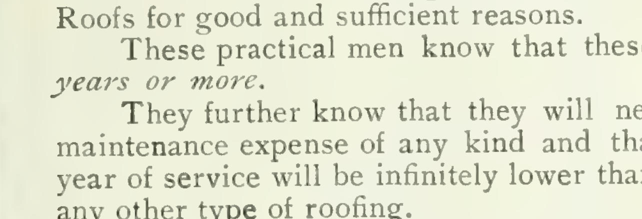
We advise incorporating into plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

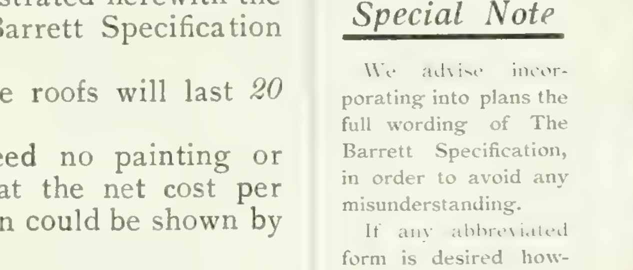
If any abbreviated form is desired however, the following is suggested:

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15th, 1911, using the materials specified, and subject to the inspection requirements.

THE PATERSON MANUFACTURING CO., Limited

MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.





BUILDINGS AND INDUSTRIAL WORKS.

Edmonton, Alta.—The municipal school board has decided to erect two temporary buildings and will call tenders in a few days for the construction of the same.

Fort William, Ont.—A newly-formed concern, taking the name of the Superior Brick Company, have selected a site and will erect a plant involving an expenditure of $250,000. Mr. A. A. Ayer is president and general manager of the new company.

Hamilton, Ont.—The Buffalo Brakebeam Company, a large Buffalo concern, which has a small branch in Brantford, has decided to establish a large branch in Hamilton. It has been awarded a large contract by the National Steel Car Company. A temporary plant will be opened on the property of the Hammant Steel Car Company.

London, Ont.—Plans have practically been completed in New York for the new $300,000 hotel which is to be erected in this city.

Medicine Hat, Alta.—Plans have been completed for the erection of a factory by the Canadian Fireproofing Company. The cost of this work is estimated at $75,000.

Moose Jaw, Sask.—The directors and officials of the Young Men's Christian Association have decided to erect a $250,000 building in this city.

Niagara Falls, Ont.—A report states that Mr. E. F. Pollard Company have purchased a site and will commence construction work on a factory to cost $15,000.

Port Arthur, Ont.—The Victoria Hotel will add two stories for accommodation to the travelling public. C. E. Tyner, proprietor.

The Superior Brick Company will erect a plant at Rosslyn, about six miles from this city, for the manufacture of pressed brick, tile, hollow block, etc. Capital paid [illegible]

Regina, Sask.—The management of the Capital Laundry Company intend to erect a building suitable for the needs of the business. Mr. Nevens is manager.

Saskatoon, Sask.—The Board of Works have approved the plans for the new city's stables. Tenders will be called for the erection of the building shortly. Estimated cost is $15,000.

St. Catharines, Ont.—Mr. Charles Taylor, of the Bishop Construction Company, Toronto, has purchased a block of [illegible] of the bungalow style.

Toronto, Ont.—A report states that the management of the Queen's Hotel may build an addition to their present [illegible]

Toronto, Ont.—According to a statement made at a re- [illegible] Postmaster General.

Tofield, Alta.—Mr. W. G. White, Industrial Commis- [illegible] machine shop will be erected here within a short time.

Vancouver, B.C.—The municipal council intend to call [illegible]

CURRENT NEWS.

Kamloops, B.C.—The ratepayers endorsed by-laws calling for expenditures as follows:—

Hydro-Electric	$250,000 00
Water	90,000 00
Electric light	65,000 00
	$405,000 00

The source of power will be the Barrier River, a distance of forty miles.

Levis, P.Q.—A statement was recently made during a banquet in this city to the effect that the site for the Quebec drydock had not as yet been selected.

Lindsay, Ont.—The ratepayers endorsed a by-law granting a loan of $12,000 to the Fitzsimmons Auto Supply Company.

London, Ont.—The municipal council have selected a site on which to erect a new city hall.

Montreal, P.Q.—There are six ten-story buildings now under construction in this city all within a short distance of each other.

Moose Jaw, Sask.—Builders in this city have offered competent carpenters the sum of 55 cents per hour in order that the pending strike may be averted.

Province of Saskatchewan.—Mr. R. O. Wynne-Roberts will prepare a report for the government of this province on the best methods of developing power from the lignite fields in this vicinity. In this connection he made a three weeks' trip through the United States.

St. Thomas, Ont.—The ratepayers recently endorsed three industrial by-laws, and by this vote Mr. Gerrard Noble will be granted a loan of $35,000 for the establishment of a biscuit company, Mr. A. J. Strough will be given assistance in the establishment of a steel grave vault, and Mr. W. G. Rogers, of the Erie Iron Works will be granted a loan of $15,000 for the extension of his plant.

Sydney, C.B., N.S.—The municipal council will consider the matter of erecting a new city hall at an early date. Mr. Kelly is mayor of this town.

Sydney, C.B., N.S.—The municipal council will consider municipality has recommended to the council that a food inspector be appointed.

Vancouver, B.C.—In the construction of the new Great Northern dock now under way at Burrard Inlet a number of piers are being used that are in many ways a novelty. They consist of frame work composed of steel rods covered with a herring-bone lath with concrete plastered over the outside to a depth of about three inches. This gives a hollow form very convenient for handling and shipping, but when placed in position on the dock site they will be filled with concrete and stones. The weight of the empty tube on a box car is about six tons.

Winnipeg, Man.—The cost of the recent water enquiry [illegible] Prof. Slichter's expenses of $100 per day.

DEPT. OF RAILWAYS AND CANALS, WELLAND

Superintending Engineer's Office,
Messrs. Wettlaufer Bros., St. Catharines, Feb. 7th, 1912.
No. 178 Spadina Ave., Toronto.

Dear Sirs: Replying to yours of the 6th, I beg to say that the two Mixers received from you last summer proved to be very handy, useful machines. They turned out excellent concrete and we had no trouble with them at all.

Yours truly, J. L. WELLER, Superintending Engineer.

CANADIAN NORTHERN RAILWAY

Belleville, Ont., Feb. 14th, 1912.
Wettlaufer Bros.,
178 Spadina Ave., Toronto, Ont.

Dear Sirs :—I think it is my duty to inform you that I am entirely satisfied with the two Concrete Mixers purchased from you last season. I have tested them in every way possible, and in every case I have found them capable of doing first-class work. Yours sincerely, J. O. GIROUX.

We have manufactured concrete mixers and concrete machinery of all kinds for many years; also previously had taken contracts for concrete work of all kinds, and have had the actual experience of just what a concrete mixer should do. Wettlaufer Mixers are perfect to-day through the help of the hundreds of contractors who purchased Wettlaufer Mixers in past years. We have gone personally to them and watched these machines working on all classes of work, asked the contractors their opinions, and so have evolved the present perfect mixer.

Compare the thoroughness, simplicity and durability of our mixer with other makes. The Wettlaufer Mixer is of the heart-shaped drum type; this means quick and positive mixing and the saving of power.

[illegible] C.N.R. to construct across and divert [illegible] and Secs. 10 and 15, Tp. 16, [illegible]

[illegible] C.N.R. to construct across thirty [illegible] highways on its Calgary-MacLeod Branch.

[illegible] Ry. to construct across the [illegible] Parish of St. Dorothee, Co. Laval, Que., mileage 39.6, east of Hawkesbury.

17421—September 6—Authorizing C.N.O. Ry. to construct across public road at station 142.70, between Tps. of Bristol and Clarendon, Co. Pontiac, [illegible] railway over highway.

[illegible] C.N.O. Ry. to construct bridge across creek at station 754.15, Tp. of Ferris, Dist. Nipissing, at mileage 223 from Ottawa.

[illegible] C.N. Branch Lines Co. to construct across fourteen (14) highways on its Canora-Sturgis Branch.

17424—September 6—Authorizing the James Bay and Eastern Ry. Co. to [illegible] Lake St. John, mileage [illegible], from Roberval.

17425—September 7—Authorizing G.T.P. Branch Lines Co. to construct its Regina-Moose Jaw Branch across 4 highways between mileage 40.01 [illegible]

17426—September 6—Authorizing C.P.R. to use and operate bridge No. 68.0 on the Muskoka Sub. Div., Ontario Division.

[illegible] C.P.R. to reconstruct bridge No. [illegible] over Blind River, Algoma Sub. Div., Lake Superior Div.

17428—September 6—Authorizing C.L.O. & W. (C.P.R.) to construct [illegible] highways from mileage [illegible] to mileage [illegible]

[illegible] Algoma Central & Hudson Bay Ry. to open for traffic its line of railway between Hawk Lake Junction and [illegible] (to connect with C.P.R.).

17430—September 6—Authorizing G.T.R. to construct branch line or spur into the premises of the Standard White Lime Company, Limited, near Beachville, Ontario.

[illegible] G.T.P. Branch Lines Company to construct across and divert highway on its Melville-Regina Branch, N.W. [illegible] Sask.

[illegible] C.N.R. to construct bridge over the [illegible] River, [illegible], Man.

[illegible] C.N.O. Ry. to construct across [illegible] Nipissing, mileage [illegible] from Ottawa.

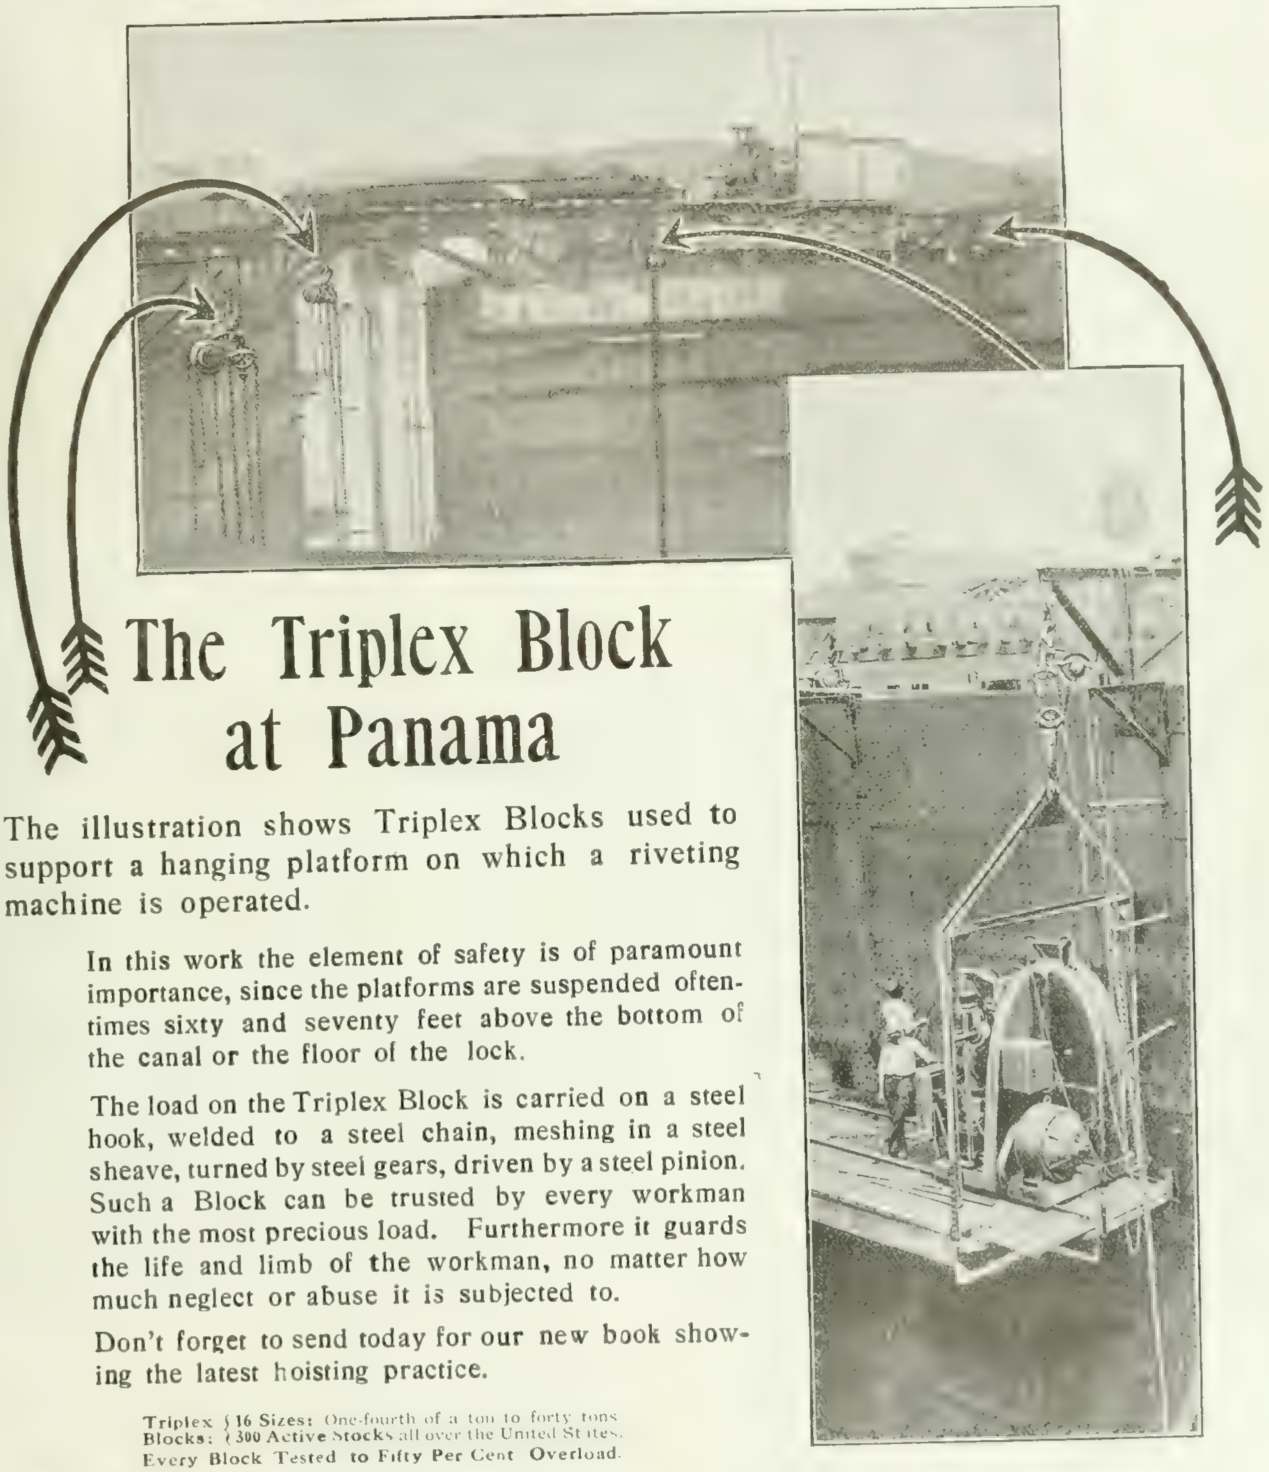
[illegible] C.P.R. to construct across two tracks [illegible] St. Johns, Que., mileage [illegible]

[illegible] C.P.R. to construct extension to the spur already constructed for W. J. Riley, at mileage 20.1 on Lac du [illegible]

17436—September 4—Extending the time within which the Walkerton & Lucknow Ry. (C.P.R.) construct spur for National Portland Cement Co., [illegible]

[illegible]

THE TRIPLEX BLOCK



The Triplex Block at Panama

The illustration shows Triplex Blocks used to support a hanging platform on which a riveting machine is operated.

In this work the element of safety is of paramount importance, since the platforms are suspended oftentimes sixty and seventy feet above the bottom of the canal or the floor of the lock.

The load on the Triplex Block is carried on a steel hook, welded to a steel chain, meshing in a steel sheave, turned by steel gears, driven by a steel pinion. Such a Block can be trusted by every workman with the most precious load. Furthermore it guards the life and limb of the workman, no matter how much neglect or abuse it is subjected to.

Don't forget to send today for our new book showing the latest hoisting practice.

Triplex { 16 Sizes: One-fourth of a ton to forty tons
Blocks: { 300 Active Stocks all over the United States.
Every Block Tested to Fifty Per Cent Overload.

[illegible] C.P.R. [illegible] ballast pit at Algoma, Coul location A, Con. 2, Tp. of Long, Dist. Algoma, [illegible]

17448—September 10—Authorizing C.P.R. to construct branch line or spur into premises of Gus Pech Foundry & Mfg. Co., Regina, Sask.

17449—September 10—Authorizing C.P.R. to construct extension to present spur for Taylor-Forbes Co., Ltd., Guelph, Ont.

17450—September 10—Authorizing G.T.R. to constrcut siding into premises of the Breakwater Co., on Lot 14, Con. 1, L. E., Tp. of Bertie, [illegible]

17451—September 7—Authorizing C.N.O. Ry. to construct across tracks of Nosbonsing & Nipissing Ry. Co., Tp. of Ferris, Dist. Nipissing, mileage 217.9 from Ottawa, with overhead bridge.

[illegible] du Fort, Que. (C.N.R.).

17453—September 12—Approving revised location C.N.O.R. Sudbury-Port Arthur line through unsurveyed territory in Dist. of Algoma, mileage [illegible] Port Arthur.

17454—September 12—Approving revised location C.N.O.R., Sudbury-Port Arthur line through unsurveyed territory, Dist. Thunder Bay, mileage 268.03 to mileage 269.3 from Port Arthur.

[illegible] truct across two highways on Lot 13, and Lots 10, 11 and 12, R. "A," Tp. Ouiatchouan, Co. Lake St. John.

17456—September 12—Approving C.L.O. & W. (C.P.R.), plan of subway on road allowance between Lots 8 and 9, Con. 4, Tp. of Scarborough.

17457—September 13—Amending Order No. 17190, in Re. C.P.R. expropriating lands for its Windsor Street Station, Montreal, Que.

17458—September 12—Approving C. N. Branch Lines Co.'s location through Tps. 19 to 24, Rgs. 1 and 2, W. P. M., mileage 36.58 to mileage [illegible]

17459—September 12—Authorizing C.N.O.R., to open for carriage of traffic its line of railway, in Tp. of Camden, Co. of Addington, mileage [illegible]

17460—September 12—Authorizing C.N.O.R. to open for traffic its line of railway, Tp. of Camden, Co. of Addington, mileage 145.83 to mileage 149 from Toronto.

17461—September 12—Approving James Bay & Eastern Ry. Co., extension from Roberval, Tp. of Dufferin, Co. Lake St. John, mileage 30.7 [illegible]

17462—September 12—Approving location Alberta Interurban Ry. Co., Ltd., from north line of Sec. 31, Tp. 24, R. 28, to east line of Tps. 27-28, [illegible]

17463—September 12—Approving location Alberta Interurban Ry. Co., Ltd., from east line, Tps. 27-28, R. 27, W. 4 M., to a point in Sec. 15, Tp. 29, R. 23, W. 4 M., from mileage 38.36 to mileage 66.80; and to construct along highways.

17464—September 13—Approving Dominion Atlantic Ry. Co., plans showing sub-structure of bridge to be constructed over the Gaspereaux River, at Horton Landing, Co. Kings, N.S.

17465—September 13—Approving revised location of Dominion Atlantic [illegible]

17466—September 10—Approving location G.T.P. Branch Lines Co. from [illegible]

[illegible]

[illegible] additional tracks across the public road south [illegible] Cadastral, No. [illegible] and change location of its station at St. Hyacinthe, Que.

17482—September 16—Authorizing C.P.R. to construct spur for L. Villeneuve & Co., Ltd., on Maude St., (not open), in city of Montreal, Que., at Mile End Station.

17483—September 14—Authorizing C.N.R. to construct across public road between Secs. 7 and 8, Tp. 31, R. 14, W. 4 M., on its Goose Lake Extension.

17484—September 17—Granting leave to Alberta Interurban Ry. Co. to cross G.T.P. Ry. [illegible] Tp. 24, R. 29, W. 4 M.

[illegible] September 17—Approving location Alberta Interurban Ry. Co. from mileage [illegible] to mileage [illegible]

17486—September 17—Approving location Alberta Interurban Ry. Co. from Fifth Meridian East to North Line of Sec. 31, Tp. 24, R. 28, W. 4 M., mileage 2.28 to mileage 9.93.

17487—September 14—Authorizing G.T.P. Ry. to construct its Calgary Boundary Branch across fifty-two (52) highways, from mileage 27.67 to mileage 111.29, Dist. South Alberta.

17488—September 16—Authorizing Michigan Central Ry. Co. to construct two passing tracks across concession road between Cons. 6 and 7, Tp. of Crowland, Co. Welland, Ont.

17489—September 16—Authorizing C.L.O. & W. (C.P.R.) to construct across four (4) highways, Tp. Sidney, Co. Hastings, Ont.

17490—September 17—Extending time until the 15th day of October, 1912, for C.N.R. to complete fencing, cattle guards, return fences and crossing signs, on its line from Grosse Isle, Man., to end of track, a distance of 31 miles.

17491—September 16—Varying Order No. 15449, dated Sept. 15th, 1911, to provide half interlocking plant instead of full interlocking plant, where Winnipeg Electric Ry. Co. crosses Selkirk Branch, C.P.R., on Selkirk Ave. and McPh[illegible] Street, Winnipeg, Man.

17492—September 16—Amending Order No. 17384, Sept. 4th, 1912, re express charges on cream, to make it apply between all points west of and including Port Arthur, within the Provinces of Ontario, Manitoba, Saskatchewan, and Alberta, instead of between all points west of Port Arthur.

17493—September 16—Suspending Supplement No. 10, to M.C.R. Co.'s Local and Joint Commodity Tariff, C.R.C., No. 1743, pending hearing. Application of Power City Stone Co., Ltd., Niagara Falls, Ont.

17494—September 16—Authorizing Commissioners of Transcontinental Ry. Co. to operate trains over crossing where it crosses C.P.R., near St. Leonards, New Brunswick.

17495—September 17—Approving Ontario & Quebec Ry. Co. plan of covered platform to be constructed at Windsor, Ont.

17496—September 17—Approving M.C.R. Co. plan of culvert to be constructed on West Town Line Road, Tp. Maidstone, over Mooney Creek Drain.

17497—September 17—Authorizing G.T.R. to construct siding with spur therefrom, for the Knechtel Furniture Co., Ltd., of Hanover, Ont.

17498—September 17—Extending, until the 30th Sept., 1912, the time [illegible] the Dominion Atlantic R[illegible] crosses highway short distance east of Berwick Station, Nova Scotia.

17499—September 17—Authorizing C.P.R. to construct spur into the premises of the Canadian Western Lumber Co., Ltd., on Lot 48, Group 1, New Westminster Dist., at Fraser Mills, B.C.

17500—September 16—Approving location C.P.R. station at Twin Butte, British Columbia.

17501—September 17—Authorizing C.P.R. to construct bridge No. 86.16, over Woman River, Chapleau Subdivision, Lake Superior Division.

17502—September 17—Authorizing C.P.R. to open for traffic that portion of its Kootenay Central Branch from Colvalli, mileage 0, to Fort [illegible]

[illegible] Approving revised location G.T.P. main line from [illegible] north line of Lot 4077 to east line of Sec. 22, Tp. 15, mileage 347.5 to mileage 372.4, east of Prince Rupert, Coast District, Range 5, B.C.

[illegible] G.T.P. [illegible] 449.18 to 452.94, east of Prince Rupert, Cariboo Dist., Range 4, B.C.

[illegible] C.P.R. [illegible] Blue, in S.W. ¼ Sec. 4, Tp. 18, R. 18, W. 2 M., at Pilot Butte, Sask.

17506—September 17—Authorizing C.P.R. to construct spur for city of [illegible] lanes, and along Lot 26, all in Block 13; across First, Second, Third and [illegible] Moose Jaw.

[illegible]

[illegible]—September 18—Authorizing C.L.O. & W. (C.P.R.) to construct [illegible]

[illegible]

The Canadian Engineer

An Engineering Weekly

NEW GRAIN ELEVATOR FOR THE HARBOR COMMISSIONERS OF MONTREAL.

The marine traffic of the port of Montreal is second only to that of the port of New York among all the ocean ports of North America. An important portion of the export traffic from Montreal is grain, which is, for the greater part, wheat from the Western provinces of Canada.

Prior to 1910 the export grain handling equipment in Montreal harbor consisted of a 1,000,000-bushel steel elevator, owned and operated by the harbor commissioners, adapted for unloading lake and canal vessels, but not designed for railway car traffic; a 1,000,000-bushel steel elevator owned and operated by the Montreal Warehousing Company (a corporation subsidiary to the Grand Trunk Railway), equipped for the unloading of both railroad cars and inland vessels; two obsolete wooden elevators, owned by the Canadian Pacific Railway, and since torn down; and a small fleet of floating transfer elevators of varying age and efficiency.

In the early part of 1910 the harbor commissioners of Montreal determined on the immediate construction of a new grain elevator of the highest class to provide (a) a rapid and efficient plant for the unloading of those railway cars for which the Grand Trunk elevator was not available; (b) extensive additional capacity for quick unloading of inland vessels, which were often being delayed for days in the harbor waiting to be unloaded; (c) sufficient additional storage capacity so that merchants could hold grain at the exporting point when it became advantageous to do so, and to eliminate the necessity for direct and almost direct transfer of inland cargoes to ocean vessels; (d) facilities for shipping grain from the new elevator, not only to the present vessel berths but to others under course of planning.

The harbor commissioners retained John S. Metcalf Company, Limited, as their constructing engineers for the new elevator. This company were the designers and builders of the Grand Trunk elevator in Montreal harbor, and of the great export grain conveyer system belonging to the commissioners, so that they were familiar with the developments of the port and the details of the problems to be solved.

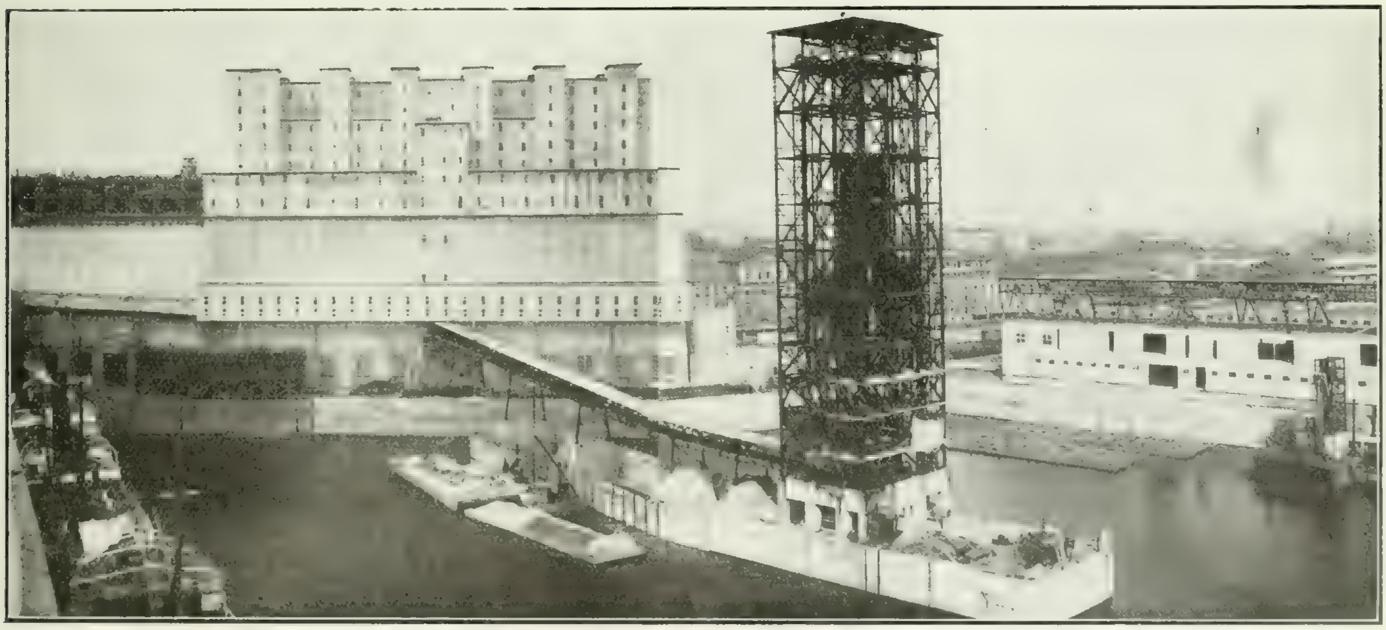

Fig. 1.—General View of Elevator from Outer End of Jacques Cartier Pier.

The instructions were to provide the best, in structure, equipment and efficiency. The commissioners were resolved that Montreal's export traffic in grain should not suffer through lack of thorough facilities.

In the summer of 1912 the elevator and a portion of the shipping conveyers were ready for the handling of car grain; and the marine unloading will be in operation October 1st.

Even though the capacity of the new elevator was to be 1,772,000 bushels, it was found in 1911 that the storage room of the port would still be inadequate; and as the elevator was to have machinery equipment suitable for taking care of several millions of bushels of storage capacity, the commissioners ordered the capacity of the elevator to be increased by 850,000 bushels, making the total capacity of the [illegible] bushels. The storage addition will be ready for grain this fall.

A description of the important features of the work follows:

Structures.

Dimensions.—The elevator, including the storage addition, is 456 feet 8 inches long by 100 feet wide, and 220 feet high to the tops of the leg towers.

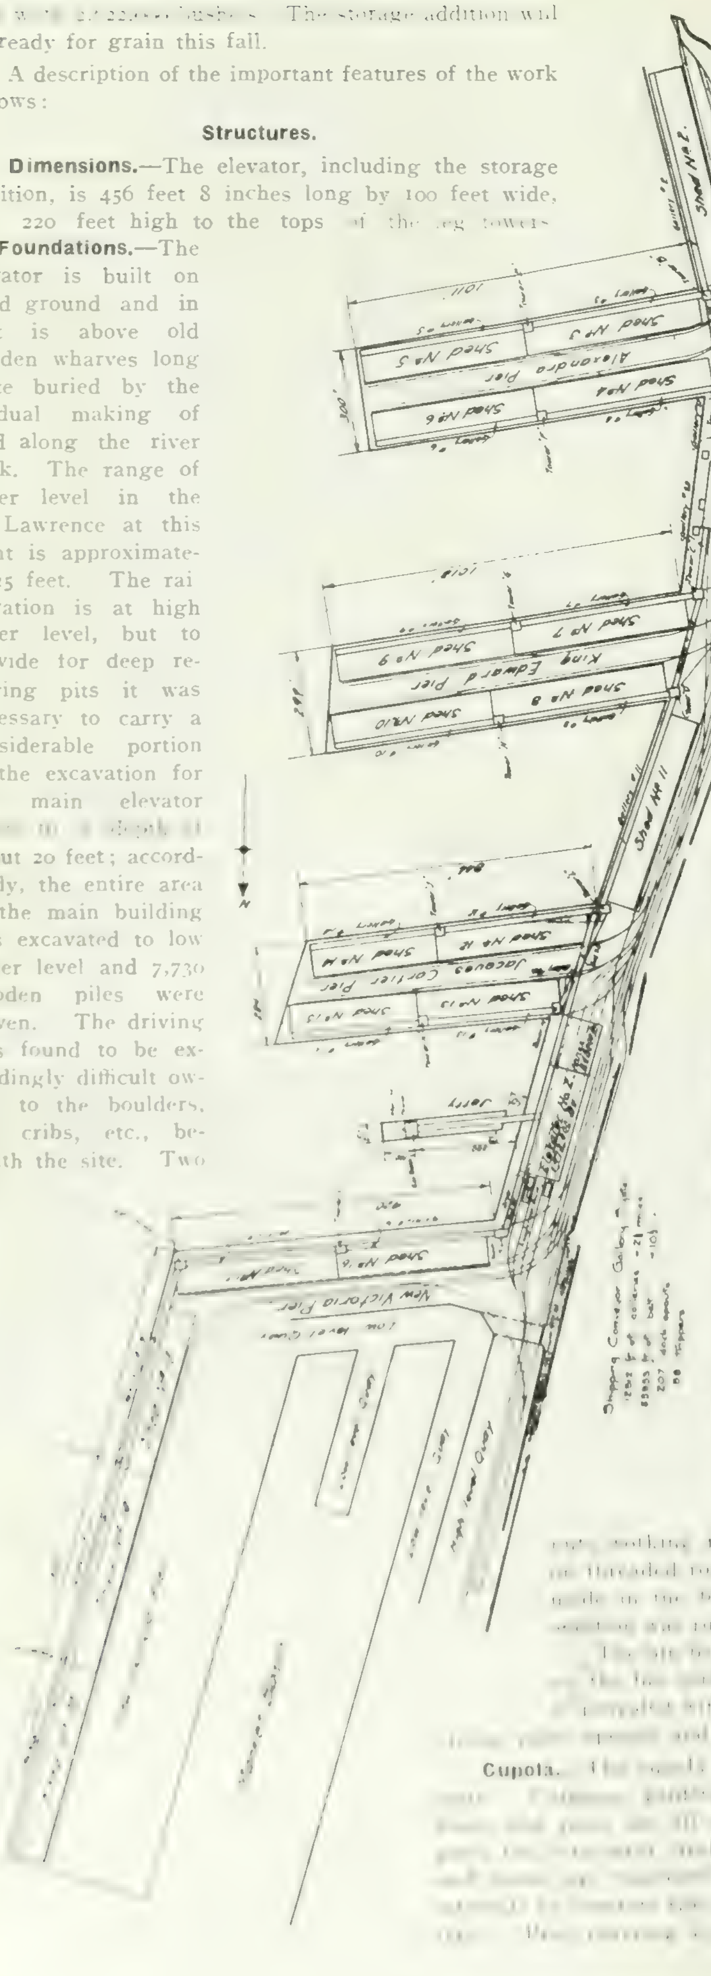
Foundations.—The elevator is built on filled ground and in part is above old wooden wharves long since buried by the gradual making of land along the river bank. The range of water level in the St. Lawrence at this point is approximately 25 feet. The rail elevation is at high water level, but to provide for deep receiving pits it was necessary to carry a considerable portion of the excavation for the main elevator [illegible] to a depth of about 20 feet; accordingly, the entire area of the main building was excavated to low water level and 7,730 wooden piles were driven. The driving was found to be exceedingly difficult owing to the boulders, old cribs, etc., beneath the site. Two large drivers with No. 1 Warrington steam hammers were employed. On top of the piles a reinforced concrete slab 3 feet 6 inches thick was laid, extending over the entire foundation area. An idea of the foundation problem may be gained when it is known that loads as high as 1,270 tons had to be carried on some of the columns.

Concrete piers and walls were built on top of the foundation slab and carried up to the track level. The track girders are of reinforced concrete, except over the receiving pits, where they are of steel. Boot tanks and track hoppers are of steel.

The foundations of the 850,000-bushel storage addition were differently treated. As there were to be no elevator legs, and consequently no boot tanks, in this portion of the elevator, the deep excavation necessary for the main elevator was not required. Consequently 1,535 reinforced concrete piles were used. These were of the Simplex moulded inserted type, with their tops about four feet below base of rail. Above them the foundation concrete was placed.

First Story.—Four railroad tracks extend through the entire elevator. The bin openings are 22 feet 6 inches above the tracks. The columns supporting the bins are of reinforced concrete, about 24 feet centres, in general, each way. Some of these columns are as large as 6½ feet by 5½ feet. They are surmounted by the heavy concrete girders supporting the bins. These main girders are 5 feet deep and 6½ feet wide. The first floor is of concrete except at hopper and grain openings, where steel gratings are employed. Curtain walls are of concrete, with a large area of fireproof windows. The track openings are closed by rolling steel doors.

Bins.—The bins are of reinforced concrete, are rectangular in form, and 86 feet deep. Bin walls are in general 8 inches thick. Bin capacities range from 6,800 bushels to 14,300 bushels; and the total number of bins is 278, exclusive of shipping bins. Along the water side of the elevator the upper portion of each bin is used as a shipping bin. An intermediate concrete bin bottom is placed about mid-height of the bin, the upper portion of the bin discharging to the shipping conveyors and the lower portion being used as an ordinary storage bin.



General Plan of Elevators and Galleries Grain Elevator No. 2, Montreal, Quebec.

Built by the John S. Metcalf Co. Ltd. for the Harbor Commissioners of Montreal.

The bins were constructed by the use of moving forms. The forms were raised by [illegible] working on jack castings attached to the forms, the nuts travelling on threaded rods set vertically in the concrete walls. Rapid progress was made in the building of the walls, the height of 86 feet in the storage [illegible] day and night work.

The bin bottoms are of reinforced concrete, in part supported directly on the bin girders and in part suspended from them. Each bin opening is equipped with a [illegible] turnhead, with rack and [illegible] from the floor above.

Cupola.—The cupola construction is a [illegible] example of reinforced concrete. Columns, girders, floor and roof [illegible] bracing, [illegible] curtain walls, [illegible] are all of concrete. [illegible] in the case of machinery supports [illegible] used. The lower side of floor and [illegible] Curtain walls are [illegible] thick, supported at short intervals by [illegible] connecting to the floor girders. Windows are of fireproof type. [illegible] except at the leg towers, where the concrete is waterproofed and covering omitted. The cupola is 107 feet high above the bin walls, and 220 feet above the base of the rail. This means that there are very few, if any, higher reinforced concrete buildings in existence.

Above the storage addition the cupola is but two stories high, as the only machinery above those bins is the conveyers and spouts for filling the bins.

Marine Tower.—A marine tower for unloading boats is placed on a jetty projecting into the neighboring slip. The tower is so placed in order that two vessels may be unloaded simultaneously, one lying along each side of the jetty. The tower is 340 feet from the elevator. It is built of structural steel, this material being adopted instead of concrete because it is expected that, in the event of the Georgian Bay Canal being built and 600-foot vessels being brought to Montreal for unloading it may be desired to extend the jetty farther and move the tower to such a distance from shore that 600-foot vessels may be unloaded without interference. As the shorter jetty is, however, better adapted to present congestion in the harbor, it has been adopted until such time as the increased size of lake boats coming to Montreal shall require its extension.

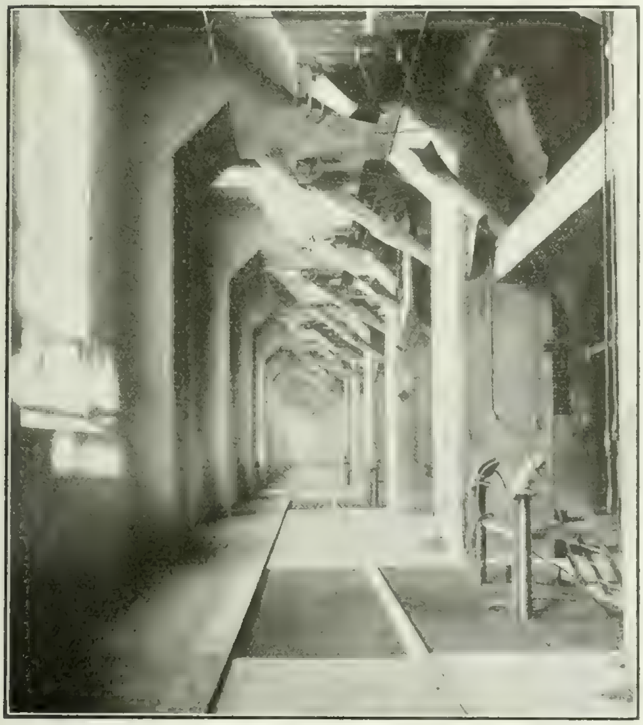


Fig. 2.—A View of the First Floor.

A steel gallery runs from the marine tower to the elevator, and contains the conveyer belts for taking grain received by boat to the elevator.

Shipping Conveyer Galleries.—Study of the accompanying diagram will show the extensive system of shipping galleries built and contemplated. Those already built in connection with elevator No. 1 were two miles in extent. Those to be added in connection with elevator No. 2 will bring the total to 2½ miles, using 10 miles of rubber belt. All galleries are of steel with concrete floors and roofs and corrugated steel side-covering.

Miscellaneous Structures.—A reinforced concrete building is provided for a grain dryer and its boiler plant, and a similar structure for the transformers and switchboard.

Equipment.

Receiving from Cars.—There are four receiving tracks, 24 track hoppers, and twelve receiving legs. Each leg is fed from two hoppers, one on either side, interlocking valves being used so that it is impossible for grain to reach the leg from more than one hopper at a time. Track hoppers are of large size, and a pair of power shovels is provided at each. Thus the unloading of a car on one side of the leg is independent of that on the opposite side, and unloading from both cars may proceed simultaneously, as the legs are of sufficient capacity (12,000 bushels per hour each) to quickly elevate the contents of either hopper as soon as the elevation of the contents of the other has been completed. The [illegible]

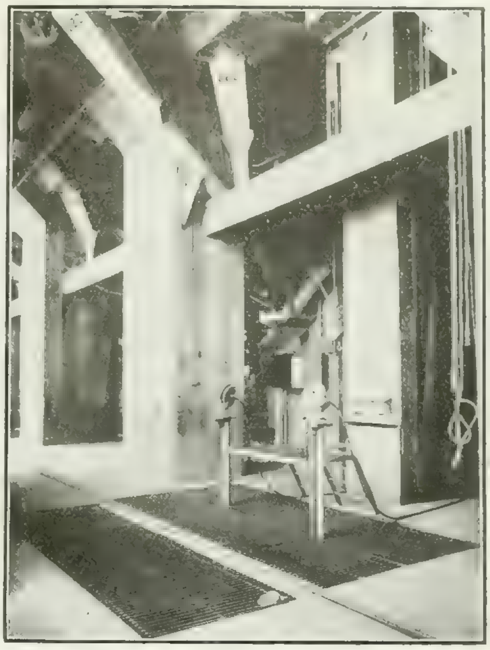

Fig. 3.—A Detail of the First Floor.

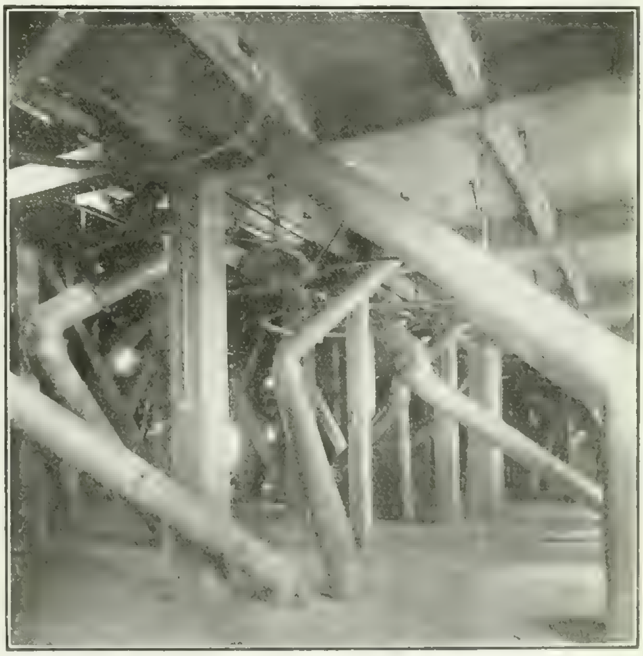

Fig. 4.—View of Distributing Spouts in Story Over Bin.

with the ordinary complement of men, and with extra men can better this in emergencies.

Cars are handled by heavy carpullers using ¾-inch wire cable.

Each receiving elevator discharges to a 2,500-bushel garner over a 120,000-pound Fairbanks hopper scale, whence the carload is sent by spouts, or belt conveyers and spouts, to the desired bin.

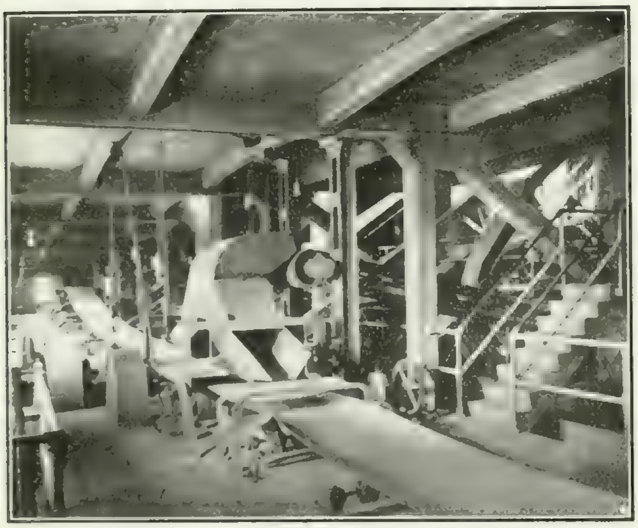

Fig. 5.—Belt Conveyers in Second Story Over Bin.

Receiving from Boats.—The marine tower is equipped with two marine legs, each of 20,000 bushels hourly capacity on the dip. One leg operates on each side of the tower, so that two boats may be unloaded simultaneously. The grain from the legs is weighed by two pairs of 6,000-pound Fairbanks continuous automatic weighing machines. Complete ship shovel and clean up shovel apparatus, operated by [illegible]

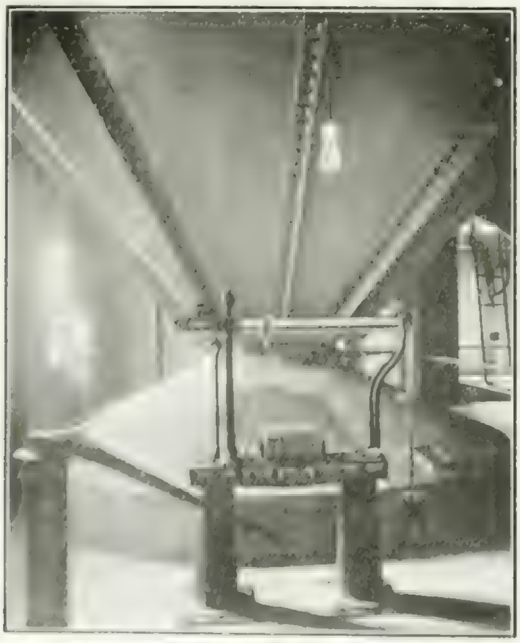

Fig. 6.—View of 2,000-Bushel Hopper Scale.

[illegible]

[illegible] constructed.

The 40-inch belt conveyers carry the grain to the elevators, where two lofter legs elevate it to the cupola. There a system of 40-inch conveyers distributes it to the double-jointed spouts leading to the bins.

The maximum hourly capacity for receiving from boats will be 40,000 bushels.

Distributing.—Two reversible longitudinal conveyers in the cupola receive from the scale and distribute grain longitudinally of the elevator.

Cleaning.—While Montreal is not a cleaning point, two large steel cleaning machines are provided for emergency cleaning and separating.

Shipping to Cars.—Four carloading spouts are provided so that cars may be loaded if desired. This sometimes becomes necessary in order to get grain to a winter port farther east after the port of Montreal has closed.

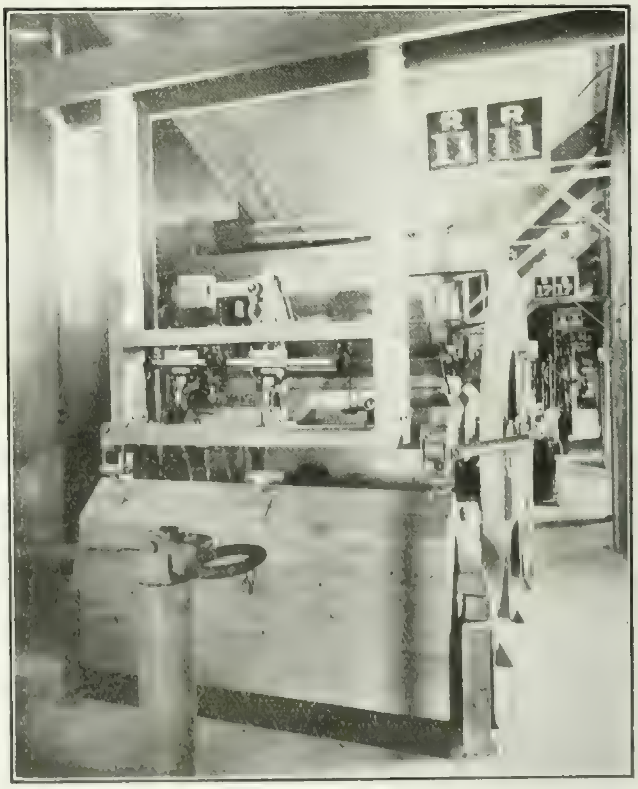

Fig. 7.—Automatic Weighing Machine, 5,000 lbs. per Draft.

Shipping to Ocean Vessels.—In connection with elevator No. 1 the shipping conveyers served 14 vessel berths on King Edward, Alexandra and Jacques Cartier piers and the neighboring shore wharves. Five berths are being added on the new Victoria pier.

The wide shipping gallery of elevator No. 2 contains six shipping conveyers. Two will extend north to serve the Victoria pier, and four will run south to connect with the conveyers to the present 14 berths. It will be possible for either elevator to ship to any of the nineteen berths.

The shipping system of elevator No. 2 will be served by five shipping legs, each with a capacity of 18,000 bushels per hour. The total shipping capacity of elevator No. 2, starting with the shipping bins full, will be 90,000 bushels hourly for ten hours.

Grain for shipment by boat is weighed through five pairs of 5,000-pound Fairbanks automatic weighing machines, each provided with automatic registers, printing devices, and electrical counters in the weighman's office. As shipping to boats and receiving from boats are continuous operations, automatic scales are used for this work, but as it is necessary in receiving from cars to keep each car weight separate, hopper scales are employed for car receipts.

Drying.—A Hess drying plant with a capacity of 5,000 bushels per day is included in the equipment. This has a separate leg so that interference with the main receiving and shipping legs is avoided.

Power.—All power is supplied by electric motors of the induction type. In the elevator, marine tower and the new shipping galleries the motors number 80, and total 4,680 horse-power.

An ingenious and efficient system of electric signals controls the operation of elevator legs and shipping conveyers. When the extent of the shipping system is remembered, and the interconnection of the two elevators, it will be seen that the signal system, particularly for shipping, must be instantaneous and sure; its design was accomplished with credit.

The harbor commissioners' grain storage and shipping system will now consist of: Two grain elevators with two marine legs each, and a conveyer system by which grain can be delivered from either elevator to any of 19 steamer berths. Everything is of fire-proof construction and all machinery is electrically driven. There is a storage capacity of 3,620,000 bushels and contemplated extensions for 3,790,000 bushels more; total, 7,410,000. Grain may be received from cars at a rate of 33,000 bushels per hour and at the same time from boats at a rate of 55,000 bushels per hour.

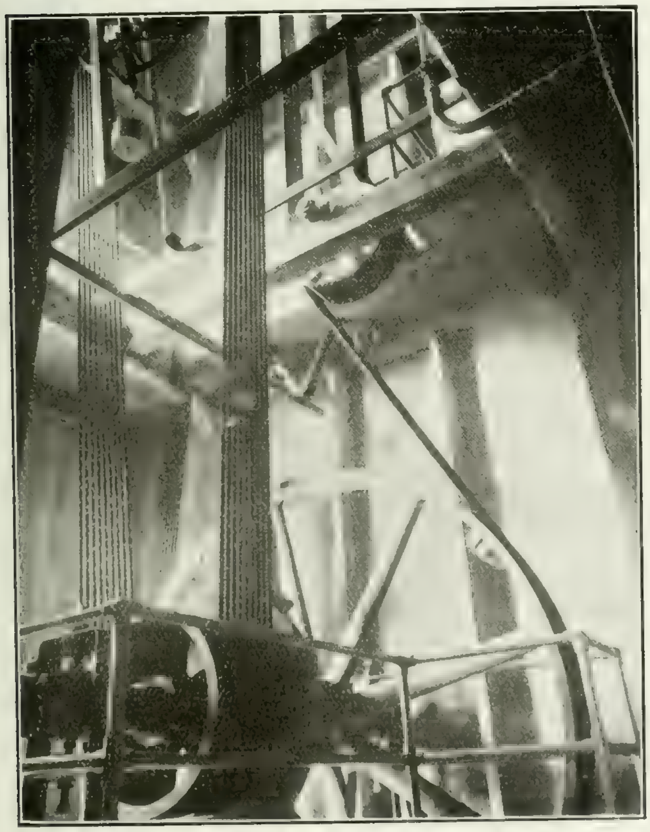

Fig. 8.—Drive to Receiving Elevator Leg.

Grain can be shipped by conveyer system to ocean steamers at their regular berths at a rate of 150,000 bushels per hour, equal to 4,500 tons per hour. It is possible to deliver grain to five steamers at the same time at a rate of 30,000 bushels per hour each, or it is possible to deliver to 10 steamers 15,000 bushels per hour each at the same time.

The present conveyer system comprises two miles of conveyer galleries and over eight miles of rubber belting. In addition to this there is under construction another half mile of gallery with two miles of rubber belting.

The constructing engineers for the Montreal harbor commissioners were the John S. Metcalf Company, Limited, Montreal, under Mr. F. W. Cowie, chief engineer. This company were also the designers of the conveyer system in connection with elevator No. 1.

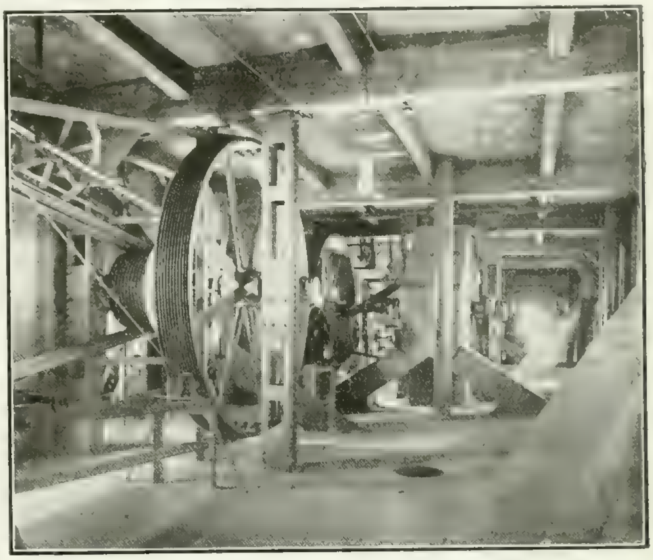

Fig. 9.—View of Top Floor Showing Elevator Heads and Drive.

It is easy to say that this building or that building is the best ever built, and that this elevator or that elevator can handle more grain than any other; the harbor commissioners responsible for the new work, Messrs. Stephens, Ballantyne and Geoffrion, with Mr. David Seath, secretary, are content to let the elevator and accessories speak for themselves.

◆

PHYSICAL PROPERTIES OF CONCRETE.

The National Bureau of Standards of the United States in its general investigation of structural materials is engaged, among other things, in the determination of the physical properties of concrete. At the suggestion of engineers and others, the Bureau of Standards is investigating the cause of cracking in concrete structures, where the necessity for expansion and contraction joints is questioned. For this purpose, reference marks were placed on some of the typical old and new concrete work in Wayne County, Michigan, also at Greenwich, Connecticut. Measurements will be taken from time to time during the summer and winter to determine the expansion or contraction in the concrete caused by temperature variations and the changes of volume which take place during the hardening of the concrete. Similar reference marks are being placed on the lock walls of the Panama Canal and various other structures, from which valuable information will be obtained.

◆

Steel on the Tofield-Calgary branch of the Grand Trunk Pacific has been laid as far south from the main line as Irricana, and that the grade is now ready for entry into the latter place. A bridge at the Bow River, about four miles out of Calgary, is likely to delay track laying a little. This bridge is of steel construction and is to be erected by the Canadian Bridge Company.

POWER PLANT OF MOUNT HOOD COMPANY.

The power plant of the Mount Hood Railway and Power Company (now owned by the Portland Railway, Light and Power Co.) is one of a number of similar plants that have been built within the last few years to supply light and power to Portland and other near-by towns and cities in Western Oregon and to Vancouver and other towns in Washington. The following description of the plant, now nearing completion, is given by W. P. Brereton, chief engineer of construction:

A dam approximately 100 feet high in the middle and about 400 feet long is in course of construction across the Big Sandy River for the purpose of diverting water. The water thus diverted is carried for a distance of about 9,700 feet with about 18-foot fall through 800 feet of timber flume having a capacity of 700 second feet, 4,200 feet canal of trapezoidal section, and then through a tunnel approximately 4,700 feet long, about 11 feet by 11 feet cross section, driven through the hill, and discharges into the Little Sandy River.

About 200 feet below this point of discharge a diverting dam has been built about 14 feet high and about 115 feet long. The water thus diverted is carried for a distance of about three miles along the hillside with a 34-foot fall, through a timber flume, having a capacity of 800 second feet, discharging into a reservoir. This reservoir has an area of 180 acres with a total capacity of 138 million cubic feet, and is formed by constructing an earthen dyke about 40 feet high on three sides and using the hillside for the fourth side.

Located inside this reservoir is the intake for the three penstocks, and for this purpose the ground has been excavated down to the lowest point of the reservoir, and the intake and gatehouse for the three penstocks built up of concrete from this elevation to a height of about five feet above high water, or about 40 feet high. The forebay is about 300 feet wide, excavated down to the lowest elevation of the reservoir. A spillway is provided in this dyke for taking care of 800 second feet with a 2-foot 6-inch depth of water on the crest.

Suitable racks and stop logs are provided at the entrance of each of the three penstocks and the penstocks themselves are controlled by 10-foot butterfly valves operated by hand or electric motor controlled from the power house.

Two penstocks, each 9 feet in diameter, are being carried through tunnels from this intake for about 400 feet, [illegible] and at that point a suitable standpipe, 5 feet in diameter, and tank is provided for each penstock. These 9-foot penstocks continue down to the power house. A third 9-foot penstock is being laid from [illegible] for future extension.

The general design of the pipe line is as follows: The [illegible] tunnelling in place having to be resorted to owing to the nature of the ground, [illegible]

[illegible]

[illegible]

[illegible]

Height, open, 23 feet 1⅞ inches, centre of valve.
Height, closed, 18 feet 5⅞ inches, to top of loop.
Face to face, 40 inches.
Diameter of cylinder, 40 inches.
Width over all, 37 inches by 73¾, bonnet flange.
Diameter of spindle, 4¾ inches.
Weight, 37,634 pounds.
Diameter of flanges on the run, 66 inches.
Thickness of flanges on the run, 3 inches.
Drilling, 48½-inch bolts on 62½-inch between centres.
Size of by-pass valve, 8 inches.
Working pressure, 140 pounds.
Test, 250 pounds for one hour.
Height over all from bottom of flange, closed, 21 feet 2¾ inches.

Each valve is located at the end of a steel penstock supplying water to turbines in the power plant near Bull Run River, Bull Run post office, about 27 miles from Portland, Oregon. The body, bonnet, disc, cylinder and piston are made of Ferrosteel, and the piston is equipped with bronze rings. The guide ribs in the bonnet and body are bronze lined, and the discs are furnished with bronze rollers. The stems are steel, encased in bronze tubing.

Twenty-four-inch branch pipes are taken from one 78-inch pipe on each pipe line for the purpose of supplying the exciters, these branches being governed by 24-inch gate valves. The 78-inch pipe lines are safeguarded both by automatic relief valves on the turbines and also by bursting plates on the pipes themselves.

The power house is being built on the south bank of the Bull Run River, the turbine tail races discharging directly into the river. The building at present being constructed is of reinforced concrete 191 feet long by 47 feet wide; height to crane rail 30 feet, one end being made temporary. Below the floor proper and above the tail races is a basement 11 feet high suitable for small machine shop, repairs, etc.

On the power house floor proper is located the machinery.

The switchboard and control gallery are located on the back wall of this building 11½ feet above the floor. Sufficient length of rails is laid into this building to enable a car to be brought in and unloaded by the crane, a 35-ton, three motor electric crane being provided for this purpose.

Immediately at the back of the power house is a small concrete building about 57 feet long by 33 feet wide in two floors, the lower floor, which is 12 feet high, being used for low tension switch room, and the upper floor, which is 12 feet high, being used for switches and bus structure. Direct access can be had from the control gallery in the power house with this latter room. The railroad track to the warehouse and depot are laid across the roof of this building.

Immediately behind this building, and on the same level as the roof of this switch room, is the transformer building, consisting of a room 18 feet wide by [illegible] feet long, equipped with a 40-ton, 3-motor electric crane for unloading the transformers from the cars, rails being laid right into the building for this purpose and also for repairs. Immediately behind this building, and adjoining it, is the transformer room proper in which will be installed seven transformers, each of [illegible] capacity. All the space above the transformer is taken up with the necessary bus structure [illegible]. All the necessary [illegible] is carried by pipe into the tail race.

In the [illegible] Type B Francis [illegible] Works, each of [illegible] oil pressure governors, pumps and tanks. These turbines are connected to steel penstocks through 60-inch hydraulic valves and work under a static head of 320 feet. Directly coupled to the shafts of these turbines are two Westinghouse alternating current revolving field generators, each 3,750 k.v.a. 3-phase, 60-cycle, 6,600-volt, 514 r.p.m.

One 6,400 horse-power horizontal, Francis type, single discharge turbine, manufactured by the Wellman-Seaver-Morgan Company, complete with N.S. 10 Lombard hydraulic governors, pumps and tanks, etc. This turbine is connected to a steel penstock through a 54-inch hydraulic valve and works under static head of 320 feet.

Direct coupled to the shaft of this turbine is a Westinghouse alternating current, revolving field generator 3,750 k.v.a., 3-phase, 60-cycle, 6,600-volt, 514 r.p.m. The fourth unit under option will be similar in all respects to the 6,400 horse-power Wellman-Seaver-Morgan, Westinghouse set.

Two 24-inch exciter wheels, manufactured by the Platt Iron Works, developing 300 horse-power each, when operating at a speed of 690 r.p.m. under 320-foot head, direct coupled to two 150 kw. Westinghouse direct current generators, 250 volts, 600 amperes, 6 poles, compound wound.

The engineers on this contract are Smith, Kerry and Chase, of Toronto, Canada. The chief engineer is W. P. Brereton; assistant engineer, J. S. Bodkin; chief draftsman, J. R. Carroll.

◆

HISTORY OF AN OLD IRON BRIDGE.

In a recent bulletin of the American Railway Engineering Association Mr. George K. Lowell, general manager of the Detroit, Toledo and Ironton Railway, gives a brief history of the Iron Railroad, together with the original construction of the Iron Bridge, spanning Storms Creek, on the line of the Iron Railroad, two and one-half miles north of Ironton, O.

Construction of the Iron Railroad was originally commenced in the year 1849, and the line was completed to the Vesuvius Mines, about six miles north of Irontown, during the year 1850. The track was laid with strap rail laid on wooden stringers, and the stringers laid on cross-ties spaced six feet apart. John Campbell, John Peters and others, of the Ohio Coal and Iron Company, were the original founders of the Iron Railroad.

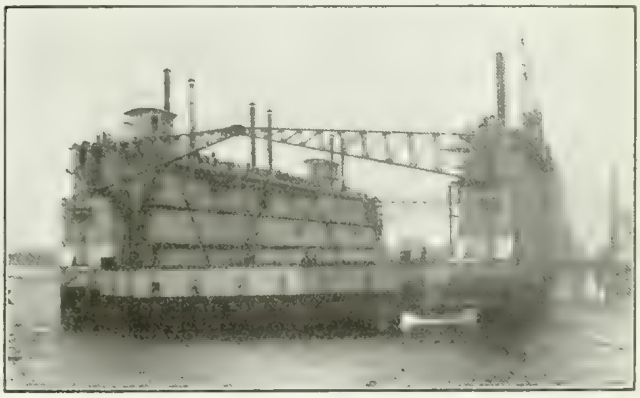
In the construction of the Iron Railroad it became necessary to span Storms Creek, two and one-half miles north of Ironton. In the original construction of the Iron Railroad, Storms Creek was spanned with a wooden trestle bridge, 97 ft. in length, but during the year 1857 the structure was considered insufficient to carry the increased loading of the road's equipment, and it was decided to construct an iron bridge of larger capacity, and more safe for the operation of the railroad. Thomas W. H. Moseley, a civil and constructing engineer, of Kentucky, was called upon to prepare a plan for the construction of a wrought-iron bridge to be placed on the site of the wooden structure spanning Storms Creek. The plans were prepared for what is known as Bowstring Construction Iron Bridge, patented February 8th, 1857, and constructed by Moseley & Company, of Cincinnati, O., in the year 1859, the bridge being constructed for the loading of 2,000 lbs. per linear foot, live load.

In the year 1905, the Detroit, Toledo and Ironton Railway, successors to the Iron Railroad, increased the weight of its locomotives and cars, and it was necessary to strengthen this bridge by placing timber trestle bents under the floor or track system. With this addition, the bridge, as originally constructed, is still in use, and over it passes as heavy tonnage as on any road in this section of the country.

THE MONTREAL FLOATING DOCK "DUKE OF CONNAUGHT."

There has recently been delivered at Montreal the floating dock "Duke of Connaught," which has been built by Messrs. Vickers (Limited), of Barrow-in-Furness, England. In *The Canadian Engineer* of August 15, 1912, we gave some details of the launching of the dock. We are now able to present a more complete description. This dock, one of the largest yet constructed, is capable of accommodating the largest existing vessel of the British navy. It is of the double-sided, self-docking type, and consists of a pontoon, or lifting portion of the dock, and two parallel side walls, built on to and forming part of the same, and the whole length is divided into three complete and separate sections, which, when bolted together, form the complete dock. These sections are so arranged that when the dock is separated into its three parts, any two of them can dock the remaining third between them. For this purpose each section is fitted with its own independent pumping machinery, so that it can also act as an independent unit. The general dimensions of the dock are as follows:

Length over platforms, 600 ft.
Length over pontoons, 550 ft. 6 in.
Width overall, 135 ft.
Depth of pontoon at centre, 17 ft.
Length of side walls, 470 ft. 6 in.
Height of side walls above pontoon dock, 42 ft.
Width of side wall at base, 17 ft. 6 in.
Width of side wall at top, 12 ft. 6 in.
Clear width between roller fenders, 100 ft.
Draught of vessel, 27 ft. 6 in.
Lifting capacity, 25,000 tons.



View of Dock.

The construction of the dock is such as to make it suitable for lifting a modern British battleship, the pontoon dock being specially stiffened to allow it to support a large portion of the weight of the vessel on side or bilge, as well as central keels. The pontoon consists of a rectangular structure plated in all round with the exception of the portion of the deck which comes directly under the walls, and stiffened internally by longitudinal and transverse girders. The two end sections have their outer extremities built in the form of a point or bow terminating in a working platform carried on plate and braced girders. The bottom plating, except under the walls, is arranged to run transversely, and is connected to the plating of the sides and points by chine angles; the top or deck plating, similarly arranged, is connected to the face of the side wall by chine angles. The pontoon is divided into four compartments by three longitudinal intercostal water-tight plate-bulkheads. Transversely the pontoon is divided into 54 bays, 20 in the central section and 17 in each end section by transverse girders, consisting of plate-bulkheads. In the compartments under the walls the plate-girders are replaced by special lattice-girders. In addition to the bulkheads, the deck and bottom platings are stiffened by means of a series of longitudinal frames which run fore and aft over the length of the pontoon, intercostal between the transverse girders. In addition to the transverse lattice-girder under the wall, intermediate transverse ordinary frames are fitted, 2 ft. 6 in. apart, and are prolonged upwards, forming the ordinary frames of the walls. The central bulkhead between the transverse girders is stiffened by vertical "breathing" plates, which are well stiffened and connected to a longitudinal curtain plate. Outside this framing of breathing plates and longitudinal curtain plate, the pontoon deck and bottom are stiffened by longitudinal framings consisting of angles, connected to the transverse bulkhead stiffeners by gussets and diagonals. These framings extend to the line of the face of the wall. In the centre section several of these frames are provided with plates riveted to them, to take the load from the side keel-blocks. The intermediate longitudinal bulkheads are formed of vertical plates, intercostal between the transverse girders, to which they are attached, as they are also to the top and bottom plating. To facilitate the complete withdrawal of all water in the pontoon, shallow troughs are fitted, which form a gutter. The walls of the dock are placed horizontally and have a batter on the face or inside wall. The top deck of the walls is plated longitudinally, and is connected to the side plating by double-chine angles. An engine-deck, on which is placed all the machinery of the dock, is fitted about 16 ft. below the top deck, and is arranged water-tight. Each wall is divided, in addition to the joint chambers, into ten water-tight divisions by plate-bulkheads, coming in line with the bulkheads in the pontoon, of which they are a continuation. At each end of the wall a docking land is formed, on which the central portion can rest when being self-docked. The framing of the walls is of two types, braced and ordinary. In line with the transverse girders of the pontoons, of which they form a continuation, the frames consist of single angles stiffened by vertical web-plates, the front and back plates being cross-connected by a series of diagonals and gussets. The ordinary frames of the walls consist of single angles back and front, cross-connected by a series of horizontal struts. Special stiffening is fitted in way of machinery. About one foot below the top deck a running deck is provided for enabling ropes to be easily handled and run from one end of the dock to the other outside the stanchions. Timber-heads and such fittings required in berthing vessels are fitted on this deck. At a distance of about 15 feet and 29 feet respectively below the running deck, two further stages, known respectively as painting and shoring stages, are provided. Each end of the central section and each square end of the terminal sections are provided with a joint [illegible], by means of which the sections can be joined together or parted. For the purpose of dealing with commercial vessels, which ordinarily will not have the length or [illegible] of the [illegible], the dock has been designed so that it can work when required in two independent units of unequal size, and to facilitate the rapid [illegible] of the two portions [illegible] docking [illegible] [illegible] are [illegible] at the level of the keel-blocks. The pumping machinery of the dock is driven by steam generated in boilers carried on the dock itself. Each section of the dock has its own complete pumping installation, and each [illegible] of two boilers and two engines and [illegible] located in specially constructed chambers in one of the walls. The pumps, which are of the centrifugal type, [illegible], are coupled to a main drain at the bottom of the dock, which is extended over practically the whole length of each section. From the main drain compartment pipes are led to each separate water-tight division of the dock. Each compartment is governed by its own separate valve, and the main inlet pipe and pump discharge pipe are governed by separate screw-down valves, and in addition have each a non-return flap-valve on the outside. The compartment valves of each section of the dock are all operated from a valve-house placed on the top deck of each section, by means of the Westinghouse electro-pneumatic system, which is based on the principle of operating presses by compressed air and controlling the same from a distance by means of valves operated by an electro-magnet. Each valve house is in telephonic communication with its respective engine-room and also with the others when the dock is working as a single unit. Each section of the dock is also provided with a direct-acting steam-pump, arranged to draw from the sea, and capable of providing a full stream of water for fire service or washing down vessels. These pumps are also connected to the main drain, so that they may be used as a drainage service for completely emptying the compartments. Two similar steam-pumps are also fitted on the opposite wall of the dock.

Steam heating is provided to prevent water in the compartments from freezing, and also for the mechanism that could be affected by frost. Each water-tight compartment is provided with the Gardner and Ferguson indicating system, to show, in the valve house, the level of the water inside it.

Similar gear is also provided for indicating the draft of water over the keel-blocks. The dock is provided with eight steam capstans, four on each wall. The spindles of the capstans are carried down vertically to the level of the pontoon deck, where, in a small chamber in the wall at this level, cable-lifters are fitted, so that the mooring cables may be hauled in or paid out when the dock is being moved about. Donkey boilers are provided on the wall remote from that in which the main boilers are fitted, to provide steam for the capstans and fire-pumps fitted on that wall. On the top deck of this wall a three-ton electric travelling gantry crane is fitted and arranged to traverse the whole length of the wall. At both ends of the combined dock a pair of flying gangways or swinging bridges are fitted, affording access from one wall to the other.

The dock will be lighted throughout the machinery compartments by means of electric lamps. The outside lighting consists of bracket standards, each supporting a cluster of lamps. Box terminals are also fitted on the walls, from which lamp clusters can be taken by flexible leads for lighting any particular portion of the ship on the dock. Electric current will be supplied through cables from the shore.

The dock is provided with the usual bollards and timber heads. Roller fenders are also fitted to protect the walls of the dock from an entering steamer. Eight mechanical side shores, four on each wall, are provided. These can be screwed in or out by a standard fitted in the top deck. Keel-blocks, side or docking keel-blocks, and bilge blocks are provided; the latter are arranged to pull in or out to suit the shape of the ship when she has taken the keel-blocks. The keel-blocks are strongly made and closely spaced, to enable them to take the weight of the heaviest and most modern ironclads. Ladders are fitted leading from the upper deck of the dock to the pontoon deck, and also into the various compartments of the dock. Suitable hand-rails are fitted all round the top deck. Ventilation by means of cowl and downcast pipes is arranged to each boiler and engine room, and also to the interior of the walls. A valve-house large enough to contain the valve-control table and the recording instruments is fitted on the top deck of each of the three sections, each valve-house contains the apparatus necessary for controlling the valves of its own particular section.

IRRIGATION LESSONS FROM THE OLD WORLD.*

By Sir William Wilcocks.

Living among Arabs for the last thirty years, I hesitated at first to say anything at this meeting, as they greatly respect silence in the East. "O man, God gave thee two feet, two hands, two ears, two eyes and one tongue, know thy destiny." However, I have remembered that I was born sixty years ago in a tent on an irrigation canal in Northern India, and have spent my life in those arid lands where, in ex-President Roosevelt's words, it is water and not land which measures production; and that therefore I might say something to-night on the subject of eastern irrigation.

The spirit of irrigation in the East is the spirit of the homestead. The intense cultivation, the need of many heads and many hands to weed, to care after live stock, to gather in the varied harvests, to manipulate delicately and to trim carefully, justify one in slightly changing the words of the Psalmist and saying that "irrigation and marriage meet together, children and prosperity kiss each other." Children in towns are a source of expense, on irrigation farms they are a source of wealth. In Egypt children four and five years old take out huge buffaloes to pasture and control them by a string tied to the horns and passed round one of the ears. Boys of eight and nine lead out sheep and guide them so that they clean the land of weeds and confirm the truth of that old English saying that "the feet of sheep are shod with gold." Girls and women cut and bring in clover, pick cotton, clear rice fields of weeds, prepare the fuel and look after the house. All are busy from morning to evening, and the larger the number of hands, the cleaner the crop and the more plentiful the yield. In the old world east a man is not considered fit to sit down among respectable people if he has passed a certain age and is unmarried. And although I did not know it then, I know it now, that it was this spirit of irrigation which prompted me in my younger and more romantic days to write down on the first page of my note book those delightful lines of Burns:

> "To make a happy fireside clime
> For weans and wife,
> Is the true pathos and sublime
> Of human life."

I know that in the younger West, book learning is considered the royal road to wisdom, even though it is only one child in ten who really benefits while nine are being brought up on indigestible mental food. In the old East, the brilliant children are allowed to learn books, while the others are brought up in intimate knowledge of their parents' professions. On farms where all the laborers are members of the house, there are none of the strikes, and none of the unrest in which the West lives and moves and has its being to-day. I was not surprised, therefore, to find that the home-loving Mormons had the only cozy, comfortable and settled villages I saw in Alberta. Raymond, Macgrath and Cardstone had a settled, sitting-down look about them which reminded me of villages in Egypt and India. I know that Mormonism has few friends in this country, but in all matters we should, I think, remember Shakespeare's sage words:

> "There is some soul of goodness in things evil
> Would men observingly distil it out."

We can even learn something from the Mormons, who are the nearest people here to the irrigators of the old eastern world. Their farmsteads are clustered together and they thus secure in the country some of those privileges which make town life so attractive. A man walks a little farther to work, and the ploughman homeward plods his weary way along a longer track, but then life is more sociable once he gets home. I wonder how many people in towns would drop in of afternoons and see each other if everyone had to walk across a square mile of country or half a square mile to see his or her neighbor. The solitary, homeless-looking houses which lay scattered over the bare veldt looked more like rogue elephants living their unsociable lives than anything I have seen in my life. Where I was straining my eyes for bunches of children, I saw only bunches of horses or bunches of pigs. And yet, you pay ten shillings a day for labor. Bunches of sturdy boys and girls are worth their weight in gold. While you people here are asking for colonists from home, the East produces its own colonists, better suited to the country and infinitely cheaper than imported labor.

A small, well-worked farm with irrigation pays much better than a large farm which cannot be kept in good tilth; and here comes the difficulty in this country with its severe winters. A farmer, however small he may be, could not exist in a farm house which cost less than, say £200 to build. Now, £200 spread over 160 acres is £1. 4. per acre, and spread over 40 acres is £5 per acre. It is the cost of the farmsteads which is the serious side of small farms in England and it is still more serious here. Agitators in England abuse both the English landlords and the so-called stupid agriculturists who stand by them, but the agriculturists know that it is not the price of the land, but the cost of the farm buildings which stand in the way of small holdings. Big holdings in irrigated land will be eaten up by their own weeds, and the only way to manage is with small holdings and comparatively expensive farm buildings. In Alberta the Canadian Pacific Railway charges very moderately for its irrigation water, but the price of the land is high for small holdings, and the rate of interest for borrowed money is excessive. Government land banks with very moderate rates of interest as they have them in paternal (falsely called retragrade) countries like Russia, are one of the needs of irrigated Canada. Such money would only be lent to bona fide settlers making themselves at home on their lands, and not to the "caterpillars of the commonwealth," who only buy either to half develop and then sell at a profit and clear out after skimming the cream off the lands by exhaustive crops, or to sit and wait for the unearned increment.

Rotation of crops and, whenever possible, the keeping of live stock, is the life of irrigated lands in the East. Cereal crops are always followed by leguminous crops. The leguminous crops are the mortal enemies of the weeds of the cereal crops and vice versâ. Good leguminous crops provide all the nitrogen required, while small quantities of superphosphate insure heavy yields of corn and tend to hurry up the ripening of the crop. Irrigated land in Egypt has been heavily cropped every year, and over large areas twice every year, and is as rich to-day as it was 7,000 years ago. Rotation of crops has secured this, backed up always with as many cows, sheep and poultry as the land can carry. The average holding of a well-to-do family in Egypt is two acres. When there is no work on the farm some members of the family are always working at earthwork or porterage somewhere. An entire family of men, women, children and a few donkeys will take a quarter of a mile of earthwork digging somewhere and finish it at some fixed rate and time. Seeing such folk one understands why Abraham's wealth was described as consisting of "man servants and he asses, female servants and she asses."

---

* Paper read at the Sixth Annual Convention of the Western Canada Irrigation Association, Kelowna, B.C., August 13th to 16th, 1912.

Every canal bank in India is a minature forest, and if the government forest department out here were to cover the banks of the canals in the bare and naked prairies with poplars, willows and suitable trees, the country would begin to look quite homelike. Wherever trees are growing in shingle they seem to flourish, and it has struck me that if holes some four feet deep were made with jumpers and filled with shingle and loose top soil and trees planted in them and watered once or twice they would soon have their roots comfortably housed out of the way of the frost. Lord Kelvin has proved at Glasgow that small meshed wire netting round a farmstead makes a better wind-break than any masonry wall, however high, and delicate plants can live behind it. I have promised my friends here to go to Glasgow as soon as I return to Liverpool and send them out full details of the netting Lord Kelvin has used. It might help many a farmer to secure a decent belt of trees round his farmstead.

All the regulating works on the rivers are much bolder here than in the East. When the welfare of millions of people is concerned we cannot afford to run any avoidable risks. Time alone can tell whether the boldness of the engineers here is justified or not. No one here has seen the tragedies the East has witnessed. In the Euphrates Valley I have walked down a canal 250 miles long, 400 feet wide, and 15 feet deep, which irrigated probably 1½ millions of acres of land, and where it is conjectured that over two millions of people must have died of hunger in a year or two when the head works holding up 30 feet of water on the Tigris River were swept away. By the time Canada is as densely peopled as that, the engineers will play for safety as we do in the East. None of our works on irrigation canals in the East are temporary. All the works are as solid and permanent as money can make them. We all say that the original works can be cheaply built in the dry; once the canal has begun to carry water and establish water duties, works are costly indeed and attended with risks.

The question of water rights has been settled in the East from the remotest antiquity. Water has attached to it duties as well as rights, and the state is the sole proprietor of every drop of water which flows in any stream, and of the channel in which the water flows, and it never concedes its rights to anyone. When Victor Emmanuel amalgamated all the Italian states, his government was face to face with hundreds of varieties of water rights by individuals and corporations. An ordinary man would have hesitated, but Count Cavour was no ordinary man. He was one of those strong men a country about to become great produces, just as coming events cast their shadows before. With a stroke of the pen the water was made the property of the state after the wise Eastern way, and commissions appointed to examine [illegible] holders of rights [illegible] prosperity to Count Cavour's action. If the government of British Columbia were to declare itself owner of all water rights and [illegible]

In the East to-day all the land needed for future canals and drains is taken up and the works begun before irrigation water is allowed to enter the canals. If the drainage system of a country is suited to a rainfall of 16 inches and you make the rainfall equal to 40 inches by artificial irrigation you must make provision for this extra water in the drainage lines. When a man buys a plot of land here he signs an agreement to allow his neighbors a right-of-way for their irrigation water. He should also sign an agreement to allow his neighbors a right-of-way for their drainage water. It is only in this way that you will be able to exorcize the demon of alkali efflorescence which is ever ready to enter the plot of land out of which the demon of drought has been driven by artificial irrigation.

In the East the irrigation farmer levels his land with a care and skill which testify to his long experience of the value of an even grade for securing the maximum of yield from the minimum of water. The economy of water to be gained by good surface tilth the East is learning from you western farmers.

Mr. President, ladies and gentlemen, I thank you for listening to what I have had to say on this subject of irrigation, the oldest and youngest science of the world. Here, in this new country, in this 20th century, A.D., the words of this most ancient poem are as true to-day as they were over fifty centuries ago in far distant Babylonia:

"O thou river, who didst bring forth all things
When the great Gods dug thee out
They set prosperity on thy banks."

◆

WATER POWERS OF BRITISH COLUMBIA.

The water-power resources of British Columbia are being investigated by the Commission of Conservation, and the resulting information is to be published, as soon as it can be made available, in a report to be entitled, "The Water-Powers of Western Canada," which the Commission have in course of preparation.

The securing of even preliminary field information in a territory like British Columbia requires much more time than in a country less mountainous. Good progress, however, is being made. The British Columbia Government's Department of Lands, under the Hon. W. R. Ross, has made a substantial contribution to assist the Commission in its water-power research.

This practical assistance from the Department of Lands has enabled parties to be detailed for investigation on the mainland coast. These parties have been in the field since the beginning of August, and are being directed by the Commission's engineer, Arthur V. White, who is in charge of the work.

The Commisison has three field parties investigating the watershed of the Fraser River above Lillooet, extending to Tête Jaune Cache and westward beyond the Fraser Lake district.

[illegible] a map of British Columbia and asks what are the power possibilities of the interior of the [illegible] After the Commission has completed its present reconnaisance survey, it will be possible, first, to form some reliable conception of the water-powers of British Columbia south of the line of the [illegible]

THE HARDINGE CONICAL MILL FOR FINE GRINDING.

By H. W. Hardinge.*

Crushing is not confined to the efforts of the metallurgist alone, but it has an equally wide range, or even wider range, as it finds its way into commercial industries, so numerous and varied that though we may have given years to the subject, in the same manner as have all metallurgical investigators, our learning is but slight.

Crushing or dividing may possibly be subject to two or three general mechanical principles. Dynamic action due to impact, when the energy forces rend along the lines of least cohesive resistance, or by pressure strains rending through slower separation of the crystals, deforming the mass; or by abrasion and separation from the surface inward. The first can be defined as a blow from a hammer, the second by compression in the jaws of a crusher, but the third is more difficult to define, because of its limited employment owing to its waste of energy, but might be likened to the wearing away of the faces of millstones. Nature in the manufacture of soil from the rocks has employed all three, but evidences would tend to show that in finest division she has been prodigal of her energy, for such fine division has been mainly produced through abrasion, except in the case of the chemical separation in the formation of the many clays. It is with this fine division that we, as metallurgists, are at present interested and how best economically it may be produced. For years the "California" stamp has been the most widely used device for the crushing of ores, and held its position in the first rank because fine grinding, as understood at present, was not a necessity, but with the advance from mechanical separation of the gold and silver content of ores, to that of chemical separation, the necessity for finer and finer grinding in order to liberate the mineral has progressed much faster than the mechanical means to do this fine grinding, so that to-day the stamp is slowly giving way to other applications of crushing energy. We very well remember when in 1895 and 1896 we were shown the first adaptation of the pebble or tube mill, and when told what it would do in the way of fine grinding, there was no hesitancy on our part in declaring that the claims were absurd, but shortly after the small mill was started, we were converted, and became the strongest of advocates of the pebble mill for still further reducing what at that time was considered fine grinding, mainly by stamps and rolls.

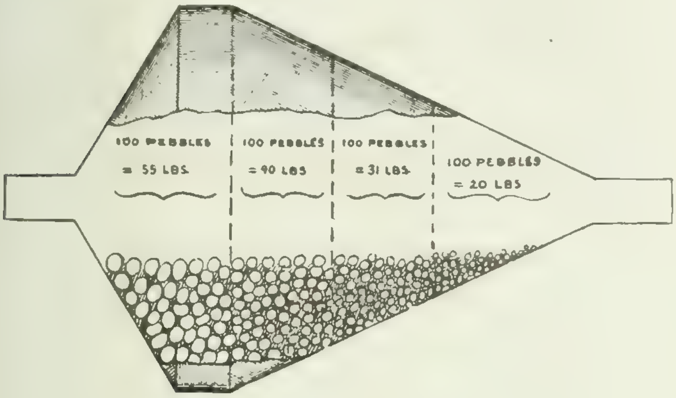


Fig. 1.

In this tube mill was a principal of step reduction not obtained by any mechanical device before that time. The stamp had reached its possible limit because it, with every blow, receded farther and farther from efficiency, owing to increasing disparity of size and weight, between reducer and particle. It has taken a long time to bring us to a recognition of the fact that to economize our energy, the units of force must correspond to the units of matter being acted upon. The well known rule of physics particularly applies here, i.e.: "Crushing strength of a body is in proportion to the area of its section."

We have many times been asked to explain the action within the conical mill, and the cause for its sizing action. Many articles have been written on the theory of the pebble and ball mill, which in turn have produced suggestions and practices resulting in changes of length, diameter, feed, discharge, speed of rotation, charge of pebbles, size of pebbles, etc.

Improvements have been left to the discretion of the machinery designer, who, as a rule, has but little knowledge of the specific technical requirements of the metallurgist, or of where the economic limit begins or ends. We could cite many instances where a lesser expenditure of energy would have improved metallurgical results, and it should be the aim of the metallurgist to fit his machinery to his ore, and not endeavor to adapt his ore to any specific machine. Realizing these conditions, we thought we saw in the conical form of mill a device which could be made more or less adjustable to many classes of ores—from granulation for concentration to sliming for cyanidation, for in the zone of largest diameter, we have all the features necessary for the greatest application of energy, e.g., the largest pebbles or balls, the greatest superincumbent weights, the greatest height of fall and impact due to greatest peripheral speed, and in this zone is found the largest particles of material to be reduced, thus admitting of a much coarser feed than would otherwise be possible if the crushing forces were not segregated. After a first division or reduction, these particles, through the action of the displacement, dependent upon their relative mass, travel up the cone, through constantly decreasing zones of size and weight of crushing bodies as well as decreasing energy due to reduction of peripheral rotation speed proportionate to the division of the particles in passing through successive zones, as illustrated in Fig. 1.

Fig. 2.

In addition to the automatic adjustments of work to mechanical energy, the device is subject to a still further regulation by changing the axis from the horizontal to different inclinations from the horizontal, which will cause the finer particles to travel toward the outlet much more rapidly, and consequently be subject to lesser action of the grinding bodies than when in the horizontal position, which latter position is assumed for the finer grinding. The working machine is provided with means for making these different adjustments.

---

* Abstract of paper presented at Toronto meeting of the Canadian Mining Institute.

For very fine grinding, it is found advisable to elongate the cylindrical portion.

Even the conical mill, subject as it is to varying adjustments, produces vastly different capacity results when working on different ores, as will be seen by comparing the following performance of 8-ft. Hardinge mills operating under similar conditions of power, pebble charge, r.p.m., etc., in three of the largest concentrating plants in the United States, under the supervision of experts of the highest metallurgical order, and though of widely different capacities, as shown, each plant manager reports the results as highly satisfactory.

Fig. 3.

Speed of Pebble Mills.—Authorities vary widely as to the best speed for pebble mills, but in no instance outside of our own product do we find any of these being run above 500 peripheral ft. per minute, but range from 300 to 450 ft., a speed sufficient only for a free movement of the pebbles, while in the conical mill we find the most effective r.p.m. is one which will give 560 ft. at the largest diameter where the greatest work is being done by the largest pebbles on the largest particles, producing a cascading effect, relative to hundreds of small stamps. This maximum of peripheral speed and energy force gradually reduces, in stages or zones, foot by foot until its effective action is fairly commensurate with the work necessary to further divide the previously comminuted particles. Thus in the one machine is a step or stage reduction from kinetic impact to abrasive rolling. The proper and most effective speed is one where centrifugal force is [illegible] they [illegible] by gravity at about 60 deg. from the horizontal. The "proper speed" is much dependent upon the "mesh" of the material fed, for where [illegible] "cascading" action may not be necessary.

In the case of the conical mill the material undergoing division automatically travels forward at each reduction as though actuated by an Archimedes screw up and out the cone, while by the other style of cylindrical mill, of equal dimensions throughout its length, the travel is dependent upon displacement by the feed and the discharge through the same [illegible] of particles from end to end.

Perhaps the most reasons for the sizing and step reduction action can be evidenced by the following diagram (Fig. 3) in which it is shown that when the mill is operated on an inclination from the horizontal the charge is lifted at right angles to the axis, but in falling drops under the action of gravity, vertically and at an angle to the line of lift. The larger particles undergoing disintegration, according to respective mass content, will fall faster than the finer particles which must then, due to displacement, find a position nearer the outlet end of the mill. The material as well as the grinding bodies, through the acceleration due to their mass in falling, reach the lining of mill and continue a course down the cone or inclined surface, toward the larger diameter, forming more or less of a triangular line of travel. The finer particles, according to their size and, therefore, friction surface presented, are retarded in their travel down the cone by surface friction and tend to arrange themselves in zones or classified areas. It is to this zigzag action within the mill that the discharge of material as crushed becomes more or less positive and automatic.

A diagrammatic representation of the actual weights of the same number of pebbles, shovelled from four sections of a conical mill, as reported by an engineer who had just finished a test run for efficiency, is shown in Fig. 3.

In dry grinding the most effective peripheral speed is between 625 and 675 ft. per minute, of largest diameter.

The amount of water used in the conical mill should vary with results desired. For fine or slime grinding the best results are obtained with a relation of about 40 per cent. of water to 60 per cent. of solids, by weight. For coarser or granular grinding greater amounts of water are used to suit conditions and can only be ascertained by experiment.

The following results taken from screen tests covering a period of several days, operating with different amounts of water and inclinations of mill, upon the same (composite) mesh and weight of feed, will give a fair idea of possible results which may be obtained in the one mill:

Mesh	% on 8	% on 20	% on 40	% on 60	% on 80	% on 100	% through 100
Heads	16.7	51.1	13.9	6.8	4.4	3.0	7.0
Tails of 1st test		4.8	9.8	22.8	22.3	0.9	39.0
Tails of 2d test...	......	......	1.3	8.0	27.5	2.5	60.0
Tails of 3d test...				1.4	10.0	2.0	87.0

Lining.—The pebble mills are lined with silex blocks throughout or a combination of silex and ribbed steel or iron plates, the plates being fitted with a lifting bar of special design, which not only assists in lifting the mass of pebbles higher, affording greater impact in the central portion of the mill, but also prevents a slipping of the charge.

The conical ball mill is lined, as are the other types of ball mill, with steel plates, and various sizes of steel balls are employed to break up the ore or other material undergoing disintegration. Herein comes again the principle of the stage reduction, in that the balls in weight are approximately relative to the size of particle undergoing division, and automatically take positions in the mill relative to size and diameter of cone. To operate a ball mill of this type to best advantage, the preliminary feed should be reduced by rock crusher so that the largest pieces will not exceed 1½ to 2 ft., or a relative weight to the crushing body of approximately 50:1.

◆

Survey is being made for an electric line from Port Haney, on the main line of the Canadian Pacific Railway 26 miles east of Vancouver, and also on the Fraser River, to Lillooet Lake. It is presumed that this is being carried on by the British Columbia Electric which has water rights on the river and lake, and which it will develop. This company is rapidly extending its interests on the lower mainland and at Victoria.

THE MONTREAL HARBOR.

The Montreal harbor, as the gateway to Canada, is our most important port. The marine traffic of the port of Montreal comes second only to that of the port of New York among all the ocean ports of North America. The Harbor Commissioners have had in view the necessity for providing adequate facilities for taking care of the traffic flowing through the port. The government has been generous in the past in providing funds for the improvement of the St. Lawrence River channel and for placing the harbor in shape to compete with the ports in the United States. A great portion of the export traffic from Montreal is grain, and it is, therefore, necessary to provide plant for the unloading of the railway cars, capacity for the quick unloading of inland vessels, storage capacity for grain to eliminate the necessity for direct and almost direct transfer of inland cargoes to ocean vessels, and facilities for shipping grain from the elevators. In this issue of *The Canadian Engineer* will be found a description of the new grain elevator at Montreal, which has just been finished, having a total capacity of 2,622,000 bushels. The elevator represents the most modern design and development in this type of construction, and reflects a good deal of credit upon the Harbor Commissioners and the constructing engineers. It will, no doubt, have a thorough trial of its efficiency this coming season, and should do much towards relieving the congestion of last season.

OPERATING RESULTS OF A DOUBLE-DECK STREET CAR.

We noted in the issue of August 29th the introduction of the double-deck street car into the transportation question of some of the larger American cities. Operating results on the Pittsburg double-deck car have been published, and, while these are only preliminary, as the car has been in service only for a month, they throw some interesting light on the ability of this type of car to handle traffic under city conditions without confusion in boarding and alighting, and without the slowing down of schedule speeds. The car is an open trailer, built single-ended for trial use, and the separate entrance and exit doorways are equipped with plain, swinging half-doors. These doors, however, have been re-designed, for a quick-acting door materially cuts down the delay in loading and unloading. The results so far indicate that for handling heavy traffic, where people are loaded at one point and are unloaded within a restricted area, having comparatively few stopping points, the car is undoubtedly a success. This applies especially to the case in which very large crowds have to be moved to or away from ball parks or racetracks, or where large factory forces are leaving their work, so that the entire load is presented at practically the same time.

◆

THE DESIGN OF IRRIGATION WORKS.

In his address to the sixth annual convention of the Western Canada Irrigation Association, Sir William Willcocks laid emphasis, among other things, on the boldness of the design of engineering structures in Western Canada. Sir William Willcocks, in addition to being a noted irrigationist, is the designer of the

Asouan Dam. He states that all the regulating works on the western streams are not so conservatively designed here as in the East. He adds that where the welfare of millions of people is concerned the engineer in the East cannot afford to run any risk; time alone will show whether the boldness of the engineers in Canada is justified or not. His statements are exceedingly interesting and deserve careful attention. It is true that irrigation conditions in Western Canada are very different from the far East. At the same time Sir William sounds a note of warning which should not be disregarded. It is perfectly right and proper to design economically, but where it is a question of safety or economy, safety, of course, must rule. He states truly when he says that the original works can be cheaply built in the dry; once the canal has begun to carry water and establish water duties, works are costly, indeed, and attended with risk.

THE AMERICAN ROAD CONGRESS.

The American Road Congress in Atlantic City this week will bring together everybody interested in the improvement of highways, from national and State officials down to the taxpayer. In fact, this last-named attendant will be particularly welcomed, for his vote decides the question of improvement, and one object of the Congress is to give him information which will enable him to reach a wise decision. The importance of good engineering and good contracting on road improvements will assume large proportions in his mind when the taxpayer learns how essential these factors are to the economical use of the money he furnishes. He does not appreciate this yet, and he is in danger of being misled by enthusiasts whose knowledge is not much greater than his own. At the Congress will gather the experts who have made a scientific study of road-building, the administrative officers in charge of the work, the users of roads who realize the necessity of intelligent improvement and adequate maintenance, and the men who produce the materials and machinery used in road-building. The original plans were developed jointly by the four national organizations representing those who foot the bills, the builders, the users, and the material and machinery manufacturers. Later, the road-builders' organization decided to withdraw. It is unfortunate that all of the organizations in the road congress coalition formed last year could not hold together, and so concentrate their efforts for the good of a cause which is more important than the individual advantage of any organization. However, the gap left by the withdrawal of the road-builders' association was taken by a number of its leading members and other prominent specialists, so that no change in the Congress programme originally announced has been necessary. A feature of the Congress which is likely to be particularly instructive is the exhibition in which the United States government, numerous States and the manufacturers of machinery and materials will co-operate. The details of this display have been worked out so [illegible], and the exhibits are so [illegible] that [illegible] the result will excel anything previously accomplished, even at the Brussels Exposition two years ago. Relatively few people, even among civil engineers, have a true appreciation of the extent of the road-building industry, and this exhibition will, therefore, emphasize the importance of the proceedings of the Congress by demonstrating the magnitude of the interests engaged in highway construction.

THE LAUNCH OF H.M.S. "AUDACIOUS."

One of the most interesting naval events of the year has just taken place at Birkenhead, England, where the new battleship of the super-dreadnought type, H.M.S. "Audacious" was successfully launched by the Countess of Lytton from the yards of the shipbuilding firm of Messrs. Cammell, Laird & Company. It is one of the most powerful ships under construction, and naturally attracted many people from all over the British Isles to witness the ceremony, and it was necessary for a special train to leave London in order to convey some of the 1,100 guests of the company.

Canada was represented by Colonel Sam. Hughes, Minister of Militia and Defence, who the night before had just returned from the French Manoeuvres, and who, the following week, was to be the guest of the King at the military manoeuvres, which this year were carried out near Cambridge.

As is the case at the launch of all units of the Royal navy, a religious service took place, after which Lady Lytton severed the silken cord with an ornamental axe of free rennaissance character, that had been specially designed, and the great vessel glided slowly into its native element.

The event was witnessed by many thousands of spectators, who crowded every vantage point, and thronged the special patforms that had been erected.

The chairman, Mr. W. Hichens, in his speech, made some interesting comparisons. He said:

"The present ship is not the first of that name in the annals of the British navy. So far as I know there have been two others. The first was a wooden frigate of 1,624 tons and 168 feet in length, built during the reign of George III. The second was built in 1869. She was an iron cased vessel of 3,774 tons and 280 feet in length. The present 'Audacious' would hold two comfortably, being 550 feet long and having a displacement of 23,000 tons."

The representative of the Admiralty, Captain H. B. Pellay, M.V.O., R.N., made another interesting comparison when he pointed out that a projectile from one of the 13.5 guns of the "Audacious" was heavier than the whole broadside of H.M.S. "Victory," of 1805.

H.M.S. "Audacious" is of the same type as H.M.S. "King George V.," and the group, when completed of the four vessels, will be the "King George V.," the "Centurion," the "Ajax," and the "Audacious."

The type is an improvement on the battleships of the "Orion" class, although similar in design generally. Whereas the "Orion" and her sisters have a displacement of 22,500 tons, the class to which the "Audacious" belongs displaces slightly over 23,000 tons, and has a length of 555 feet, as compared with 545 feet, with a beam of 89 feet, which is slightly in excess of the 88½ feet of the other class.

The Propelling machinery, as in the case of the Dreadnoughts, consists of Parson's turbines with Yarrow type boilers. There are to be ten 13.5 inch guns mounted in five turrets on the centre line of the ship, while the guns for repelling torpedo attack are twenty 4 inch calibre, that is four more than in the "Orion" class.

It is a notable feature in connection with this vessel that the armour plate is of exceptional thickness and this is already at the dock waiting to be placed in position, now that the launch has been successfully carried out.

Two interesting facts come to light in connection with the firm of Messrs. Cammell, Laird & Company in that they were the owners of the "Sirius," which was the first steamship to cross to New York, and in 1834-5 they built two iron steamers for the Honorable East India Company for the exploration of the River Euphrates.

TESTING NEW CAST-IRON WATER PIPE LINES FOR LEAKAGE.

The methods for testing new cast iron water pipe lines for leakage and the amount of leakage to be expected on good work, was discussed by E. G. Bradbury, of Columbus, Ohio, in a paper read before the Ohio Engineering Society, and published in the proceedings of the Society for 1912. A brief abstract of the paper follows:

A discussion of the methods of testing new lines of cast iron pipe for leakage, and an estimate of the amount of leakage to be expected in well laid lines, was given in a paper by E. G. Bradbury, of Columbus, Ohio, before the Ohio Engineering Society. The paper which is published in full in the Proceedings of the Society for 1912 is here briefly abstracted.

From experience with a number of pipe systems, the writer has become convinced that under ordinary conditions of pipe laying it is improbable that the leakage in a new system will be greatly less than 3,000 gals. per mile daily unless the same is carefully tested and all defects remedied. By testing in the open trench, under a pressure of at least 50 per cent. in excess of the maximum static pressure expected in the pipe, recalking all dripping joints and replacing defective pipe, it is possible to reduce leakage to an extremely low amount.

Reliance cannot be placed on the behavior of the pressure gauge in judging of the tightness of pipe. The gauge may, under certain conditions, drop rapidly when there is no leakage, owing to failure of the gates to close with absolute tightness, or perhaps to air contraction or absorption. It may stand up fairly well to pressure when there is considerable loss, if a large amount of air has become entrapped, and has reached its minimum volume.

Water is reduced by 1/21740 of its volume per atmosphere. Assuming the case of a 6-in. pipe of 1,000 ft. long as representing the average section under test, the volume of water contained is 1,470 gals., if the pipe is completely filled. If this water is under pressure, 1470/21740 or .065 gals. must be lost in order that the pressure may drop 15 lbs. Experiments by the writer indicate that 16,000 drops from metallic surfaces are approximately equal to 1 gal., and on this basis 70 drops would necessarily escape from the pipe referred to for each loss of 1 lb. pressure. With first-class calking, when the men know the work is to be tested in open trench, the average loss from 1,000 ft. of pipe before testing is about 200 drops per minute equivalent to about 90 gals. per mile per day. By going over the joints leakage may be reduced to a point where there is no visible dropping or escape of water, and pressure can then be maintained for a considerable length of time, if the pipe is free from air.

If there is air contained in the pipe, it is often impossible to maintain pressure. This may be due to any or all of the following causes: Air will undoubtedly escape through minute crevices that cannot be penetrated by water. In the compression of air heat is generated, expanding the air, and in the cooling process following, the air necessarily contracts and a loss of pressure results. To what extent this takes place in the comparatively slow process of increasing the pressure in a pipe test, or in other words whether all of the heat is radiated during the process of compression, is not known, but in view of the fact that air compressed to 150 lbs., and not cooled, is increased over 500 deg. F., and has a volume practically double that of the same air under the same pressure after cooling, it is possible that some slight action of this nature may occur. Further, as the pressure is thus reduced, the natural tendency is for the air to lose more of its heat, inducing further contraction. It is also probable that there may be an absorption of the elements of the air by the water. The amount of gas absorbed by water at a given temperature, is a function of the volume, regardless of pressure, and the weight of gas absorbed is therefore proportional to the pressure. Variation of temperature also effects absorption. A very complex action must necessarily result from these conditions, but the general tendency of the several factors is in the direction of reduction in volume of the pipe, with consequent loss of pressure. It is never possible to maintain pressure in a test made immediately after filling the pipe as well as a few hours later. This is undoubtedly partly, and in some cases wholly, due to the absorption of water by the yarn in the joints, but if air is present it often contributes to the trouble.

In reports descriptive of tests of this nature, appear frequent references to the difficulty of obtaining anything like uniform results with the pressure gauge, and the loss of presure often observed where no leakage is apparent is the occasion of considerable surprise. The writer is convinced that if all air is excluded from the pipes and all joints kept visible during the test this phenomenon will disappear. Owing, however, to the difficulty of getting rid of the air this is not always feasible in practice. Excellent results may be obtained, regardless of the behavior of the gauge, if all parts of the pipe are inspected under pressure and all visible leaks stopped. This method also eliminates possible trouble from minute gate leakage.

During the summer of 1911 the attention of the writer was particularly called to the subject of this paper by his connection, as designing and supervising engineer, with the water distributing system of the village of Grandview Heights, Ohio, a suburb of the city of Columbus. An arrangement was made by this village to purchase filtered water from the Columbus water works at a net price of $1.20 per 1,000 cu. ft. The necessity for the tightest possible work was obvious and specifications were drawn requiring that all pipe be tested in the open trench, under a pressure of 150 lbs., to the satisfaction of the engineer. The system comprises 5,719 ft. of 12-in. pipe, 7,701 ft. of 8-in., 16,508 ft. of 6-in. 75 valves, 36 hydrants and 2 air valves. Every section of pipe was tested and gone over until no evidence of leakage was visible with all pipe exposed. The record of tests shows that in many cases gauge pressure could not be held, though every pipe and joint was in plain sight and no leakage could be located.

After completion a number of observations of the water entering the system were made by means of a 1-in. meter. Two service pipes were connected with the system during these tests. The amount passing the meter varied, the minimum being 10 and the average 25 cu. ft. per day. It is perhaps not unreasonable to assume that the minimum metered quantity for one day expresses the leakage from the system, but the average figure was taken. The working pressure on the system varies from 45 to 90 lbs., averaging about 65.

On the completion of the system a 6-in. meter was installed at the Columbus water works pumping station for the measurement of all water sold to the village. This meter was new and was carefully tested by the city department and stated to register accurately down to the smallest stream provided by their testing apparatus, namely 1/32 in. It is, however, probable that there would be some under-registration in case of very small flow. During the first month's operation but two services were connected, and the quantity of water registered by the meter was 600 cu. ft., equal to a little less than 27 gals. per mile per day, including whatever may have been used by the two consumers. Soon after this 80 taps were made. After an interval of about two months the city meter and all individual meters were read. The amount of water passing the 6-in. meter for the period of 58 days was [illegible] cu. ft. and the sum of the readings of the house meters was 39,300 cu. ft. During this period an extension of 550 ft. was made and water was used to settle the trench to the amount of 1.2[illegible] cu. ft., leaving a quantity unaccounted for of 100 cu. ft. or 2.3 gals. per day per mile. The amount of water supplied to the village was equal to 17.5 gals. per consumer per day, figuring on the average number connected for the entire period. The population is suburban, and the use purely domestic. The writer believes that few complete systems have been installed with as low a leakage as this.

The value to this municipality of a tight system is, of course, much greater than to cities pumping their own water, the net cost of water being slightly over $0.16 per 1,000 gals.; for each 1,000 gals. per day per mile lost, the actual cost is about $320 per year, which, capitalized at 4 per cent., amounts to an investment of $8,000, or, in other words, if the system had a leakage of 1,000 gals. per day per mile (which is considerably below the probable average in similar systems), the village could afford to spend $8,000 if, by so doing, the leakage could be reduced to the present amount.

The value of tight water pipes to a city pumping its own supply is less readily computed. Fixed charges, attendance, etc., are not materially affected by moderate leakage, except as additional capacity is required at an earlier date. The fuel bill, and, in case of treated water, some items of the cost of purification, are chargeable in proper proportion to such leakage as may exist. It may safely be stated that the cost of careful inspection and testing is always more than justified by the saving that can be accomplished.

Regarding the amount of leakage permissible in new work, general practice would appear to justify anywhere from 60 to 250 gals. per day per mile per inch of diameter. Loweth proposes 60 to 80 gals. per inch-mile. Gregory, in the improvements to the Columbus water supply, specifies the limits of allowable leakage, under about 110 lbs. pressure, given in Table I.

Table I.

Size in.	Leakage allowable, gals. per hour per lin. ft	Equivalent in gals. per 24 hours per mile	Gals. per 24 hours per inch mile
20	0.08	10,138	507
24	0.10	12,672	528
36	0.15	19,008	528

These requirements would seem to lean far toward liberality. The writer is of opinion that except under particularly unfavorable conditions, it is possible to reduce the loss to a very low figure—so low indeed as to be almost negligible. Open trench testing, as above described, and rigid insistence on the closing of all visible leaks will accomplish this result, and by no other means can it be done. It is better to specify this test than to state figures of permissible leakage, as results far better than one would feel justified in specifying are possible, and it is impossible to demand better work than required by the specifications.

RAILROAD RATES

"The only just method of determining the reasonableness of transportation charges is to measure them by the service performed." That was a recent statement of Mr. W. W. Finney, president of the Southern Railway Company. "This is all right as far as it goes," replied a newspaper editorial, "but will not Mr. Finney tell us how to apply this yardstick?" Subsequently, the railroad president did so, and in response to a request, he has forwarded his views on the matter

At the outset, he says, it should be borne in mind that the railways of the United States—although public highways, and, as such, properly subject to such governmental regulation as will insure to all citizens equality of rights on them, under similar circumstances and conditions, and as will prevent unreasonable or extortionate charges—have, nevertheless, been built with private capital and are the private property of their owners.

It is a fundamental economic truth that the investment of funds in any class of property is dependent on the safety of the principal and the rate of profit that may be expected as compared with the rate that can be earned on investments in other kinds of business. In other words, the flow of capital into any particular business will be retarded unless it may be expected to earn a reasonable profit as compared with the earnings of capital in other enterprises.

The question of what is a reasonable charge for a specific service is complicated by the fact that neither as a matter of transportation policy or of public policy can charges on all classes of traffic be uniform. Commodities of great weight or bulk in proportion to their value must be carried at rates substantially lower than those which may properly be charged for the carriage of commodities which are of high value in proportion to their weight or bulk.

As a result of the necessity for different rates on different classes of commodities, each individual rate or each rate applying to a class of commodities must be considered on its merits in its relation to the particular service performed. The cost of performing the service, as nearly as it can be ascertained, must certainly be taken into consideration. No rate should be made so low as not to pay something more than what Mr. Acworth, the eminent English economist, has aptly termed "the actual out-of-pocket cost" of moving that particular traffic. If it pays this cost and contributes, even in a small measure, toward the general expenses and fixed charges of the carrier, it is a profitable rate, provided the carrier has a considerable volume of traffic moving at higher rates. The low-class traffic moved at these low rates is not a burden on the higher-class traffic, for, by just so much as it contributes to general expenses and fixed charges, it reduces the amount which the higher-class traffic must contribute. In practical rate-making the question of the cost of the service has a controlling bearing only as determining the level below which a rate can not properly be made.

The value of the service is another important factor in rate-making and in determining the reasonableness of a rate that may be challenged. Transportation enables those engaged in any given industry to carry on their business in those localities best suited for it and to market elsewhere the surplus not needed for consumption at the point of production. By moving commodities from places where the supply exceeds the local demand to places where they are scarce and are wanted additional value is given to the whole volume of production, including the proportion consumed locally, as well as to that carried to other markets. As affecting the consumer of, let us say, cotton goods, by way of illustration

—the carriage of the raw cotton to the mill and the transportation of the finished goods to his market, is a process of production. This transportation gives added value to the raw cotton produced on the farm and to the goods procured in the cotton mill, and the carrier is, therefore, entitled to fair recognition for its service in the process of producing the finished cloth and placing it in the hands of consumers, just the same as is the farmer and the cotton mill owner.

The increased value given to a commodity by transportion is the measure of the value of the service to the owner of the commodity. It is not, however, the absolute measure of a reasonable rate, for, if the transportation charges were so high as to absorb all of this increased value, the owner would have no incentive to ship and the traffic would not move. This may be illustrated by referring to the rail movement of a very low-grade commodity, such as ordinary sand —a commodity which is found in abundance in most localities and the value of which, generally speaking, can be very little increased by transportation. It is manifest that it would be impossible to make a practical rate on sand for any such distance as from Philadelphia to Chicago, for the reason that the out-of-pocket cost of performing the service would be far in excess of the value of the service to the shipper.

As transportation has contributed all of the increased value which is given a commodity by its carriage to market, which, as we have seen, is a factor in effective production, the carrier is entitled to a reasonable share of that increase. The value of the service is, therefore, a most important factor in determining what is a reasonable charge for a specific transaction. Out of the intimate relation of the cost of the service and the value of the service to the reasonableness of a transportation charge grows the fact that, in an era of generally advancing prices, when both the cost of the service and the value of the service are increasing, the level of the reasonable charge for the service thus affected also advances.

In determining the proportion of the value of the service which the carrier may reasonably and justly charge for its part in creating that value, intelligent consideration must be given to comparison with rates charged by the carrier for other similar services, to comparison with the rates of competing carriers, to comparison with the rates at which carriers in other localities move the same commodity under similar circumstances and conditions, to comparison with the rates on similar commodities which might be substituted in use for the one in question, to the intrinsic value of the commodity, to the risk of breakage or other injury in transit, to the insurance risk, to the effect of the rate on the volume of traffic, and to the general condition of the business to which the special traffic is related. When the reasonableness of a rate is called into question, consideration and great weight must be given to expert testimony.

Of all these guides for determining the reasonableness of a specific rate, the effect on traffic is perhaps the most important, for an increasing volume of traffic is prima facie. and almost conclusive, evidence that the rate is not unreasonably high, though it may be unreasonably low.

It will be seen that, in the final analysis, the reasonableness of a transportation charge is largely a matter of expert judgment. So is the reasonableness of any price or charge that may be called into question. If one of you employs a lawyer, without any agreement as to what his fee shall be, and, after the service has been performed, you decline to pay his bill on the ground that it is too high, he sues you for the amount of his bill. The question raised is what would constitute a reasonable charge for the service performed. and, on this, testimony will be introduced to show, primarily and principally, the value of the service to you. Testimony will also be presented as to the usual fees which this lawyer and other lawyers receive for similar services, as to the amount of time consumed, and the skill which he displayed in rendering the service. Based on this testimony the jury will form a judgment as to what is a reasonable charge for the specific service performed.

The same method is followed in condemnation proceedings when a railway company seeks to acquire land for railway purposes and fails to reach an agreement with the owner as to the price to be paid. The question here presented is as to the fair and reasonable present value of the land to its owner and as to the fair and reasonable amount to be allowed him for the damage, if any, that may result to his remaining property by the construction of a railway through it. Evidence will be considered as to the value of that particular strip of land, as to the profitableness of the uses to which it has been put by its owner or of the uses to which it might be put. Evidence will also be considered as to the prices at which other tracts of land in the same locality have been sold, and on all these points expert testimony will be considered. The amount which the owner paid for the land, if bought sufficiently near the time of condemnation to be pertinent, may be introduced in evidence and will be considered, but it is not controlling on the jury, which, from all the evidence introduced, must determine what is the just and reasonable compensation to its owner at the particular time when it is taken.

◆

RAILROAD EARNINGS.

The following are the railroad earnings for the week ended September 7th:—

	1911.	1912.	Increase or decrease.
C.P.R.	$2,230,000	$2,649,000	+ $419,000
G.T.R.	1,033,652	1,082,457	+ 48,805
C.N.R.	336,500	376,400	+ 39,900
T. & N.O.R.	39,787	29,610	— 10,177
Halifax Electric	8,553	5,627	— 2,925

The Canadian Northern Railway earnings and expenses for August with comparisons were as follows:—

	August. 1912.	August. 1911.	Increase.
Gross earnings	$1,745,800	$1,420,600	$325,200
Expenses	1,375,000	1,105,900	269,100
Net earnings	370,800	314,700	56,100
Mileage in operation	4,297	3,711	586

For the months of July and August net earnings of the road increased $189,100 over the same two months of 1911.

From July 1st to date gross earnings were $4,720,400, an increase of $753,500.

The net earnings of the Toronto and Northero Ontario Railway from the beginning of the financial year, November 1st, to the end of June, as reported to the provincial treasurer, have been $350,022, as against $314,814 for the same period last year. The gross receipts have been $1,178,839 against $1,024,382 for the same months of last year. The net earnings include or royalties of $98,436 this year, compared with $18,391 from the same source last year.

The increase in mileage for the period of nine months has been 264.24. The mileage increase last year in the same period was 174.28. The ore royalties for June this year were $26,427, while a year ago in the same month the ore royalties were nothing.

INSURING SOUNDNESS IN STEEL RAILS.*

By Robert W. Hunt.

While steel rails have been of great scientific and engineering interest from the day of their first experimental use, and much literature has been written upon them, there has never been a time, at least in America, when matters relating to their manufacture and service have received as much public and even governmental attention as during the past two years. I have been actively identified with the manufacture of steel rails from the rolling of the first commercial order for them in America up to and including the present time. As a steel maker I became thoroughly familiar with the theoretical and practical details of the business; and later, as a consulting engineer and inspector of all steel products, and especially of steel rails, I have endeavored to keep in touch with and cognizant of everything relating to the art.

All steel rails are made from steel ingots. Steel ingots are formed by pouring or casting liquid steel into cast iron ingot molds. The larger the cross section and the greater the length of the ingots, the greater the difficulty in obtaining sound castings, i.e., sound and homogeneous ingots. Without sound and homogeneous ingots it is impossible to produce sound and homogeneous rails; and, unfortunately, the most important unsoundness will be first in the centre of the ingot, and last in the centre of the rails produced from it, where it is frequently impossible to detect without destroying the rails. The large tonnage in each heat of rail steel (whether made in Bessemer converters or in open-hearth furnaces) under present mill practice, necessitates the casting of ingots of large cross-section and long enough to make several rails.

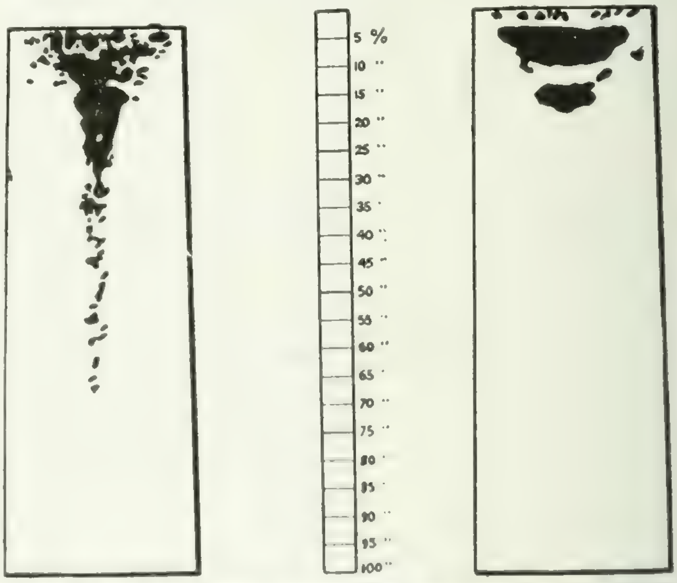
It is a long-known fact that the greater the mass of steel in a casting, the greater the tendency of the metalloids (carbon, phosphorus, sulphur and silicon, and particularly the hardening metalloids, phosphorus and carbon) to segregate at the part of the casting where the metal remains longest liquid, which, under normal conditions, is at the centre and toward the top of the mass. Again, it has long been known that the necessary cooling of the metal from the outside inward causes a contraction which results in the formation of a cavity or "pipe," which defect is increased by hasty and uncontrolled casting of the molten steel into ingot molds. Over twenty years ago Robert Forsyth, then chief engineer and manager of the Union Steel Company, Chicago, Ill., demonstrated that if rail-steel ingots were laid on their sides before the interior steel had set, the pipe would not be formed in the middle of the top end of the ingot, but upon the upper side and liable to extend toward the bottom end; and that, therefore, ingots should be left standing in a vertical position [illegible] (Journal of the Franklin Institute, Vol. 127, May, 1889).

Many times, labor and money have been expended in seeking to overcome the piping and segregation in ingots without greatly increasing the cost of production through expense of operation, lessening product, etc. Technically [illegible] all, more time. Unfortunately for success in casting sound [illegible] Therefore, the soundness of the resulting ingots is a matter entirely independent of the personal skill of the workmen. However, while the efforts to produce sound ingots have not been generally commercially successful, I am loath to believe that the difficulties will never be overcome. Such has not been the spirit under which the great successes of the past were accomplished, and I do not think it now exists. If a positive necessity for sound ingots be commercially established, a commercial way to produce them will be found.

As the general existing conditions produce ingots with the most undesirable steel in their upper part, it has been and is the practice in manufacturing steel locomotive tires, ordnance forgings, armor plate, large steel shaftings and other what are termed high-grade products, to reject arbitrarily at least the upper one-third of the ingot. It is true that even so great a discard will not always prove an absolute safeguard, but if the ingots are carefully made it will do so. Against bad or ignorant workmanship it is hard to find any absolute protection.

In rail purchases it has been found impractical to secure so great a discard. Personally, I believe the future will bring it, unless the insistence upon it shall lead to improved methods in casting ingots; until that time comes, I think that, through the railmakers developing other uses for the discarded steel, the decided increase of cost will be avoided.

Experience has proved that rails made by the basic open-hearth process are more liable to have interior pipes and segregated spots than Bessemer rails; no doubt principally because the ingots are larger and the size of the heats prevents slow casting. Of course the smaller contained percentage of phosphorus lessens the danger from its segregation, but the greater carbon content made possible by the law phosphorus increases the segregation of that element.



Figs. 1 and 2. Cross-Section of Ingots from the Same Heat Showing Different Depths of Piping.

Intelligent and careful investigation by a committee of the American Society of Civil Engineers, of which I had the honor of being secretary, resulted, August 3, 1893, in the recommendation of a series of rail sections which, while not adopted by all American railways, were used by so great a number that they became accepted as standard sections. In [illegible] another committee was appointed by the same society, of which also I was secretary. That committee, while deciding not to recommend any change in rail sections, did present certain specifications governing the manufacture of rails. Later developments resulted in that committee asking to be discharged in favor of one more directly representing the railway organizations of the country; and this committee (American Railway Association committee) recommended, under date of March 23, 1908, a series of rail sections which have, to a certain extent, displaced the so-called American Society sections; and, in my judgment, wisely so. The same committee has recommended rail specifications; several railway companies have adopted their own, and the rail manufacturers have what are known as Standard Specifications, all seeking to secure good-wearing and safe rails. All of this has been accompanied by much discussion, and I know has resulted in much good; but we are still away from the desired certainty of safety.

I believe we can afford to let the chemical requirements remain as they are in most of the specifications. Their physical requirements as to finishing temperature also are sufficient, and most of them provide for sufficient drop-testing so far as determining the quality of the steel of the several heats as metal; but they do not go far enough to give protection against unsound castings (i.e., ingots). Practically all specifications require that the test piece shall be taken from the upper end of the rail made from the top of the ingot; and several require that after drop-testing if the piece has not broken it shall be nicked and broken to expose the interior, and if the interior of the rail shows any defects all of the A or top rails of the heat shall be rejected.

So far, so good. But each ingot is an individual or separate casting; and because one is sound, it does not prove that the others (say 4 in Bessemer or 29 in open-hearth practice) are also good castings. As showing what does happen, I give diagrams (Figs. 1 and 2) of two ingots which were cut longitudinally through their centres. With such variation as here shown, it follows that the test piece from one ingot would not be representative of the other one. Therefore, I favor drop-testing as now, and nicking and breaking those test pieces, and also a piece from the rails made from the upper end of each and every one of the other ingots, and accept the seemingly sound and reject the proven unsound A rails. And I would go further and provide that, where unsoundness is shown, another test piece shall be cut from the lower end of the represented A rail and nicked and broken. If it also shows unsoundness, then the B rail of that ingot shall also be rejected, and another piece cut from the lower end of that B rail, and, if unsound, the C rails condemned; and so on for the remainder, if any, of the ingot. This makes a practical way of determining how far the pipe or segregation has extended down the ingot, with the minimum destruction of merchantable rail. Such a plan of testing is not entirely new in principle, and was in part suggested by the late William Metcalf in 1908, when he was consulted by the Rail Committee of the American Railway Association. The additional test pieces can be taken from the rail ends which are made in hot-sawing the rails, and can be broken under much less cumbersome tools than the drop testing machine and at small cost.

As to what constitutes interior defects, I unhesitatingly specify not only laps or pipes, but also silvery or bright spots, or other indications of non-uniformity. Etchings and analyses of a great many examples of the latter have proved them to unfailingly indicate segregation. I give in Figs. 3 to 8 views of the sections of nickel and broken rails, and of the same pieces after having been polished and etched; also analyses of drillings taken from the indicated positions. Table I. shows the results of other analyses of such spots. These tell their own story.

Rails with segregated centres do not always fail under the drops test, nor does the elongation test which is required by some specifications indicate their existence, but, unfortunately, it has been demonstrated that rails with such hard centres fail through the softer surrounding metal breaking down and thus producing split heads and often broken rails.

[illegible] commercially made, the safest procedure is to arbitrarily reject [illegible] Undoubtedly this harder steel would also yield good results [illegible] furnish a place for the use of a large part of the steel contained in the greater discard in the rail practice. Obviously its use would revolutionize the splice plate and tie plate making, but there have been many metallurgical revolutions and all of them have tended toward the betterment of the iron and steel industry.

It may be that present and future railway practice will require rails of heavier and otherwise different sections from the present ones, but we can never escape from the necessity of having them physically sound. As the section is increased, so must the work of rolling it decrease, and thereby the evil effects of want of homogeneity and unsoundness be augmented.

Plans for a tunnel under the city of Vancouver, beginning at the foot of Burrard Street on Burrard Inlet and running to the False Creek yards are being drawn by the Canadian Pacific Railway preparatory to their being presented to the railway commission for approval. This tunnel has been mentioned several times in conferences between the Canadian Pacific Railway and the city. It is being considered as a means of doing away with the present street crossings in the middle of Vancouver.

◆

Early development of the coal resources of Central Alberta is expected. Mr. Andrew Laidlaw, of Spokane, and associates interested in the Jasper Park Collieries, have just returned from an inspection of their property. Over two hundred men are employed on the property, the entire output being taken by the Grand Trunk Pacific Railway for use on its locomotives. Mr. Laidlaw states that on completion of the installation of additional equipment at least five hundred men will be employed, and the output will be two thousand tons daily.

◆

The Canadian Talc and Silica Company, which owns a talc mine and mill at Eldorado, has purchased a property just east of the village of Madoc, Ont., owned by Mr. J. H. Curley, and known as the Conley property. The president of the company is Mr. H. Hungerford, of Chicago. The intentions of the company regarding the newly-acquired deposit are not made known, but it is supposed that another mill will be erected in Madoc, and ground talc shipped from there.

THE PLANT OF THE NORTON COMPANY AT CHIPPAWA, ONTARIO.

A very interesting plant for the manufacture of silicon-carbide was recently erected at Chippawa, Ontario, and has now been in operation about a year. Mr. Francis A. J. Fitzgerald has written an article which was published in Metallurgical and Chemical Engineering, describing this plant. We herewith present the description slightly re-arranged. We are indebted to Mr. Fitzgerald for the illustrations furnished.

In many ways the manufacture of silicon carbide is unique, the reason being that the properties of the substance itself are peculiar. If a piece of silicon carbide, consisting of an agglomeration of crystals just as they come from the furnace, is submitted to a sufficiently high temperature in an oxidizing atmosphere slow oxidation occurs, the silicon forming silica and the carbon burning to carbon monoxide gas. This may readily be shown by means of an oxy-hydrogen blow-pipe flame. If the flame is turned on the crystals for a short time and these are then examined they will be seen to be covered with minute globules of silica produced by the oxidation of the silicon carbide.

On the other hand, if the crystals of silicon carbide are heated to a sufficiently high temperature in a reducing or neutral atmosphere decomposition occurs without fusion, the silicon vaporizes and the carbon remains behind preserving the original form of the silicon carbide crystals. There is no evidence of fusion. Such an experiment may be performed in a carbon tube, which, of course, is heated electrically.

It is this peculiar property of silicon carbide which makes the conditions of manufacture unique and has thus led to the development of a furnace which to many appears at first sight rather a crude and inefficient apparatus. In most processes for the manufacture of carbides or other compounds which involve the reduction of an oxide, the resulting product is fusible and this simplifies in many ways the manufacturing process as compared with that of silicon carbide where the resulting product is infusible. In the production of a fusible material a moderately careful mixture of the reacting raw materials is satisfactory since slight inequalities or lack of homogeneity in the mixture will not cause trouble provided the proportions of the constituents are correct. The conditions of silicon carbide manufacture, however, are different.

The mixture used in the production of silicon carbide should contain theoretically 60 parts of pure silica sand and 36 parts of pure carbon. When these are thoroughly mixed and heated to a sufficiently high temperature a portion of the carbon combines with the oxygen of the silica forming carbon monoxide gas, and the silicon thus set free combines with the remainder of the carbon to form silicon carbide. During this process, however, the mixture as a whole is not fused. Certainly the sand fuses, but the volume of carbon mixed with the sand is sufficiently great to prevent the particles of silica from running together, but instead of that they react with the carbon in their neighborhood to form, first of all, a greenish-colored substance which shows no crystalline structure, and as the temperature is carried higher this is converted into the crystalline silicon carbide. There is naturally a considerable shrinkage of the mixture, for from a theoretical charge weighing 96 kg. only 40 kg. of silicon carbide are obtained, the remaining 56 kg. disappearing as carbon monoxide gas. The mixture then shrinks, but preserves generally its original form. If the heating is continued so that the temperature is raised still further the silicon carbide is decomposed, as already described, but still there is no fusion and ultimately the carbon which was in combination with the silicon is obtained as graphite.

If a mixture containing an excess of silica is heated a reaction occurs between the silica and the silicon carbide which results in the production of silicon, and this is just what happens in those parts of a silicon carbide furnace charge where there is an excess of silica, due to lack of homogeneity in the mixture.

A consideration of these facts leads to the conclusion that it would be difficult to manufacture silicon carbide in a furnace different in general principles from the well-known form that has been used for the purpose during the past 20 years. Moreover, it is not difficult to understand that the manufacture is one requiring very considerable care in order to obtain a satisfactory product and at the same time to get as large an output as possible.

In the design of the Norton Company's plant for the manufacture of "crystolon," the name given to its silicon carbide, the first consideration was the quality of product, the efficiency of the furnaces, by which is meant the output per kw.-hour, the labor cost and the cost of raw materials being deemed secondary matters. This must be remembered in considering the plant in order to appreciate it fairly.

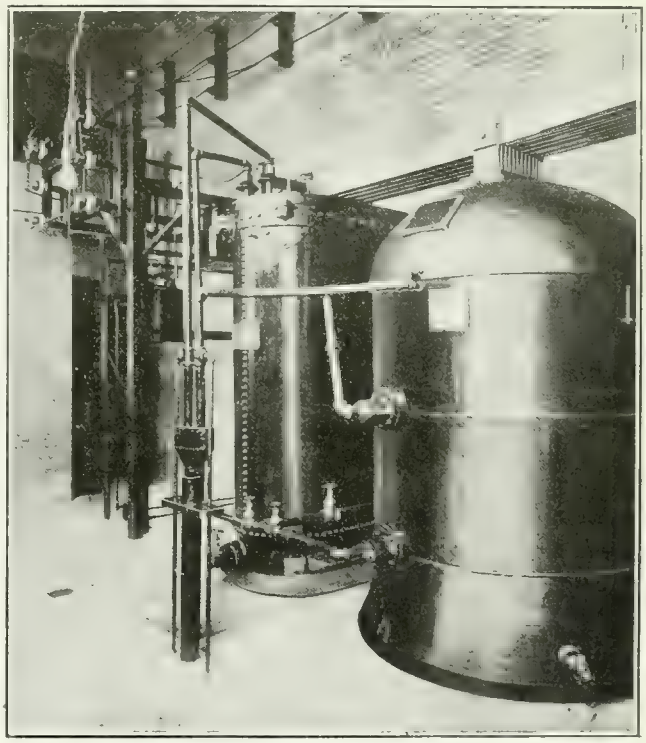

Fig. 1.—Arrangement of Electrical Apparatus in Crystolon Plant of Norton Company.

The Norton Company's crystolon plant is in Chippawa, Ont., about two miles above the Falls of Niagara. The current is supplied by the Ontario Power Company at 12,000 volts, three-phase. Since it was decided to use furnaces having a capacity of 740 kw. and to install only two units, it was necessary to use transformers with suitable taps for the Scott connection so that the three-phase current is transformed to two-phase. The transformers step down the voltage to 145. The secondary bus-bars then go to induction regulators by means of which the e.m.f. at the furnaces may be raised to 215 volts or lowered to 75 volts.

The arrangement of the electrical apparatus is shown in part in Fig. 1. The current enters the building in a room next the transformer room where it goes to the main circuit breaker and where the lightning arresters are set up. The cables from the main circuit breaker are then brought into the transformer room on brackets near the ceiling, as shown in the figure. A frame work, shown at the left, carries two single-pole double-throw switches so that the transformer, seen in the centre, can be connected to any one of the three-phases. The frame work also carries circuit breakers, of which one is connected in parallel with a water rheostat and can be tripped by hand, while the other is provided with an automatic tripping device. The reason for using the water rheostat is that it is frequently necessary to throw the current on at full load and this might cause dangerous surging if the circuit was closed by means of the oil circuit breaker.

To the right of the transformer in the figure is the induction regulator by means of which the voltage of the current is raised or lowered. The induction regulator is built like an induction motor and the secondary voltage varies with the position of the rotor. Its great advantage lies in the fact that there are no contacts as in other kinds of voltage regulators and the change of voltage is perfectly continuous. The disadvantage is that on account of the air gaps between the primary and secondary there is considerable magnetic leakage, and, consequently, the power factor of the circuit is apt to be low. This, however, is more than compensated for by the advantages which make a breakdown of the voltage highly controllable.

The busbars coming from the transformer and regulator are mounted and pass through the wall of the transformer room to the furnace room, which they travel transversely. On either side of the busbar line are three furnaces, these forming one unit, Fig. 2. Between the terminals of each pair of furnaces on opposite sides of the busbar line bars are arranged alike, those on one polarity going down into a concrete trough which passes under the foundations of the furnaces, the other bars terminating on a level with the furnace terminals. The bars going into the trough come out at the other ends of the furnaces and are then connected by means of cables to the terminals, as shown in Fig. 2.

The grounded side of the furnaces, that is, the terminals connected to the busbars through the trough are kept permanently connected, but the other terminal is only connected to the busbars when the furnace is running. In starting a furnace the resistance is adjusted so as to have the maximum voltage at the furnace terminals and this brings the furnace to full load in a few minutes. The resistance still keeps dropping rapidly as the temperature rises, but by means of the regulator the rate of generation of energy is kept constant. Finally the resistance becomes very nearly constant and there is only a gradual fall to the end of the run. Although it is possible to decrease the e.m.f. at the terminals to 75 volts it is customary so to construct the furnace that the resistance at the end of the run requires an e.m.f. of about 80 volts.

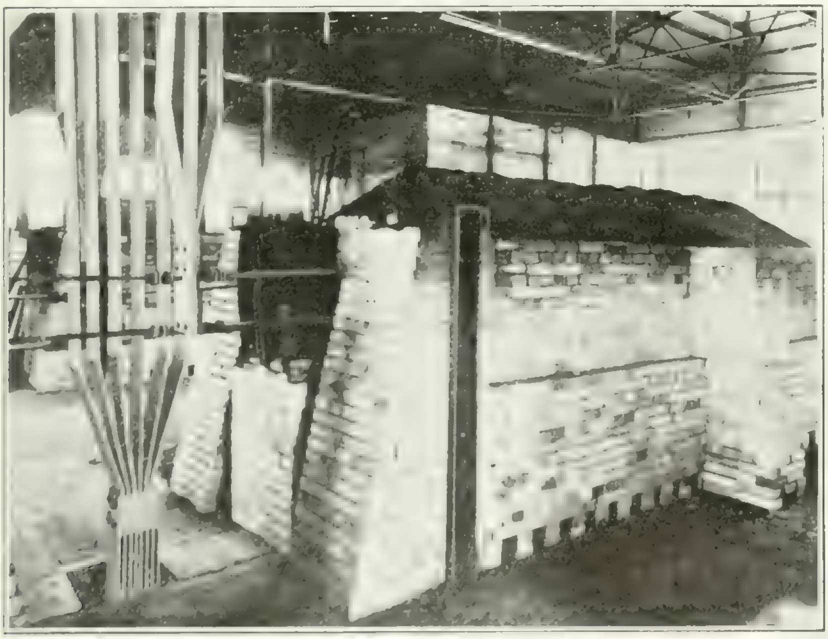

Fig. 2.—Electric Furnaces for Manufacturing Crystolon.

It has been pointed out that an objection to the use of an induction regulator is its influence on the power factor of the circuit. It is found, however, that even with the large current of 9,000 amp. used at the end of the run the power factor is about 0.9.

The raw materials for the manufacture are brought in on a switch at the side of the building opposite to the transformer room. The sand and sawdust are taken from the cars and conveyed to large concrete storage bins by means of elevators. The coke is thrown directly into a crusher, and when the granular carbon for making the resistor used in the furnace is required the coke coming from the crusher is passed over screens which separate particles of the required size. The under size and over size particles of coke are carried to a buhr mill where they are finally ground and thence conveyed to a concrete storage bin.

In making the charge for the furnace a mechanical mixer is used and the mixture is emptied at once into the hand cars which convey it to the furnaces. These are built in the usual way with the mixture surrounding the granular coke resistor. The furnaces have an electrical capacity of about 700 kw.

This question is sometimes asked: "Would not larger furnaces result in more economical working?" It is a fact that the consumption of energy in a small silicon carbide furnace, say of 75 kw., is very large, about 10 kw.-hours per pound, and that in going to a larger sized furnace, for example 200 kw., the reduction in energy consumption is very marked. Again, increasing the size of the furnace to 700 or 800 kw. makes the working still more economical, but about here a point is reached where still further increase in size is of doubtful advantage. This is easily explained when certain of the peculiarities of silicon carbide are considered.

It has already been pointed out that the substance is infusible and that it must be formed between certain temperature limits. The result of this is that when a charge has been partially converted into silicon carbide, the heating resistor is surrounded with a cylinder of the carbide and consequently, the heat which is supplied to the charge must be conducted through this cylinder to the surrounding mixture. It is obvious that there is a limit to the thickness through which it is economical to transmit heat and that very large furnaces would demand such a great increase in the thickness of the silicon carbide cylinder that they would not be practicable. On the other hand, if the thickness of the silicon carbide cylinder is kept the same and the length of the furnace increased so as to accommodate the increased rate of generation, there is nothing gained in heat economy, since the radiating surface of the furnace is increased in proportion to the rate of generation of energy.

Another objection to very large furnaces is the increased difficulty in building with the care necessary to obtain a product of the highest quality possible. Lack of uniformity in the charge or irregularities in the resistor all tend to bring about the production of an inferior abrasive. It is for this reason that the most elaborate care is taken in the mixing of the charge and the construction of the furnaces at the "Crystolon" plant. Analyses of all the raw materials are made as soon as these are received at the plant, then in the Chippawa factory analyses of the raw materials are made twice a day and the mixture adjusted accordingly.

The equipment of the plant is very complete both as regards apparatus and personnel for carrying on research work on the working of the furnaces and methods of manufacture. This research not only covers chemical and electrical studies but also important thermal experiments. Some of the results of this work have been published by Saunders in an interesting paper read at the last meeting of American Electrochemical Society[1] in Boston.

The temperature measurements of the crystolon furnace are of great interest in many ways. They show what exaggerated notions of the temperature of the furnace have been formerly entertained and also the comparatively small range of temperature which can be utilized in making silicon carbide. As determined by Saunders the temperature at which silicon carbide crystals begin to form is only 400 degrees below that of decomposition. There is no doubt that for some processes 400 deg. would be a large range of temperature, but for a substance like silicon carbide, on account of its other peculiarities, outlined before in this article, it is not.

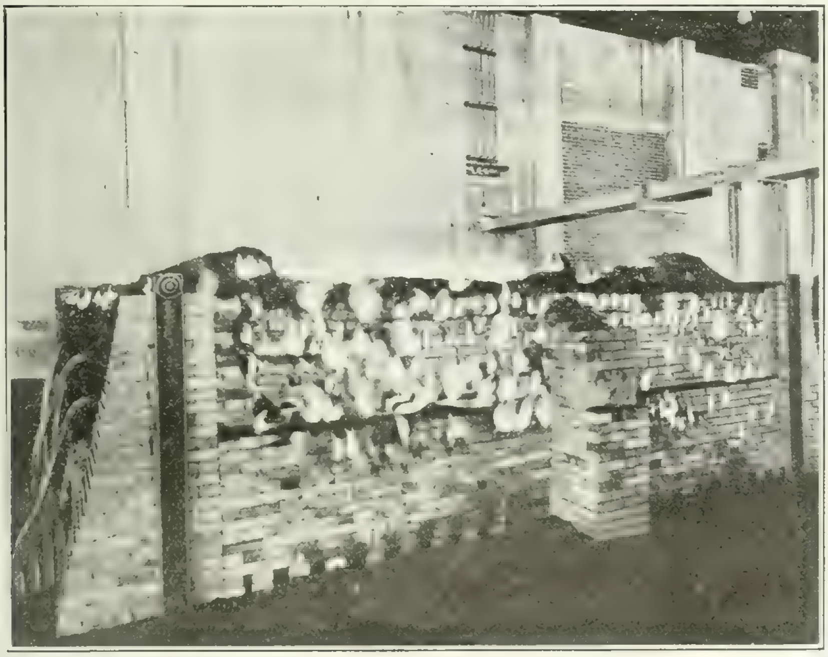

Fig. 3.—Electric Furnace for Manufacturing Crystolon.

The Norton Company's crystolon plant is used simply for the manufacture of silicon carbide, the material as it comes from the furnace being shipped to Worcester, where the crushing, grading and further manufacture is carried on. At first sight it might appear that the separation of the plant where the crude abrasive is manufactured from that in which it is made up into marketable form is not efficient, but experience seems to show that this view is not correct. The separating by no means interferes with active cooperation and at the same time permits of undivided attention to the production of a raw material of the highest quality without which the manufacture of a satisfactory finished article is possible.

THE METHODS OF RESEARCH.*

By Edward P. Hyde.

The spirit of research now prevails. Research work is undertaken in our universities and colleges, both by faculty and by students; research departments are considered most important adjuncts to large progressive industrial organizations; research laboratories are being endowed by philanthropic citizens; and individuals everywhere, and in all branches of human knowledge are independently undertaking the investigation of problems of supposed practical importance or of personal interest. Inasmuch as effectual practice rests on the judicious application of established knowledge, whatever conduces to the enlargement or enrichment of our body of established knowledge is worthy of our highest respect and our most serious consideration. But side by side with this duty of encouragement and appreciation stands that other duty of careful discrimination between the research work that is thorough and genuine and the research work that is ill-advised and spurious.

Not long since the president and council of this society appointed a research committee to stimulate interest in the investigation of important illumination problems, to encourage sane and promising research, and to serve as a directive force in the development of the science of illumination. And it has seemed advisable to the papers committee of the society that a brief paper on "The Methods of Research" should be presented at this convention.

What is research? Knowledge comes to us at times unsought and unexpected. Discoveries are frequently fortuitous. But by research is meant the diligent, continued or laborious search after facts or principles. And the goal of research is truth. This is a most important point. Whatever may be the ulterior motive in the acquisition of truth, whether it is truth for truth's sake, as in the ideal of pure science, or truth as a firm foundation for judicious practice, as in the ideal of applied science, the immediate goal in all research work worthy of the name is truth. The methods of research must, therefore, be included in the methods involved in arriving at truth, and so we turn our attention for a while to a consideration of the methods by which we arrive at truth. Truths must be distinguished in two classes: (1) those truths which are known directly or of themselves, as our own bodily sensations and mental feelings; and (2) those truths which are known through the medium of other truths, as the theorems of mathematics. The former are the subject of intuition or consciousness; the latter, of inference. It is not the place here to discuss the metaphysical question of the dividing-line between truths which are known directly and those which are known by inference. Suffice it to say that practically all, if not quite all, of the truths of physical science are known through the medium of other truths and are hence the subject of inference.

What then are the methods of arriving at truth through inference? The logicians distinguish two methods, that of induction and that of deduction. Let us consider briefly first the inductive method. By induction is meant the process of drawing a general conclusion from particular cases. Thus the law of conservation of energy and the law of universal gravitation are great generalizations which cannot be proved, in the ordinary sense in which we speak of proving a mathematical theorem. They are expressions of our belief in the invariability of certain phenomena which have been found uniformly in a very large number of concrete cases. Many of us believe that so-called glare is deleterious to eye-sight. We have inferred this from observations of individual concrete cases. If true, it is an important truth in illumination arrived at by the method of induction. The exact verity of it, and the limits within which it applies, however, have not yet been definitely established.

---

*A paper read at the sixth annual convention of the Illuminating Engineering Society, Niagara Falls, Ont., September 16-19, 1912.

This last illustration suggests the two processes by which we arrive at truth by the inductive method. These two processes are observation and experiment. By observation, as used here, is meant the passive observation of phenomena without effort to control or modify the phenomena in any way. According to the above illustration, if we merely note that certain individuals have been exposed to strong glaring light and have subsequently had eye-troubles, and infer from this the generalization that glare is deleterious to eye-sight, we are making use solely of the process of observation in our induction. If on the other hand we are not content with the results of passive observation of cases as they occur, but seek rather to control to some extent the phenomena by isolating certain factors and eliminating others, our process becomes that of experiment. Certain phenomena are not subject to control and may only be studied by the process of observation. Other phenomena lend themselves readily to experiment. It should be remembered, however, that each process has certain advantages and disadvantages even in the case of phenomena to which both processes may be applied. Thus the process of experiment is peculiarly valuable in cases where we desire to determine the various effects of a given cause, and the process of observation has corresponding advantages in cases where we seek to find the causes of a given effect.

Unfortunately time does not permit an elaboration of the four ways in which the process of experiment may be used to arrive at truth, viz., (1) by agreement, (2) by difference, (3) by residues, and (4) by concomitant variations. I may only commend them to you for careful study and must then pass on to a brief consideration of the second method by which we arrive at truth through inference, viz., the deductive method.

We have discussed the inductive method first because it is the simplest and most direct method of arriving at truth by inference. Moreover, it precedes and underlies the deductive method, for the starting point of the latter consists of one or more generalizations which presumably have already been established. It is true, as John Stuart Mill says, that "If we had sufficiently capacious memories, and a sufficient power of maintaining order among a huge mass of details, the reasoning could go on without any general propositions; they are mere formulae for inferring particulars from particulars." But as we have not such memory or power of maintaining order among details, and as, in our processes of reasoning by the deductive method we start from generalizations arrived at by the inductive method.

The mode of investigation according to which we arrive at truth by the deductive method consists of three steps: the first, one of direct induction; the second, of ratiocination, or reasoning; and the third, of verification. The inductive method consists merely in inferring from the particular to the general, but in the deductive method, starting from previous generalizations the process of ratiocination is applied, and as a result of this operation conclusions are reached which are subject to direct verification. It is a mistake to suppose that the conclusions of deduction are distinctly new, in the sense that they were not contained in the underlying inductions involved in the reasoning, and yet the truths arrived at by the deductive method may be, and usually are new in the sense that they were not recognized in the inductions which formed the basis for the reasoning. As an example of this the science of geometry may be mentioned. The theorems of geometry are all deducible from the axioms or postulates which are inductions, but in which one fails to recognize a priori all the theorems deducible from them.

The third operation in the deductive method, viz., verification, is of marked importance as we shall see later on in the more specific consideration of the methods of research.

It is evident, from the hasty outline given above that these two methods of arriving at truth by inference are not independent. The basis of the deductive method is a previous induction. The two methods are interdependent. A young or complex science will partake more of the character of an inductive science, as compared with an older or simpler science. A new science has few inductions to serve as the premises of deduction, but even in a new science an effort is made to reason from the hypothetical generalizations already reached to conclusions which on being verified by observation or experiment, strengthen the inductions from which they were deduced. Thus science grows.

I regret the necessity of this somewhat academical discussion of the methods of inference, but I see no other way of prefacing the ideas which I desire to present in regard to "The Methods of Research." As has been said, the goal of research is truth, and hence the methods of research are none other, in their general character, than the methods of arriving at truth by inference. Let us now apply the principles, which have been presented, to the consideration of the methods of research.

There are two general methods of research; that of induction, and that of deduction. The former is the method of observation and experiment, and the inference from the concrete to the general. The latter is the method of hypothesis or theory, ratiocination and verification. Let us consider these two methods more in detail.

The inductive method consists of observation and experiment. In a new science little is known, the observations are limited, the experiments are few. There is little opportunity for ratiocination or reasoning; the greater need is for the accumulation and collection of facts in generalizations which may subsequently form the basis of ratiocination. To use the illustration referred to above, we are not prepared to reason from the induction that glare is deleterious to eyesight because this induction itself is scarcely out of the domain of empiricism. We are investigating the matter; we are making observations and carrying out experiments. We are collating facts. We are doing research by the inductive method. In the development of all science, but more particularly in the development of the newer or more complex sciences, this method of research finds most valuable application.

I would further distinguish two ways of carrying out research by the inductive method which I shall call respectively the definitive and the non-definitive methods. The distinction between these two methods is best shown by reverting once more to our illustration of the effect of glare. An investigator of this subject might carry out his research in either of two ways. He might, for example, lay out a definite scheme of attacking the problem. He might study experimentally first the effect of glare on visual acuity, then its effect on speed of reading, then its effect on fatigue, and so on. He might attempt to study by the process of observation the intensity of the glaring light, the angle at which it is incident on the eye, the period over which the patient has been subjected to the glare, and the relation of these elements to the resultant eye-injury. In either of these two cases, both of which are examples of research by the inductive method,—one by the processes of experiment and one by the process of observation—the investigation has proceeded according to a definite plan, has followed a definite scheme. Such research by the inductive method I would call definitive.

On the other hand many investigations are carried out by the non-definitive method, and many investigators have a tendency to work in this way. Thus, in the illustration of the study of glare, an investigator might set out to study the problem without any definite scheme of attack, or any preconceived notions of the casual relations between the resultant effects and the possible causes. He would, in a more or less random fashion, vary the conditions and note the result, and attempt ultimately to discover the important element in the problem. The method is haphazard, fortuitous, non-definitive. And yet at times it is most valuable. Moreover, it should be emphasized that in research by the inductive method the process is seldom entirely definitive or entirely non-definitive. The investigator with the scheme is ever alert, or should be ever alert, to recognize some unsuspected phenomenon which flashes out into prominence as important. And the schemeless investigator will always, or should always follow up any phenomenon which attracts unusual attention.

The two processes are interwoven, and very few, if any, researches are made exclusively by one or the other. And yet it is very easy to point to investigators who tend to work according to one or the other of the two processes. I am at a loss what to say regarding the relative merits of the two methods. The non-definitive method is at times, and in the hands of certain investigators, of the greatest value, but I see no way of laying down rules for procedure according to this method. Since it is more or less haphazard there can be no rules. We must rely entirely on the personal equation of the individual. The definitive method, on the other hand, is conformable to a formula of procedure. Inasmuch as the general scheme of procedure by the definitive inductive method has much in common with that of the deductive method, I shall give the formula for the two at the same time.

We now turn to a consideration of the deductive method of research. This is the method of hypothesis or theory, ratiocination and verification. We have seen that this method of arriving at truth consists in argument from previous inductions or generalizations to conclusions which are subjected to verification by observation or experiment. This is peculiarly the method of the mathematical sciences. The verification confirms the conclusion and strengthens our belief in the generalizations which served as premises. These generalizations may be generalized facts as in the classical illustration—All men are mortal; or they may be generalized principles such as the theory of gravitation or the nebular hypothesis. A general principle which possibly or even probably underlies or explains certain phenomena is frequently termed a hypothesis. Arguing or reasoning from this hypothesis certain conclusions are derived. These conclusions are put to test by observation or experiment. If the conclusions are not confirmed the hypothesis is shown to be false and not to be a true induction or generalization. If the conclusions are found to be true, the hypothesis is strengthened. If the deductions from the hypothesis are found consistently to be true the hypothesis becomes a theory, and is classed with the other great principles of the science.

Just as it is impossible to lay down rules for carrying out a research by the non-definitive inductive method, so it is impossible to lay down rules for deciding upon the scheme of a research according to the definitive inductive method, or of determining upon a specific deduction according to the deductive method. These things are matters of individual creative imagination and not subject to formula. Granted, however, a definite scheme of research (definitive inductive method) or a deduced conclusion (deductive method) it is quite possible to lay down a general formula which will be helpful in carrying out the experimental work. Such a general plan of procedure is outlined below:

1. Exact definition and statement of problem.
2. Study of literature pertinent to the problem.
3. Determination of experimental method.
4. Choice or design of apparatus.
5. Isolation of specific phenomenon to be studied, or of quantity to be measured, and elimination of complicating phenomena or quantities.
6. Preliminary investigation of instruments used.
7. Investigation and discussion of sources of error.
8. Careful analysis of results.
9. Justifiable conclusions.

In an early paragraph of this paper emphasis was laid on the fact that the goal of research is truth. Whatever may be the stimulus for the attempt to ascertain the truth, whether it be truth for truth's sake, or truth as the basis of sound practice, the immediate object in every true research is truth. It seems expedient in concluding the paper to return to this subject to reiterate the importance of the right attitude toward research, and to sound a word of caution against those two classes of investigators whose well-meant efforts serve rather to retard than to assist the development of science. The charlatan, the impostor needs no consideration, but there are genuine men whose contributions in the name of scientific research are more fundamentally and permanently harmful than the wild claims of the charlatan. I refer to the narrow, incompetent investigator and to the broad speculator. The former can see but one side of a problem, and his incompetency is further reflected in his restricted ability to impose the proper limitations on his conclusions. The latter is continually inferring generalizations from inadequate data, or deducing conclusions from non-established inductions. There is a place for hypothesis, and there is need of speculative imagination, but he who confuses speculative hypothesis with established principles and leads others into such error is inhibiting the development of science. And it is very difficult to counteract the effect of such unjustifiable speculation, for it is usually in the domain of limited knowledge, and his is a thankless task who urges the inadequacy of fact to justify the speculation, but who is unable himself positively to controvert the speculation. Let us all endeavor to be more severe critics of our own work, and more discriminating critics of the work of others.

HUDSON BAY RAILWAY RISKY.

"The Hudson Bay Railway undertaking is of so risky a nature and its ultimate success is so problematical that it should be operated by the Dominion Government until its real value has been demonstrated," said Sir Donald Mann at Winnipeg. "When the Canadian Northern started we had the choice of going north to the Bay or east and west. We chose to go east and west, and I think the result has justified our judgment. But you can never tell, and the result is uncertain. Undoubtedly, there will be a large fish trade from the north and valuable mineral deposits may be found along the right-of-way, as happened in the case of the Ontario Government road, making the line of incalculable worth. Add to this that there is bound to be considerable through traffic, freight and passenger, the element of risk is materially reduced. But I think that the right course is being pursued."

THE "BOOSTER" PUMP SUPPLIED THE GREAT WESTERN RAILWAY WORKS AT SWINDON.

We give below a brief description of an interesting plant which the Great Western Railway Company have just recently installed in their works at Swindon.

The plant consists of a "Victoria" turbo pump supplied by Messrs. Jens, Orten, Boving & Company, of 9½ Union Court, Old Broad Street, E.C., coupled up to a Bruce Peebles motor.

The pump takes the water from an elevated tank at a pressure varying up to 20 lbs. per sq. inch, and delivers into a pipe-line of more than one mile in length, to which the nozzles for the work's fire system are connected, boosting the pressure up to about 120 lbs. The pump is thus inserted into a pressure water, and is therefore constantly primed and always ready for immediate starting up. It is flexibly coupled up to a D.C. motor of the protected shunt wound, commutating pole type running at 1,300 r.p.m. and with an output of 90 h.p.

The pump and motor are erected in a separate station, as shown in the accompanying figure, and are operated from the central power house some considerable distance away, starting up being done by a hand-operated liquid starter fitted with field discharge resistance.

The pump is so designed that it requires no attendance whatsoever beyond the provision of the necessary lubricant for the bearings. There are no cocks or other regulating devices of any description fitted to the pump which would require adjustment in order to overcome endthrust and consequent heating of bearings [illegible] pumps, especially when they are working against a pressure different from the normal. The patent trust balancing device fitted in this pump adjusts itself automatically to such changes of pressure as will of neces[illegible] altered or in case other supplies are taken from the main.

It cannot be emphasized strongly [illegible] liability of such installations depend [illegible]

[illegible] running. These fluctuations of pressure continued for some time owing to the inertia of the long water column in the delivery pipe, but during all these changes of load, whch constitute the severest pressure test to which a turbine pump can be put, the Victoria pump did not show any signs of heating, but proved to be balanced perfectly.

Another feature, indispensible with pumps that should require practically no attendance, is the absence of a high-pressure stuffing box. Pumps containing high-pressure glands are unsuitable for this kind of work, as these glands often require tightening and careful attention, for if set too tightly, as is often done with a view to minimize the leakage inevitably connected with high-pressure glands, the shafts or shaft sleeves become unduly worn and troubles through heating of the gland may occur, [illegible]

View of Pump Station.

With this condition the "Victoria" turbo pump fully complies as there is no high-pressure stuffing box in this pump, as only low-pressure exists in the last chamber of the pump which, in fact, forms a self-contained unit.

[illegible]

APPLICATIONS OF OIL-MIXED CONCRETE.

About a year ago Mr. Logan Waller Page, director of the Office of Public Roads, United States, made public the results of certain investigations which he had been conducting into the properties of oil-mixed concrete as a waterproof material. A summary of his findings was published in *The Canadian Engineer* of October 12, 1911. Since that time the experimental work has been progressing steadily and the latest results are published in bulletin No. 46 of the Office of Public Roads, which was issued on August 8. The first part of the report deals principally with the laboratory and service tests which were covered in detail in the issue of this journal previously referred to. The results of these laboratory investigations may be summarized as follows:

The oils used were a fluid residual oil and a cut back oil asphalt. The damp-proofing properties of concrete mixtures containing oil have been demonstrated very definitely by laboratory and by service tests which establish this material as one of great merit for certain types of concrete construction. It has also been shown that the admixture of oil is not detrimental to the tensile strength of mortar composed of 1 part of cement and 3 parts of sand when the oil added does not exceed 10 per cent. of the weight of the cement used. The compressive strength of mortar and of concrete suffers slightly with the addition of oil, although when 10 per cent. of oil is added the decrease in strength is not serious. Concrete mixed with oil requires a period of time about 50 per cent. longer to set hard than does plain concrete, but the increase in strength is nearly as rapid in the oil-mixed material as in the plain concrete. Concrete and mortar containing oil admixtures are almost perfectly non-absorbent of water, and so they are excellent materials to use in damp-proof construction. Under pressure, oil-mixed mortar is very efficient in resisting the permeation of water. Laboratory tests show that oil-mixed concrete is just as tough and stiff as plain concrete, and furthermore its elastic behavior within working limits of stress is identical with that of plain concrete. The bond or grip of oil concrete to steel reinforcement is much decreased when plain bars are used. Deformed bars, however, and wire mesh or expanded metal will reinforce this material with practically the same efficiency as in ordinary concrete.

The remainder of the report is given over to a discussion of the proper uses of the oil-mixed concrete and detailed instructions are given for specific cases. There is also an appendix devoted to the results of physical tests of oil-mixed concrete:

Oil.—For oil-mixed concrete, petroleum residuum oils conforming to the specifications given below have been found to give good results in both laboratory and service tests:

(1) The oil shall have a specific gravity of not less than 0.930 nor greater than 0.940 at a temperature of 25 deg. C.

(2) It shall be soluble in carbon disulphide at air temperature to at least 99.9 per cent.

(3) It shall contain not less than 1.5 nor more than 2.5 per cent. of bitumen insoluble in 86 deg. B. paraffin naphtha.

(4) It shall yield not less than 2.5 nor more than 4 per cent. of residual coke.

(5) When 240 cu. cm. of the material is heated in an Engler viscosimeter to 50 deg. C. and maintained at that temperature for at least 3 minutes, the first 100 cu. cm. which flows out shall show a viscosity of not less than 40 nor more than 45.

(6) When 20 grams of the material is heated for 5 hours in a cylindrical tin dish 2½ in. in diameter by 1 in. in height, at a constant temperature of 163 deg. C., the loss in weight shall not exceed 2 per cent.

Mixing.—For most purposes where damp-proofing is required 5 per cent. of oil based on the weight of cement in the mixture is all that is necessary. A bag of cement weighs 94 lb., and consequently, for each bag of cement used in the mixture, 4.7 lb. or about 2½ quarts of oil are required. The sand and cement should be mixed dry. Water is added to the mixture and the mass again mixed to a mortar of mushy consistency. Oil is then measured out and added to the mortar, and the mass again turned until there is no trace of oil visible on the surface of the mortar. Particular care should be taken to continue the mixing until the oil is thoroughly incorporated in the mixture. The oil-mixed mortar is then combined with the stone or gravel previously moistened and the mass is again turned until all of the stone is thoroughly coated with the mortar and the mass is uniformly mixed throughout. Should only oil-mixed mortar be desired, the process is similar to that above described except that no stone is added.

In a machine mixer the cement, sand, and water are first mixed to a mortar when alternate batches of oil and stone are added until the required quantity of oil is mixed, and then the remainder of the stone is added and mixed.

Uses.—All of the laboratory and service tests thus far made on oil-mixed mortars and concretes are indicative of a wide future usefulness for these materials, principally in damp-proof construction. There are many types of structures through which the permeation of moisture is ruinous to either the appearance or the efficiency of the construction, or is seriously detrimental to the health of either animal or human life. The efflorescence due to the leaching out and subsequent carbonization of the lime on the surface of a concrete wall might well be prevented by the incorporation of an agent capable of excluding all moisture. Again, the dampness of many cellars, with its danger to health, could have been prevented had the walls and floors been damp-proofed. The following types of structures might be damp-proofed at an exceedingly slight extra expense by the incorporation of a small amount of the proper kind of mineral oil residuum with the mortar or concrete used in construction: Basement floors, basement walls, watering troughs, cisterns, barns, silos, concrete blocks, roofs, stucco, and numerous important engineering constructions.

Basement Floors.—There are many basement floors which are continuously damp, owing to the percolation of moisture from the underlying soil. Concrete and mortar, as ordinarily made, are neither perfectly non-absorbent nor waterproof, so that ground water readily finds its way through to the basement and causes a very insanitary condition.

A floor which will remain perfectly dry may be constructed at a cost but very slightly higher than that of the ordinary basement floor by the incorporation of a petroleum residuum oil with the ordinary concrete mixture. The following method of construction, using an oil-cement mixture, is suggested as one which will prevent the permeation of moisture even from a very wet subsoil.

It will be well, if the underlying soil is very wet, to lay a 6-inch foundation of sand, cinders, broken stone, or gravel, compacting these materials well by tamping. In addition it will be of advantage to employ drain tiles in this porous foundation, leading them to a sewer if possible. On top of the foundation should be laid a 4-inch layer of concrete mixed in the proportions of 1 part of Portland cement, 2½ parts of sand, and 5 parts of broken stone or gravel. Before the concrete base has hardened, a top or wearing coat of mortar mixed in the proportions of 1 part of cement and 2 parts of sand or stone screenings and containing 5 per cent. of oil (2½ quarts per bag of cement) should be laid. This top coat, because of its non-absorbent character, will give perfect protection from underlying moisture, and moreover it will build a floor which will dry out very quickly after washing, since practically none of the washing water will be absorbed.

It might be thought that the addition of oil to the mortar-wearing coat would tend to make the surface slippery. Such, however, is not the case; nor is the appearance very much different from that of an ordinary cement floor. Should joints be provided for expansion and contraction, it will be necessary to fill them with a good bituminous filler to prevent the entrance of water.

Many cellar floors now made of Portland cement concrete are giving trouble owing to the permeating moisture. They are continually damp and, owing in part to the constant evaporation from their surface, they are cold. Such a condition may be remedied by the application of an oil-mixed mortar coat to the surface of the old floor. Before attempting to lay the new wearing surface, the old floor should be scrubbed thoroughly clean and should be made thoroughly wet. The bond between the old and the new work will be improved if the old surface be roughened with a stone hammer. A wash composed of 1 part of hydrochloric acid and 5 parts of water may be used to clean the surface. This will dissolve some of the cement from the old work, leaving the aggregate exposed. The acid solution should be left on not longer than half an hour, when it should be completely removed with clean water. The surface should then be brushed with a wire or stiff scrubbing brush to remove any particles of sand which may have become loosened because of the dissolving of the cement.

A mortar composed of 1 part of cement and 2 parts of sand and containing 5 per cent. of oil will be sufficiently non-absorbent for the new wearing coat. To strengthen the bond it will be well to apply a wash of grout, made by mixing cement with water to the consistency of cream, before laying the oil-mixed mortar coat. For the ordinary basement floor a 1-inch layer of mortar will prove of sufficient thickness. It will be necessary to keep the new mortar damp for at least one week in order that it may attain its proper strength.

Cellar Walls.—The entrance of moisture through the walls is another common source of damp basements. The water pressure in the soil adjacent to the wall is very seldom of great magnitude, so that a non-porous material and one that is at the same time impermeable under moderate pressures is the logical one to use for this type of construction.

A concrete mixture in the proportions of 1 part of cement, 2½ parts of sand, and 5 parts of gravel or broken stone, together with 10 per cent. of oil based on the weight of cement in the mixture, should prove amply rich for most [illegible]. A wall of these proportions, [illegible] in. thick and provided with a spread footing, will withstand a pressure of 6 ft. of earth. When supported at the top by floor joists, a much thinner wall may be used with safety. A 6-in. wall [illegible] ft. high may be used to withstand 6 ft. of earth pressure. Generally speaking, such a thin wall should be reinforced [illegible] in both directions. Smooth rods should not be used in [illegible], however, [illegible] for reinforcing, may be used with perfect results. Care should be taken that the earth is not filled in against the [illegible].

[illegible]

The surface to which this mortar is to be applied should be roughened with a stone hammer, if the old wall is of concrete, or the mortar joints should be raked out to a depth of half an inch from brick or masonry walls. The acid wash previously described should be applied to cleanse the surface thoroughly, after which the loose particles must be removed with a wire brush or a stiff bristle brush. It will be impossible to obtain a water-tight coating if it is applied while water is seeping through the wall. It will be well to wait for the dry season, when the ground water is reduced to its lowest level, before attempting to waterproof by plastering. Should water appear to be coming through a well-defined crack in the wall, calking with oakum or cotton may be resorted to in order to stop the leakage until a plaster coat of oil-mixed mortar can be applied. It will be necessary to mix the mortar for plastering to a rather dry consistency, and it should be troweled hard in order to obtain a hard, dense waterproof surface. A wash of cement and water mixed to the consistency of thick cream and applied before the oil-mixed mortar coat will aid the new mortar in adhering to the old work. The old wall must be thoroughly wet before the new mortar coat is applied.

Watering Troughs.—The use of oil-mixed concrete in the construction of watering troughs will be found to give excellent results in maintaining them in an absolutely water-tight condition.

For this purpose a mixture of 1 part of Portland cement, 2 parts of clean coarse sand, and 4 parts of gravel, ranging in size from ¼ in. to 1 in. is recommended. The mixture should likewise contain 10 per cent. of oil based on the weight of cement and should be mixed to a jellylike consistency. It will be well to provide wire-mesh or steel-rod reinforcement for the bottom and walls. Care should be taken to puddle the concrete into place thoroughly and to trowel or spade the material adjacent to the molds. This flushes the mortar to the surface, making it smooth and dense, and rendering a finishing coat of plaster unnecessary. Should a very smooth surface be desired, an effective finish may be obtained by applying several paint coats of oil-mixed cement grout made as follows: Enough water should be mixed with cement to form a paste of soft, putty-like consistency. To this paste should be added 3 per cent. of oil, based on the weight of dry cement in the mixture (a 10-quart bucket of dry cement requires about a pint of oil for this purpose), and the whole should be mixed until the oil is entirely combined with the other ingredients. The paste may now be thinned down with more water to the consistency of cream, after which it may be applied with a stiff brush to the previously dampened concrete. A second coat of this oil grout should be applied after the first coat has hardened. care should be taken that it does not dry out too quickly by applying it to the dry concrete or exposing it to the direct rays of the sun. A tank built as described will be absolutely water-tight, and, furthermore, the waterproofing will have cost almost nothing in comparison with the costs of the other materials.

Cisterns.—For waterproofing cisterns, oil mixed concrete will prove of great benefit. It is absolutely necessary that cisterns which are buried in the ground be waterproofed to prevent contaminated ground water from seeping in, as well as to prevent the cistern water from escaping. Buried cisterns of rectangular shape should be reinforced to resist the earth pressure, which tends to bulge the side walls inward when the water runs low. The reinforcement should, therefore, be provided on the inside or tension side of the walls. The earth pressure will prevent the tank from cracking when it is full of water.

For cistern construction a mixture composed of 1 part of cement, 2 parts of sand, and 4 parts of gravel or broken stone, together with 10 per cent. of oil, is effective. The inner faces of the cistern should be painted with an oil-mixed cement grout applied with a stiff brush and rubbed well into the face of the wall. Two coats of this grout, containing about 3 per cent. of oil, should be used.

Barns.—Barns constructed of concrete are gradually coming into use, because of their durability, cleanliness, resistance to fire, and economy. It is essential that the interior of these structures be kept free from moisture, and for this reason it is well to waterproof the concrete mixture entering the side walls and flooring. The side walls, unless waterproofed, have a tendency during a long beating rain to absorb and retain much moisture, and this moisture penetrates to the interior.

If oil in amount to 5 per cent. of the weight of cement be mixed with the concrete used in the side walls, this damp condition of the interior becomes impossible, because the admixture of oil prevents the penetration of the moisture.

Barn floors should be waterproofed by the addition of oil as previously described. A damp-proof floor has the advantage of remaining dry and hence warmer, because there is no evaporation from the surface. It is likewise more sanitary than an ordinary concrete floor because of its non-absorbent character.

Concrete Blocks.—The use of concrete blocks in the building trade is yearly increasing. Much criticism has been heaped on the building block, and in many cases the criticism has been just. It is recognized that many concrete block houses are damp, owing to the fact that the walls are very porous, and absorb and retain much moisture after a heavy, beating rain. A building block generally need not be waterproofed against water pressure, but it should, however, be rendered proof against the permeation of water by absorption. The use of a small quantity of mineral oil in a concrete block renders it extremely non-absorbent, so that even after a hard rain there is no danger from damp walls. In a 1:2:4 mixture, 5 per cent. of oil is a sufficient quantity to waterproof properly against absorption.

Roofs.—Portland cement mortar mixed with mineral oil and reinforced with steel-wire mesh may be advantageously used in the construction of roof slabs. These slabs could be assembled in place on the roof after they had attained sufficient hardness. Reinforced concrete tiles may also be advantageously made with Portland cement concrete mixed with a small percentage of mineral oil residuum.

Stucco.—Portland cement stucco is widely used in the construction of many residences. This type of canstruction is economical, and, moreover, with it many beautiful effects are possible. The term "stucco" is given to the exterior finish coat, which may be applied to brick, stone, concrete, hollow tile, or frame construction. According to the finish desired and the kind of surface to be covered, the stucco is applied in two or three coats. The first, or scratch coat, should be mixed in the proportions of 1 part of Portland cement and 2 parts of clean, coarse sand, with enough water to form a good, stiff mortar. If 5 per cent. of oil is added to this mixture, the scratch coat will be permanently waterproof. While this coat is still wet, it is roughened with a stick or trowel over the entire surface. The second coat, which may be of the same proportions, is plastered on after the first coat has set sufficiently to support it. The use of oil in this coat may be omitted if desired, and it may be given a rough-cast finish by using a trowel covered with burlap or carpet.

This second coat may also be applied by throwing it on with a wooden paddle. This produces a rough surface known as a slap-dash finish. A pebble-dash surface may be obtained from the use of pebbles ¼-in. in diameter, mixed with cement in the proportions of 3:1, with a mixture that is quite wet. This mixture is thrown on the second coat while it is still soft and the result is a very pleasing surface. When a pebble-dash finish is used, the second coat, as well as the scratch coat, may be mixed with oil. In most constructions the second coat will be found superfluous, because a sufficiently thick coating is usually obtained from the first application of oil-mixed mortar.

When stucco is applied to stone or hollow tile, care should always be taken to have the surface well moistened or otherwise a great deal of water will be absorbed from the mortar coat, and so greatly weaken it and cause contraction cracks to form.

Engineering Construction.—There are many important engineering constructions in which oil-mixed mortar or concrete may be advantageously employed. Among them may be mentioned aqueducts, buildings, burial vaults, boats, foundations, gutters, mausoleums, roofs, sewers, trough, tanks, and wells. In some constructions a coat of oil-mixed mortar is effective, while in others oil-mixed concrete may be used throughout.

It is confidently believed that, if carefully prepared, oil-mixed concrete is used in structures of any kind requiring damp-proofing—and in such structures careful work is a very important factor in the result—there will be no difficulty experienced from leakage and the structures will have been damp-proofed at very little extra expense.

Summary of Conclusions.—The following conclusions as to the effect of the oils used in cement and concrete may be drawn from the investigations into the physical properties of oil-mixed concrete:

(1) The tensile strength of 1:3 oil mixed mortar is very little different from that of plain mortar, and shows a substantial gain in strength at 28 days and 6 months over that at 7 days.

(2) The times of initial and final set are delayed by the addition of oil; 5 per cent. of oil increases the time of initial set by 50 per cent. and the time of final set by 47 per cent.

(3) The crushing strength of mortar and concrete is decreased by the addition of oil to the mix. Concrete with 10 per cent. of oil has 75 per cent. of the strength of plain concrete at 28 days. At the age of 1 year the crushing strength of 1:3 mortar suffers but little with the addition of oil in amounts up to 10 per cent.

(4) The toughness or resistance to impact is but slightly affected by the addition of oil in amounts up to about 10 per cent.

(5) The stiffness of oil-mixed concrete appears to be but little different from that of plain concrete.

(6) Results of tests for permanent deformation indicate that no definite law is followed by oil-mixed concrete.

(7) Oil-mixed mortar and concrete containing 10 per cent. of oil have very little absorption and under low pressures both are waterproof.

(8) Oil-mixed mortar containing 10 per cent. of oil is absolutely water-tight under pressures as high as 40 lb. per square inch. Tests indicate that oil-mixed mortar is effective as a waterproofing agent under low pressures when plastered on either side of porous concrete.

(9) The bond tests show the inadvisability of using plain bar reinforcement with oil-concrete mixtures. The bond of deformed bars is not seriously weakened by the addition of oil in amounts up to 10 per cent.

◆

EUROPEAN DEMAND FOR COPPER.

For the past few days Europe has been buying copper metal, and one of the large selling agencies in New York has sold 10,000,000 pounds at 17¾ cents per pound.

A NEW WATER PURIFICATION PLANT.

The city of Fargo, North Dakota, has recently installed a new water purification plant, the water supply being drawn from the Red River.

Originally water was used from the Red River for all purposes. It was hauled about the city and sold as a commodity. At a later date, about 1879, a pumping station was installed and water supplied through mains laid under a franchise by a water company. This source of supply and method of distribution was satisfactory until the water shed became settled and the river became contaminated by the run off from farms and possibly from sewage from the growing cities situated on the river above this city.

There were other objectionable features of the water for a domestic supply and in the early 90's a number of artesian wells were put down in the western part of the city. These wells produced a supply of good water but it was exceedingly hard, and considerable discussion was carried on from time to time as to the desirability of using a water carrying a large amount of mineral solids in solution.

The difficulty of obtaining a satisfactory supply of water led to many investigations as to ways and means of bettering it. At length the city engineer, Mr. Frank L. Anders, was directed to prepare plans and specifications for a rapid sand filtration plant. A brief description of the plant adopted, based on matter contained in Mr. Anders' latest report, is here given.

The river intake is substantially constructed of cedar piling faced with fir sheet piling to prevent any movement of finely divided silt into the wet well. The outer end of the intake is constructed so that water will be taken from as near the surface as seems desirable. It is also fitted with a screen made of flat boiler plates, which will prevent any leaves or sticks from entering the intake. The intake is connected to a wet well by two 18-inch cast iron pipe lines. The well is constructed of concrete, and in two sections. Either section may be cut out of service for cleaning for one of the purposes of the well is to catch mud before it enters the suction line. The well is fitted with the necessary valves for changing the course of the water from one chamber to the other.

From the wet well to the low lift pumps the distance is about 800 ft. and connection is made between the two by an 18-in. suction line. This line is cast iron flanged pipe and at the upper end is connected to two low lift pumps. These pumps comprise that part of the plant that lifts the water from the river and delivers it to the purification plant. The pumps are the centrifugal vortex type, built by Lawrence manufacturing Co., and are driven by Sturtevant turbines directly connected to them. The combined capacity of the two pumps is [illegible] gals. per 24 hours. The low lift [illegible]. Ample [illegible] for the installation of another [illegible] if necessary.

Upon leaving the low lift pumps the water is conducted through a [illegible] discharge line connected to the mixing chamber. [illegible] The mixing chamber is [illegible] of reinforced concrete and is [illegible] wide, [illegible] long and [illegible] deep. It is fitted with vertical baffles that cause the water to flow up and down through them, traversing a distance of [illegible] and [illegible] so that the chemical reactions may be completed. This chamber is one of the most important [illegible] in the plant and one that will have the greatest bearing on the [illegible] of the purified water.

Upon leaving the mixing chamber, the water passes into sedimentation basin No. 1. As it enters this basin a coagulant may be added which also has a very important function to perform. The coagulant, which may be either sulphite of iron or sulphite of aluminum, decomposes and forms a hydrate, also known as floc. This is a light snow-flakelike material, which makes its appearance soon after the addition of the coagulant to the water. The cross section of the basins are such as will give a very low velocity to the water, and this is necessary in order that the floc may settle and leave the water clear. The proper design of these basins is an important part of the work, for the greater part of water purification is done in them. As the floc forms and settles, it enmeshes and carries with it most of the turbidity and a great part of the bacteria, thus relieving the filters of a heavy load they would otherwise have to carry.

There are two sedimentation basins, each with a capacity of about 1,000,000 gals. In case the chemical reactions and subsequent settlement is completed in basin No. 1, the water may be conveyed to basin No. 2 and thence to the filter. Or, if the reactions are completed in No. 1, the water can be conveyed from it directly to the filters. The mixing chamber can be cut out entirely and the basins used with it or the two basins used in parallel. In order to prevent after deposits from the lime action, raw water can be added as the treated water passes from the basins. This is sometimes necessary and is the most effectual device known for this purpose.

A conduit constructed of concrete conveys the water from the sedimentation basins to the filter house and thence along the centre lines of the pipe gallery in front of the filters. Connecting the conduits to the filters there are inlet chambers fitted with proper valves to conduct the flow of water into the proper chambers.

The filters are four in number, completely installed, and two more can be completed at a small additional cost. They are constructed of reinforced concrete throughout, and are 17 ft. by 21 ft. in area. Each will have a capacity of 1,000,000 gals. per day, exclusive of wash water.

The filters are furnished with a cast iron manifold system set in concrete. On top of the manifold there is laid 10 ins. of a carefully graded filter gravel and 30 ins. of a carefully prepared silica sand. Wash water boxes, two in number, run longitudinally with the filters.

The treated water passes on to the sand from the inlet chamber, thence through the sand, gravel, manifolds, drains and controllers to the clear well, where the purified water is stored until required for use. The clear well is underneath the filters, protected from all contamination and fitted with baffle walls to keep the water in circulation.

The filters need cleaning at certain periods, and this will be accomplished by reversing the flow of water through the sand and conveying the dirty water through a sewer to the river below the dam. The sand is agitated during washing by air conveyed to it by a suitable pipe system.

The most important parts of the plant installation are the filter controllers. Careful consideration was given to all the types of controllers now in use and it was decided to use the [illegible] filter controller. The advantages of this piece of apparatus are many, and it has no equal for the duty it is called upon to perform. Its action is such as to keep the clear well full of water at all times and it will meet the varying rates of consumption without the attention of the operator.

The head house is located directly west of the filter house, and is a two-story structure of brick and concrete. In the basement there are located the wash water and air pumps, bathroom, machine shop, etc. The laboratory, superintendent's office, chemical controllers and part of the solution tanks are on the first floor, while the second floor is devoted to storage of chemicals and their preparation for addition to the raw water.

No function of a water purification plant is more important than that of properly adding the chemical solution to the raw water. The rate of consumption of water in the city of Fargo varies from about 500,000 gals. to probably about 4,000,000 gals. per 24 hours. The raw water has to be treated to meet this varying rate, and the usual method is to pass the chemical solution through an orifice having a known discharge. This orifice needs the attention of the operator in order to meet the varying rate of raw water discharge. It is at once apparent that the operator cannot do this, however faithful he may be, for he does not, at all times, know what conditions he has to meet. The whole problem is satisfactorily solved by the installation of the Earl chemical feed controller. This device automatically meets, at every instant, the varying rate at which the raw water may be passing into the mixing chamber and the proper chemical is at all times fed to the raw water at a rate proportionate to the consumption. By the use of this device over-dosing and its ill effects are eliminated, as is also under treatment of the water. The operator can rest assured that the water is at all times being properly treated.

The plant is constructed throughout of reinforced concrete, except the buildings, which are faced with Twin City terra cotta tile and lined with common brick. The roofs are trussed with steel, sheathed with fir and finished with green glazed tile.

NATIONAL STEEL CAR COMPANY.

The National Steel Car Company has been incorporated for the purpose of building and operating a plant for the manufacture of wood and steel freight cars. The location of the plant will be at Hamilton, Ont., and the head office at Montreal. The authorized capital is three million dollars seven per cent. cumulative preference stock, and three million dollars common stock, of which $1,500,000 par value preference and $2,000,000 par value common will be issued. The amount issued is considered adequate for the building, equipping and operating of a thirty-car plant, while sufficient stock is retained for future growth. The principal Canadian railroads experience considerable difficulty in placing orders with existing firms for a quick delivery, and this the National Steel Car Company begins business with an existing demand for its products. The estimated average earnings working at sixty per cent. of its capacity is given as $400,000, which is sufficient to pay the 7 per cent. dividend on the preferred stock, and leaving $295,000 available for common stock dividend.

The management of the company will be in the hands of Mr. Basil Magor, president of the Magor Car Company, Passaic, N.J., who is resigning that position which he made a success, believing in the possibilities offered in Canada. Mr. A. Butze, for many years purchasing agent of the Grand Trunk Railway, will act as the company' purchasing agent.

The cost of construction of the plant has been estimated by Messrs. Barclay, Parsons and Klapp, consulting engineers, as $649,730. The house of issue is Messrs. Brouse, Mitchell, members Toronto Stock Exchange, Colborne Street, Toronto. Sir John Gibson, Sir Henry Pellatt, C.V.O., Toronto; Messrs. W. K. Price, New York; C. H. Cahan, Montreal; M. H. Coggeshall, New York; M. Davis, Montreal; Basal Magor, Montreal; W. Barclay Parsons, New York; W. G. Ross, Esq., Montreal; J. J. Scott, and W. Southam, Hamilton, have consented to act as directors.

TO USE LOCAL WOODS IN BRITISH COLUMBIA

An idea with regard to wood creosoting was laid before the forestry branch, province of British Columbia, by Mr. Skinner, who has charge of the construction of the C.P.R. docks in Vancouver.

These docks are being built of eucalyptus wood brought from Australia. This wood is preferred because its gummy quality enables it to resist the teredo longer than will any of the native woods of British Columbia. The Douglas fir, however, if properly creosoted, will last longer than the eucalyptus. Moreover the Crow's Nest coal, it is said again, on Mr. Skinner's authority, is the best in America for creosoting purposes. These two factors combined seem to him to offer opportunity for a new industry. The idea is especially interesting to the forestry branch because if creosoted blocks can be introduced as paving material, there will be a chance to utilize much of that part of the tree which is now left in the bush and wasted.

MUNICIPAL POWER PLANT FOR GRAND MERE, QUE.

The corporation of Grand Mere, Quebec, has awarded to Allis-Chalmers-Bullock, Limited, Montreal, the contract for the complete hydro-electric power plant for municipal lighting and power purposes. The plant will include a single horizontal turbine 500 h.p. 600 r.p.m. under 100 feet head and an alternating current generator 300 k.v.a.; 3-phase, 60-cycle, 2,200-volt, 600 r.p.m. with direct connected exciter 125-volt, 600 r.p.m. The turbine will be in cast iron spiral case with quarter turn and single discharge. The runner will be of bronze cast in one piece, the guide vanes of steel and the inside parts bronze lined. The unit will be compact, easily operated and thoroughly up-to-date and will have an over-all efficiency of 80 per cent. The contract also includes an oil pressure governor, step-up transformers from 2,200 to 11,000 volts, step-down transformers from 10,000 to 2,200 volts. Service transformers 2,200 to 110 volts. Switchboards and other auxiliary apparatus. Messrs. Surveyer and Frigon were the consulting engineers.

PERSONAL.

MR. R. B. LAMB has resigned his position as consulting engineer with the Crown Chartered Mine.

MR. RALPH STOKES has been appointed as assistant to Consulting Engineer Mein, of the Canadian Mining and Exploration Company.

MR. L. S. COCKBURN, a graduate of the University of Toronto in engineering, and MR. E. L. WENGER, B.Sc., have become partners under the firm name of Wenger & Cockburn, consulting engineers, with headquarters in Regina, Sask.

MR. R. D. BROWN, city engineer of St. Catharines, Ont., has resigned from his position in order that he may be free to accept a position offered him in the services of the government, under Mr. Weller, superintendent of the new Welland Canal.

MR. E. S. JENISON, formerly with the Henion & Hubbell Company, of Chicago, Ill., has been appointed manager of the pulp department of the Canadian Fairbanks-Morse Co., Limited, who are now the exclusive sales agents in Canada for the triplex and power pumps, as well as the other lines manufactured by the Goulds Manufacturing Co., of Seneca Falls, N.Y.

MR. A. H. BERGER, until recently the secretary-treasurer of the American Spiral Pipe Works, has organized the Standard Spiral Pipe Works of Chicago. The latter company will manufacture reinforced spiral steel pipe with interlocking seam and smooth inside, for water supply, irrigation, derdging, pulp mills, etc. Mr. Berger made a trip West recently and demonstrated the merits of his pipe to a number of prominent engineers in British Columbia.

MR. C. M. WATERMAN, treasurer of The Eugene Dietzgen Company, manufacturers of drawing materials and mathematical and surveying instruments, left Toronto last week for a six weeks' tour of Western Canada, in the interests of his firm. The Canadian business of The Eugene Dietzgen Company has been growing very rapidly within the past year and, while West, Mr. Waterman will undoubtedly find many further opportunities for expansion.

COMING MEETINGS.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS, TORONTO SECTION.—First regular meeting will be held at the Engineers' Club, 96 King St. West, on Friday evening, October 4th, 1912, at 8 p.m. Secretary, W. E. Young, [illegible] King St. West, Toronto.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—Annual Assembly will be held at Ottawa, in the Public Library, on 7th October, 1912. Hon. Sec'y, Alcide Chaussé, 5 Beaver Hall Square, Montreal, Que.

THE CANADIAN HIGHWAY ASSOCIATION.—Meeting will be held in Winnipeg, Man., October 9th to 12th. Secretary, P. W. Luce, Room 4, Cunningham Block, New Westminster, B.C.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Power, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE. Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the [illegible]

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, 409 Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill [illegible]

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; [illegible]

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-[illegible] October to April, in [illegible]

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Mayor Lees, Hamilton, [illegible] Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—[illegible] Indian Head, Sask.; Sec.-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta.; [illegible]

THE UNION OF CANADIAN MUNICIPALITIES.—President, [illegible] Hon. Secretary-Treasurer, W. D. Lighthall, K.C., ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, [illegible] Hon. Secretary-Treasurer, J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Sec.-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Sec'y-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Jas. Anderson, Gen. Mgr., Sandwich, Windsor and Amherst Railway; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr, G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, A. F. Wickson; Toronto. Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, Killaly Gamble, 703 Temple Building, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263 Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box [illegible], Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

TENDERS PENDING.

In Addition to Those in this Issue.

Further information may be had from the issues of The Canadian Engineer referred to.

TENDERS.

Brantford, Ont.—Tenders for extensions to the Brantford General Hospital, including new ward building, service building, boiler house and laundry, will be received until noon of October 7th, 1912, by C. H. Waterous, president, B.G.H., in care of Messrs. Taylor & Taylor, architects. Plans, etc., at the office of the architects, Brantford.

Edmonton, Alta.—Tenders for plastering of Government House, Edmonton, will be received until October 7, 1912, by John Stocks, Deputy Minister of Public Works, Edmonton. Full particulars at the office of the provincial architect, New Parliament Buildings, Edmonton.

Hanover, Ont.—Tenders for the laying of about 16,000 sq. ft. of cement concrete sidewalks in the town of Hanover, will be received by John Taylor, clerk, town of Hanover, until October 7th, 1912. Full particulars at the town clerk's office.

Port Colborne, Ont.—Tenders sent to R. C. Desrochers, secretary, Department of Public Works, Ottawa, will be received until October 22nd, 1912, for the repair of the headblock of the east breakwater at Port Colborne, county of Welland, Ont. Plans, etc., at the office of the secretary, and office of J. G. Sing, Esq., district engineer, Confederation Life Building, Toronto, Ont., and on application to the postmaster, at Port Colborne.

Regina, Sask.—Tenders for the construction of drain in townships 31 and 32, to be received by H. S. Carpenter, acting Deputy Minister, Department of Public Works, Government of the Province of Saskatchewan, until October 8th, 1912, at whose office plans and specifications may be had.

Scott, Sask.—Tenders for the supply of 1,000 feet of fire hose with couplings and nozzles complete, will be received by James N. Forrest, secretary-treasurer, Scott, until October 7th, 1912.

Toronto, Ont.—Tenders for the construction of storm overflow sewer, Main Garrison Creek Division, Section No. 3, will be received until October 22, 1912, addressed to the Chairman of the Board of Control, City Hall, Toronto. Specifications, etc., at the office of the Commissioner of Works, Toronto. G. R. Geary (Mayor), Chairman, Board of Control. (See advt. in The Canadian Engineer).

Vancouver, B.C.—Tenders for grading and bridging of the Comox extension of the Esquimalt & Nanaimo Railway, from Big Qualicum River, mile 15½, to Union Bay, mile 34.79, will be received by H. J. Cambie, chief engineer, Vancouver, up to October 10th, 1912. Plans, etc., can be inspected at the office of R. A. Bainbridge, division engineer, of the E. & N. Railway, Store Street, Victoria.

Victoria, B.C.—Tenders to be received until October 4th, 1912, for a four-story reinforced concrete Odd Fellows' temple on View Street, Victoria. Plans and specifications may be had at the office of D. C. Frame, 1011 Government Street. Wm. Jackson (Chemist), secretary, Douglas Street.

Victoria, B.C.—Tenders for supplying 50,000 railway track ties, and distributing same on the grade of the Comox extension of the Esquimalt & Nanaimo Railway from McBride Junction to Big Qualicum River, will be received by H. E. Beasley, general superintendent, Victoria, until October 10th. Specifications can be secured on application to the superintendent, or from any station agent on the E. & N. Railway.

Whitby, Ont.—Tenders will be received until October 22nd, 1912, for the construction of a stone and concrete esplanade wall at Whitby harbor, township of Whitby, county of Ontario, Ont., at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa. Plans, specifications and form of contract can be seen and forms of tender obtained at this department and at the offices of J. G. Sing, Esq., district engineer, Confederation Life Building, Toronto, Ont.; H. J. Lamb, Esq., district engineer, Windsor, Ont., and on application to the postmaster at Whitby, Ont.

Winnipeg, Man.—Tenders for supply of labor and materials required in the erection of a frame building covered with corrugated iron sheeting to be used as a power sub-station at Transcona, Man., will be received until October 9th, at the office of M. Peterson, secretary, Board of Control office, Winnipeg. Plans, etc., at the office of the City Light and Power Department, 54 King Street.

Winnipeg, Man.—Tenders addressed to the chairman, Board of Control, will be received until October 9, 1912, for the manufacture and delivery f.o.b., Winnipeg, of 100,000 feet of No. 6 B. and S. twin conductor arc lighting cables, lead covered and armored in accordance with specifications, which may be obtained at the office of the City Light and Power Department, 54 King Street. M. Peterson, secretary, Board of Control office, Winnipeg.

Yorkton, Sask.—Tenders will be received by T. F. Acheson, secretary-treasurer, until noon of October 31st, 1912, for one 500 B.H. Diesel engine, direct coupled to alternator and exciter, and one switchboard with auxiliary panel and series tungsten street lighting apparatus. Specifications to be obtained on application to the office of M. M. Inglis, electrical engineer, Yorkton, Sask. (Advt. in The Canadian Engineer).

◆

CONTRACTS AWARDED.

Berlin, Ont.—Mr. W. Lytall has been awarded the contract to extend the lighting system from Ellen Street at a cost of $1,494.00. He is at present working on the system below this point.

Province of British Columbia.—The contract for the construction of about forty-two miles of railway between Coalmont and Coquahalla Summit was let by the V. V. & E. Railway Company, which is one of the titles of the Great Northern in British Columbia, to Guthrie, McDougall & Company. The work will cost about $1,500,000.00.

Edmonds, B.C.—The contract was awarded by the council for the laying of the pipes for the second unit of the water system of the municipality, the successful tenderers being Messrs. T. R. Nickson and Co., the amount being $40,492. Nine tenders were presented to the committee, the lowest being $38,595 and highest $48,657.

Edmonton, Alta.—The management of the Edmonton Leather and Shoe Company awarded a contract for the erection of their plant to Messrs. Congdon and Oliver. This work will cost about $25,000.00.

Montreal, Que.—The Chicoutimi Pulp Company have entered into a contract to supply the Edward Lloyds Co., of London, with 50,000 tons of pulp annually for a term of ten years.

Ottawa, Ont.—The government have decided to enlarge the government-operated elevator at Port Colborne from a capacity of 1,000,000 to 2,000,000 bushels, the contract for which has been awarded to the Dominion Bridge Company. Cost will be $201,000.

Ottawa, Ont.—A contract for a retaining wall in the harbor of Owen Sound was let, the price being $18,900.

Mr. James Bogue, of Peterboro, has been awarded the contract for the construction of a retaining wall for the Rideau Canal at Smith's Falls. The work will cost $8,190.

A suitable site has been purchased for the new public building to be erected in Fort Francis, Ont.

Council has approved of the contract for the erection of new mounted police barracks at Banff, to cost $13,865.

Port Alberni, B.C.—The contract for the construction of the Port Alberni waterworks system has been awarded to the Municipal Construction Company, Limited, of Vancouver, and work is to be commenced immediately. The estimated cost of the work is $[illegible].

Other tenders received were as follows: M. P. Cotton Company, Limited, without specials, $89,693; complete with specials, $94,559. John D. Campbell, without specials, $90,060; comulete with specials, $95,979. T. R. Nickson & Company, Limited, without specials, $98,301. Broley & Martin, without specials, $98,672. Naylor Bros., without specials, $104,398. McGillivray & Edwards, without specials, $116,336. Canadian Pipe Company, Limited, without specials, $[illegible].

Toronto, Ont.—The Department of Public Works have awarded Messrs. Gearing Brothers the contracts for masonry and carpenter work for the new Veterinary College on University Avenue. [illegible] work has been completed and [illegible] at once. [illegible] plumbing and [illegible] for some time. Cost of college [illegible].

Vancouver, B.C.—Mr. J. J. [illegible] has received the contract to erect an apartment house for Mr. L. C. Marshal at a cost of $[illegible]. [illegible] are the architects.

Victoria, B.C.—The contract for the erection of the [illegible] will be let to Mr. Edward [illegible] whose tender of $[illegible] was the lowest of several submitted.

Winnipeg, Man.—The Mitchell-[illegible] Electric Company [illegible] the contract for the supply of material and installation required for the lighting system of the Arlington Street bridge. The cost of the work is $4,175.

Winnipeg, Man.—Elevator equipment and finishing hardware required for the King George Isolation Hospital at a total cost of $10,075, will be supplied by the Otis-Fensom Elevator Co., Limited, and the Winnipeg Paint and Glass Co., Limited, respectively.

◆

LIGHT, HEAT AND POWER.

Berlin, Ont.—The following is a statement of the financial results of the operation of the municipal gas and electric light plants for the month of August last:

Gas—	
5,724,000 cubic feet @	$3,724.00
126 tons of coke @	630.00
2,240 gallons tar @	33.60
Total	$4,387.60
Operating expenses	$2,809.33
Surplus	$1,578.27
Electricity—	
Incandescent lights	$2,317.16
Power	2,173.71
Arc lights	1,072.49
Total	$5,563.36
Operating expenses	$3,139.33
Surplus	$2,424.03

Brantford, Ont.—The municipal council has prepared a by-law calling for a bond issue of $115,000.00 for the installation of a hydro-electric plant in this city. The ratepayers will vote on this on October 25th next.

Windsor, Ont.—The Edison Illuminating Company, of Detroit, have commenced construction work on a plant to supply Essex, Leamington and Amherstburg. These towns are at present supplied by small local plants, but the United States company plan to undersell them and also in time to enter Windsor and compete against Windsor, Sandwich and Amherstburg Street Railway Company.

Peterboro, Ont.—A by-law calling for the installation of hydro-electric power into this municipality will be submitted to the ratepayers at an early date. The estimates for this work are placed at $88,000.00.

Regina, Sask.—The municipal commissioners have practically decided to introduce the standard pillar arc light to the business section of the city.

Regina, Sask.—The municipal electric light plant of this city is on a paying basis. The estimated surplus for 1912 was $48,900. Up to the present the net earnings have been $46,800, and if this rate is kept up will reach $70,000 for the twelve months.

St. Thomas, Ont.—The municipal council have adopted a report prepared by Messrs. Ruth and Sumner regarding the heating system of the city hall and will spend about $6,000.00 on improvements to the present equipment. The work includes the installation of automatic stokers and asbestos covering and a considerable amount of two-inch pipe.

Wichester, Ont.—The by-law in favor of the hydro-electric power carried in the village, [illegible] voting for, and 14 against.

◆

GARBAGE, SEWAGE AND WATER.

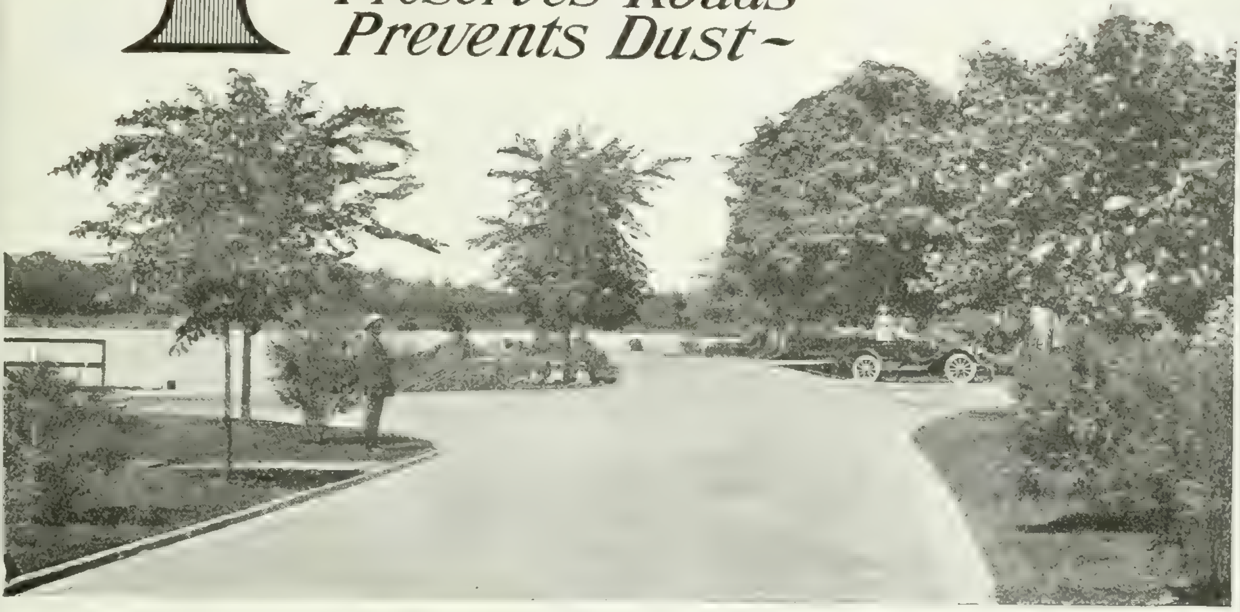
Kingston, Ont.—The Roberts Filter manufacturers of Philadelphia have made an offer to the civic utilities committee to erect and operate a filtration plant to care for the city's water supply for 8 years. The proposition will be considered.

Leaside Junction, Ont.—A report states that the Canadian Northern Railway engineers engaged on the construction of the model city are considering the installation of a private waterworks system.

Montreal, Que.—Owing to several complaints from citizens regarding the erection of a sewage pumping station on

Tarvia

Preserves Roads
Prevents Dust



Section of Government Parkway, Ottawa, Canada, treated with Tarvia B.

The Property Owners' Investigation.

IN the City of St. Thomas, Ont., the property owners on Gladstone Avenue contemplated petitioning the City Council to improve the roadways. They commissioned one of their number to visit various American cities, inspect pavements and make a report. Their investigator, Mr. E. A. Horton, visited various cities in New York and New Jersey. In his report he made the following statements:

> "I saw a 'Tarvia X' road in Rochester which extends from the city to the lake front, a distance of about six miles. It had been in use for eighteen months, and when I saw it, it was in excellent condition, with heavy traffic over it every day. I........inspected a piece of road in Newark........the surface when finished was smooth, and to my mind was one of the finest pieces of road it was my privilege to see. We then inspected another piece of 'Tarvia X' which had been done by the Road Commission two years ago........Constant heavy traffic passes over this road every day, and trucks have loads of from 6 to 8 tons Steel-tired drays were used with most of their heavy traffic. This piece of road, as I saw it, did not show any wear whatever, and was apparently in as good condition as when it was put down.
>
> "I did not confine my attention to Tarvia roads as I saw (here he mentioned five of the commonest types of road treatment) and every other kind of road that is known.
>
> "I must say after making enquiries from people who were in no way interested, nor did they know I was seeking information, that everyone had a good word to say for the Tarvia road. I have no hesitation in recommending it for use on our street, and at the estimate cost that has been given us, after seeing the many pieces of road that I have seen, I think it is the cheapest road that can be built."

The foregoing is quoted from the St. Thomas, Ont., Journal on February 20th, 1912. Since that date Gladstone Avenue has been constructed with Tarvia X.

Anyone who will investigate the road problem with the same thoroughness will reach similar conclusions. Tarvia is made in three grades:

"Tarvia X" for use in constructing roads and pavements.

"Tarvia A" for hot surface applications.

"Tarvia B" (applied cold) for dust prevention and road preservation.

Booklet describing the latest developments in methods for building tarviated roadways and pavements will be sent free on request. Address our nearest office.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER
THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST JOHN, N.B. HALIFAX, N.S.

Place Royal the municipal council have given an order for a new site to be selected. This is a small park and the only green spot for many blocks.

Montreal, P.Q.—The municipal council have ordered the opens of the trunk sewer enlarged in order that snow taken off the streets may be dumped in and disposed of. If the scheme should work with satisfaction there will be a saving of $150,000 per year in the cost of removing snow.

North Toronto, Ont.—The council will endeavor to secure permission from the government authorities to issue $85,000.00 in debentures for a sewage system without referring the matter to the ratepayers.

Winnipeg, Man.—The Board of Control have appropriated the sum of $15,000 to defray the expense of a survey and cost of the estimate of the Shoal Lake water scheme recently reported upon. Col. Ruttan will be in charge of this work.

◆

BUILDINGS AND INDUSTRIAL WORKS.

Province of British Columbia.—Colonel A. D. Davidson, president of the Canadian Western Lumber Company, states that a cedar mill having a capacity of 125,000 feet daily, will be erected near the Fraser Mills of the company. It will cost $350,000, and will be completed in time for the spring trade.

Edmonton, Alta.—The specifications of the Grand Trunk Pacific Hotel call for 12,000 barrels of cement, 6,000 yards of sand, 10,000 yards of gravel and 1,500,000 bricks. The contracts for mill work, plumbing, heating and ventilation, roofing, sheet metal work, and iron work, will be awarded in the near future. Mr. E. Wilman, of the Canadian Stewart Company, Montreal, will receive the tenders.

Fort William, Ont.—Another storage elevator is announced for Fort William, also a seventy-five thousand dollar warehouse.

Moose Jaw, Sask.—The municipal council have sold a site on which a number of Winnipeg business men will erect a 200,000-bushel grain hopper and a 1,000,000-bushel elevator. The company will take the name of the Great West Grain Company.

Stratford, Ont.—The plant of the Canada Iron Corporation is to be enlarged in order that the manufacture of car wheels may be increased from 150 per day to 225. The addition will be of reinforced concrete 75 x 75.

Toronto, Ont.—A report states that the directors of St. Andrew's College will erect a new educational building at York Mills, Ont., and will dispose of their present holdings in Rosedale for residential purposes.

Toronto, Ont.—The management of the Christie-Brown Company, biscuit manufacturers, will erect a large addition to their present plant.

Toronto, Ont.—According to a report the new post office will be erected on the corner of Spadina Avenue and College Street. The building operations are to be commenced next spring.

Toronto, Ont.—The plans for the new military barracks [illegible]

Vancouver, B.C.—A report states that Mr. L. C. Gilman, [illegible]

Victoria, B.C.—Mr. Wm. Jackson, secretary of the building [illegible] ber 4th.

Welland, Ont.—[illegible]

Windsor, Ont.—[illegible]

BRIDGES, ROADS AND PAVEMENTS.

Edmonton, Alta.—Ratepayers have presented a large petition calling for the paving of Alberta Ave. from First Street to the railway tracks.

Leaside Junction, Ont.—A large gang of roadmakers has started work on the Canadian Northern Railway model city site.

Peterboro, Ont.—The council have asked the ratepayers to endorse a debenture issue to the amount of $70,000.00 for the erection of a new traffic bridge across the Otonabee River. The by-law will be submitted in January next.

Winnipeg, Man.—The engineering department of this municipality will expend the sum of $8,800 on plank sidewalks and $10,500 on granolithic walks.

◆

FIRES.

Almonte, Ont.—The shoddy mill of Mr. R. W. Lees was destroyed by fire with a loss of $25,000.

Galt, Ont.—The plant of the Galt robe factory was totally destroyed by fire with a loss of $150,000. Mr. Stauffer is the manager of this company but is at present in Vancouver.

Gananoque, Ont.—Fire in the plant of the St. Lawrence Steel and Wire Company caused sufficient damage to the plant to cause a suspension of manufacturing for a few weeks.

Halifax, N.S.—The premises known as the George C. Cook warehouse was destroyed by fire with a loss of $60,000. The chief occupants were offices and groceries. George C. Cook is the owner.

◆

CURRENT NEWS.

Province of British Columbia.—A company is under formation for the purpose of working the kelp on the Pacific Coast. This is a seaweed and exists in abundance along the coast of semi-tropical countries and is gathered in great quanties by coastal dwellers in Europe. It is often a profitable source of potasium salts and iodine.

Province of Manitoba.—Over $10,000 of an increase in net revenue in August over the preceding month is shown by the first monthly report of condensed earnings of the Manitoba Government telephones.

Montreal, Que.—It is understood that three new pulp mills will be started in Canada next year, one in Ontario and two others on the St. Lawrence.

Montreal, P.Q.—The Chicoutimi Pulp Co. have just entered into a pulp contract. This concern has agreed to supply Edward Lloyds Co., London, with 50,000 tons of pulp annually for a term of ten years.

Moose Jaw, Sask.—The city engineer, Mr. J. Antonisen, has prepared a report on the municipal engineering work conducted in this city during the past few months. It is shown that a tremendous amount of sidewalk and pavement work has been accomplished. The excavation for the high-pressure dam has been started and 725 building permits were issued with a combined representative value of $1,48[illegible]

Northern Canada.—Engineers and surveyors in the employ of the Alberta, Peace River and Eastern Railway Company, which proposes to build a new transcontinental line from Hudson's Bay to the Pacific Coast by way of Edmonton, have started on ponies on a trip of more than 2,000 miles into the north country to survey the route. They will meet the [illegible] party at Lesser Slave Lake and tramp [illegible] miles, finishing the trip on dog trains and return in twelve months. The party is in charge of M. Edwards.

Ottawa, Ont.—The tenders for the construction of ships to operate between Canada and the West Indies have proved a disappointment to the department of trade and commerce. Only one tender was received.

Regina, Sask.—Bricklayers in this municipality have caused considerable inconvenience to local contractors by de-

'CARLTON' SPRINKLERS AT LINCOLN (ENGLAND)

The City Engineer, R. A. MacBrair, Esq., writes

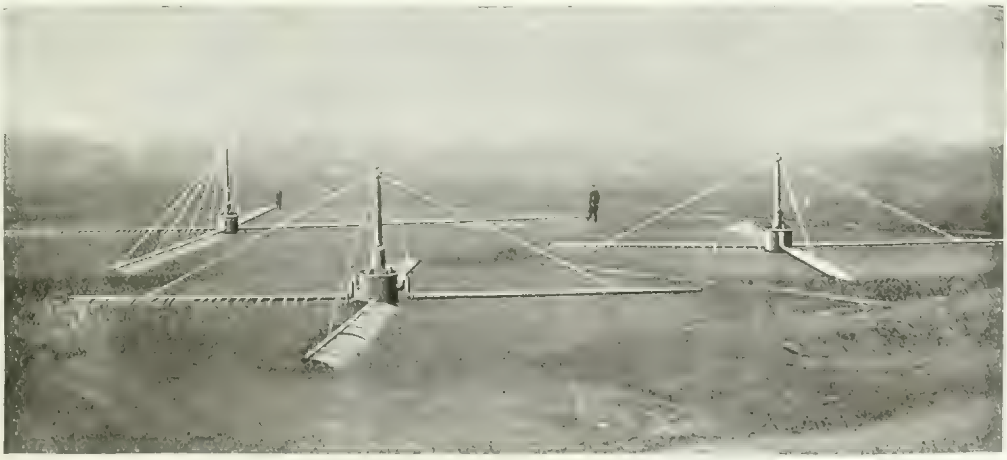
April 18th, 1910

DEAR SIRS,

I have to inform you that the three sprinklers, one 107 ft. 6 in. and two 45 ft., which you supplied us with and fixed in November last, are working well and giving me satisfaction.

Yours sincerely (Signed) R. A. MACBRAIR.

A Detailed Specification giving thicknesses of metal, is sent out with every estimate.



Every machine is guaranteed to be of the best workmanship and material.

claring a strike for higher wages. They were receiving 67½ cents per hour and struck for 70 cents.

Toronto, Ont.—Estimates for the widening of Teraulay Street call for an expenditure of $600,000.00.

Winnipeg, Man.—The government of Manitoba have awarded a prize of $10,000 to Mr. F. W. Simson, of Liverpool, England, for his plans of the proposed new government buildings. Mr. Simson has been spending a holiday in Banff but will confer with the government committee in a few days.

TRADE INQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the high commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending September 16th, 1912:

A South Wales firm of coal exporters are desirous of communicating with actual buyers in Canada.

A correspondent in Ireland is in the market for large supplies of cardboard sections, such as are used in packing eggs, and would like to hear from Canadian manufacturers.

A South of England firm of motor, electrical and general engineers desire to get into touch with buyers of petrol, gas and oil engines.

An Anglo-Canadian company recently formed to supply British-made engineering appliances to the Canadian market, desire to get into communication with purchasers and users of machinery in the Dominion.

A firm in Portugal wish to hear from Canadian importers of bottle corks.

From the branch for city trade inquiries, 73 Basinghall Street, E.C.:

A company operating a number of well-known building stone and granite quarries, chiefly in the West of England, would like to do business in Canada.

A firm in East Anglia wish to get into touch with Canadian firms who can contract for regular supplies of prime Quebec birch squares or scantlings, to specification. They also desire quotations for beech and maple square.

CANADIAN PATENTS.

The following is a list of Canadian patents secured through the agency of Messrs. Ridout and Maybee, 59 Yonge Street, Toronto:

Canada: F. H. Headley, bassinette or perambulator; F. H. Headley, spring mountings for vehicles; J. S. Campbell, production of artificial leather and rubber from seaweed; F. J. Pike and H. Neville, apparatus for operating bulkheads; W. F. Gunson and W. Park, tellurian; D. W. Rees and W. G. Moreton, drawgear of railway vehicles; S. C. Caddy, skipping appliances and physical exercising devices; [illegible] Recklinghausen, apparatus for sterilizing liquids (ultra-violet rays); Gatland Gilberd, oil lamp stoves; Henry Atkinson, chain feed mechanism.

GREAT PLANS FOR PACIFIC COAST

News comes from Ottawa that the Department of Marine [illegible] development on the Pacific Coast. In this connection it is announced that False Creek is to be dredged from the mouth to Main Street, that is the whole length of the creek [illegible] South Vancouver [illegible] Burrard will be cleared for navigation purposes. [illegible] department [illegible] West [illegible] development has [illegible] Vancouver has [illegible] False Creek [illegible] Captain [illegible] when he entered the Creek. And as the tide had turned and [illegible] that the outgoing current betokened a large river which might indicate the existence of the northwest passage which was much sought for about that time. He named it False Creek, but if the dredging is carried out as proposed it will have to be called Vancouver's Second Harbor. With industries and warehouses on either side of it, this harbor will be as busy as Burrard Inlet, with its larger interests.

Ten years ago, when the city began to develop, interest in False Creek was renewed. Mr. Roy, engineer from the department of works, made a complete survey, and it was thought at that time that the department had realized Vancouver's future needs and was about to make a channel in False Creek for low tide. Mr. Roy has been forgotten, and talk of False Creek development has recurred a dozen times. The recent decision of the present department of works may be the cumulative effect of all this discussion and preliminary work. Anyway, there is no necessity now to make a survey or seek for information. All this is ready. The announcement is that a channel 300 feet wide and 20 feet deep at low tide will be dredged. This will give excellent fairway for the craft that seek the creek, and will enable warehouse and property owners to construct wharves.

Moreover, the Canadian Northern has signified its intention to co-operate with the city and the government in the dredging of False Creek. It is almost a certainty that the city and the railway company will get together in the matter of the latter securing the remainder of the land in the False Creek basin at its head, namely 114 acres, for the company has shown that it is willing to meet the city in almost any way. It will mean an immense change in the large area lying directly east of the Main Street bridge, for all improvements must be completed within five years and three-fifths in three years. It looks as if this new railway, young and aggressive, will beat the Great Northern to it, despite the fact that the Great Northern has had a good start. It is beginning to find that it has to rush things along.

Sir Thomas Shaughnessy was on the coast recently and announces much development on the part of the Canadian Pacific Railway. Sir Thomas is no more prone to talk than most railway presidents, but now that a start has been made on what it is proposed to do, he is not unwilling to tell something. Three or four years ago, when The Monetary Times announced that a new Canadian Pacific Railway depot was planned for Vancouver, a vigorous denial came from Canadian Pacific Railway officials, yet to-day work is being pushed on the exact site then mentioned. Perhaps these things are kept in the background that other railways might not know what their competitor has in view. Anyway, this work is being done, the line is being double-tracked to Calgary, and Sir Thomas announces that more steamers are to be supplied for the coastwise business, equipment will be installed here to take care of grain for export, and new steamers are in hand for the trans-Pacific route. When the Grand Trunk Pacific was first talked of, the remark was heard that that railway might outshine the Canadian Pacific Railway. At the rate the Canadian Pacific Railway is going, the Grand Trunk Pacific will be quite a small little line compared with its older competitor. It will, however, have a fine territory to itself and what is being done in the southern part of the province will doubtless be duplicated in the north as development proceeds and occasion warrants.

Now that Point Grey has settled the tram franchise question, Burnaby is having a tilt with the British Columbia Electric. Point Grey, or rather a certain section of its people, insisted upon their rights, with the result that the municipality lost a season's development and in the end started again just where it left off. Burnaby has not so much to lose if it wins out in the court in its attempt to invalidate the franchise granted by the council, since it has not so many miles of railway to be stilled. An interesting point in connection with the Burnaby test case is advanced, namely, that the British Columbia Electric has no right to operate lines in any part of British Columbia. Counsel for the municipality is arguing that the British Columbia Electric is an English company which has obtained a license to carry on business in this province and therefore comes under the Provincial Companies Act and is restrained from operating street railways or trams in the province. The defence is that in the early days of Vancouver when tram companies were formed, a charter was obtained from the provincial government. Another charter was secured for the interurban line, and when the British Columbia Electric bought out the stock it took over all the privileges awarded in successive acts.

THE TRIPLEX BLOCK

REASONS FOR SENDING TODAY FOR THIS BOOK.

Triplex Block built into a 10 ton geared trolley and used for loading on floats lying alongside a pier in New York City.

A Book on the Handling of Loads, the Latest Practice Here and Abroad.

The change is coming fast. Modern plants today are equipping throughout to give each workman easy mastery over any load up to 20,000 lbs.

The new practice is to reduce all loads to one-man manageable loads, from the raw material coming in to the completed material going out. This frees the factory from an enormous waste. The primitive way of pitting time-paid muscle against stubborn weight, soon costs any manufacturer who stands for it a fortune in wages and restricts his output.

Months of research were spent by Yale and Towne engineers to make this book cover a wide range of conditions, so the man who sends for it will find it the most practical and helpful book that ever came to his desk.

Send for a free copy now, before
the thought is out of your mind.

Triplex Blocks { **16 Sizes:** One-fourth of a ton to forty tons.
{ **9 Active Stocks** all over Canada.

Every Block Tested to Fifty Per Cent. Overload.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured [illegible] fee.

17516—September 10—Authorizing C.L.O. & W. (C.P.R.) to construct across G.T.R. by overhead crossing, in Lot 23, Con. A, Tp. Hamilton, Co Northumberland, Ont., mileage 121.52, from Glen Tay.

17517—September 17—Directing G.T.R. to protect William Street, Lon- [illegible]

17518—September 18—Authorizing G.T.P. Branch Lines Co., to construct its railway between its Battleford and Cutknife Branches; to cross highways; and establish terminals at Battleford.

17519—September 18—Authorizing C.L.O. & W. (C.P.R.) to construct road allowance between Lots 2 and 3, Con. 1, Tp. Hope, Co. of Durham, Ont., mileage 125.36, from Glen Tay.

17520—September 18—Authorizing C.L.O. & W. (C.P.R.) to construct across ten (10) highways, from mileage 110.96 to mileage 121.26, and from [illegible]

17521—September 17—Authorizing C.N.O.R. to construct bridge across Ottawa River, at Portage du Fort, mileage 59.8 from Ottawa.

17522—September 18—Amending Order No. 17221, August 13th, 1912, by substituting plan "A."

17523—September 19—Authorizing C.P.R. to construct siding 500 ft long, connected with its railway near Bryce Avenue, Toronto, Ont.

17524—September 18—Authorizing C.N.O.R. to construct across C.P.R. by overhead structure, on Lot 6, Con. 4, Tp. McKim, Dist. of Sudbury, Ontario.

17525—September 18—Approving location C.P.R. station at Jeannette, on Lot 6, Con. 4, Tp. Tilbury East, Co. Kent, Ontario.

17526—September 19—Relieving C.P.R. from further protection at crossing [illegible]

17527—September 18—Authorizing C.P.R. to construct spur for Milverton Furniture Co., at Milverton, Tp. Mornington, Co. Perth, Ontario.

17528—September 18—Approving change in location of C.P.R. station building at Batiscan, Que., on Lot Cadastral, No. 443, Range 1, Parish St [illegible]

17529—September 18—Authorizing G.T.R. to construct two (2) additional tracks across the Cote St. Paul Road, Montreal, P.Q.

17530—September 18—Approving revised location G.T.P. Ry. through Noon-La Indian Reserve, mileage 395 east of Prince Rupert, Coast Dist., Range 5, B.C.

17531—September 18—Approving revised location G.T.P. Ry. from east line, Lot 478, to west line N.W. ¼ Lot 6028, mileage 49.26 to nileage 58.17, Range 4, Dist. Fort George, B.C.

17532—September 20—Authorizing C.P.R. to open for traffic double track from L'Acadie to point just north of diamond crossing of G.T.R., at St. John's, Que., about 3.60 miles.

17533—September 21—Extending time within which G.T.R. complete new station and rearrange yard at Hensall, Ont., for a period of sixty [illegible]

17534—September 19—Authorizing C.N.O.R. to construct across public road on Lot 18, between Ranges A and 1, Tp. Westmeath, Co. of Renfrew, [illegible]

17535—September 19—Authorizing C.N.R. to construct across public road between Secs. 3 & 4, Tp. 31, R. 12, W. 4 M., on its Goose Lake Ex- [illegible]

17536—September 19—Authorizing C.L.O. & W. (C.P.R.) to construct [illegible]

[illegible]

[illegible] mileage [illegible]

[illegible]

17548—September [illegible]—Directing G.T.R. to construct station at Whitehall, Ont.

17549—September 21—Rescinding Order No. 16460, which authorized C.P.R. to construct branch line for Inland Coal & Coke Company, Limited, at Merritt, B.C.

17550—September 20—Authorizing Rural Municipality of Progress No. 351, Saskatchewan, to construct highway over tracks of C.P.R. Macklin-Kerrobert line, where said line intersects the boundary line between Secs. [illegible]

17551—September 20—Granting leave to corporation of city of Edmonton, Alta., to open Eighth St., East, across Edmonton, Yukon, and Pacific Ry., in city of Edmonton, Alberta.

17552—September 21—Directing G.T.R. to restore joint rate per ton on brick charged from Bradford, Pa., to Windsor, Ont., prior to April 20th, 1912.

17553—September 24—Approving location C.L.O. & W. (C.P.R.) from mileage 125.5 (from Glen Tay) in a south-westerly direction through portion of Tp. Hope, thence across town Port Hope, Co. Durham, Ont., to mileage 127.32; and rescinding Orders 16977, July 6, 1912, and 17330, August 2nd, 1912.

17554—September 24—Authorizing C.P.R. to open for traffic Nakusp and [illegible]

17555—September 23—Authorizing C.P.R. to construct spur for Maple Lake Lumber Company, in W.½ Lot 27, R. 12, West of Township of Spragge, Dist. Algoma, Ont.

17556—September 24—Authorizing C.P.R. to construct spur 436 feet in Northwesterly direction across Outremont Yard, and across property of Montreal Light, Heat & Power Company, being Lot Cadastral No. 634, Parish of St. Laurent, Counties of Hochelaga and Jacques Cartier, Que.

17557—September 23—Approving location C.N.O.R. station grounds at [illegible]

17558—September 23—Authorizing C.N.O.R. to construct across public road, Lot 9, Con. 2, Tp. Gibbons, Dist. Nipissing, mileage 266.5 from Ottawa.

17559—September 23—Authorizing C.N.R. to construct across public road between Secs. 3 and 4, Tp. 29, R. 7, W. 4 M., Goose Lake Extension.

17560—September 23—Authorizing C.N.O.R. to construct bridge across Stony Creek, Tp. of Fitzroy, Co. Carleton, mileage 34.4 from Ottawa, and to divert Jimmy's Creek.

17561—September 24—Temporarily approving Standard Freight and Passenger Tariffs, C.R.C., No. B. 4, and C.R.C., No. A. 1, respectively, of the Western Canada Power Company, Ltd.

17562—September 25—Authorizing T.H. & B. Ry. Co. to construct spurs [illegible] Ltd., Hamilton, Ontario.

17563—September 25—Authorizing G.T.R. to construct siding for the Campbell Flour Mills Co., Ltd., Toronto, Ontario.

17564—September 25—Extending time, within which the Central Vermont Ry., ballast line between St. Lambert and Waterloo, Marieville and St. Cesaire, Farnham and Frielsburg, and Iberville and Farnham, until 15th November, 1912.

17565—September 24—Approving revised location Burrard Inlet Tunnel & [illegible] British Columbia.

17566—September 24—Approving location Burrard Inlet Tunnel & Bridge Co.'s railway from station 4.56.3 to station 324.32, B.C.

17567—September 25—Approving Esquimalt & Nanaimo Ry. Co., plan [illegible] Canyon, at bridge [illegible]

17568—September 23—Authorizing C.P.R. to construct spur for Elmore & Snyder, N.W. ¼ Sec. 6, Tp. 23, R. 3, W. 5 M., near Laggan, B.C.

17569—September 23—Authorizing C.P.R. to construct additional track across St. Thomas & Deschamps Sts., city of Three Rivers, Quebec.

17570—September 25—Approving C.P.R. plan showing replacement of existing trestle at bridge 37.6, Walkerton Subdivision.

17571—September 23—Authorizing C.P.R. to construct road allowance, between Secs. 35 and 36, Tp. 10, R. 32, W. P. M., Sask., across tracks of Reston to Wolseley Branch, mileage 36.01.

17572—September 24—Amending Order No. 16998, July 13th, 1912, by sub- [illegible] in fifth and twentieth lines of page two of the Order.

17573—September 23—Authorizing C.P.R. to construct spur for the J. C. Graham Co., Ltd., on Lot D.G.S. 7, outer two miles, St. John, Winnipeg, Man.

[illegible] Authorizing C.P.R. to construct spur for [illegible] Cornellier & Jolly, near Angus Station, across Subdivision Lots 138 to 147, (inc.) of Lot Cadastral No. 7, of the incorporated village of Cote de la Visitation, Co. of Hochelaga, Que.

[illegible] Authorizing C.L.O. & W. (C.P.R.) to construct across and divert road allowance between Lots 16 17, Con. 1, Tp. Hope, Co. Durham, Ont. [illegible] from Glen Tay.

17576—September 21—Authorizing C.N.R. to construct across and divert public road between Sec. 33, Tp. 30, and Sec. 3, Tp. 31, R.12, W.4.M., on its Goose Lake [illegible]

[illegible] Authorizing C.N.R. to construct across Seven (7) [illegible]

17578—September 25—Authorizing C.N.O.R. to divert St. Davide St., in [illegible] E. & N.W. sides of its right of [illegible]

[illegible] Port Arthur.

[illegible]

[illegible] York, Ont. [illegible]

[illegible] Authorizing C.N.O.R. to construct across and [illegible] Ottawa [illegible]

An Engineering Weekly

STEEL TOWERS FOR OVERHEAD TRANSMISSION LINES.

By ALFRED STILL, M.Inst.E.E., M.Am.Inst.E.E. *

It cannot be said that there is at the present time a standard type of steel structure for supporting the conductors of overhead transmission lines; neither is it likely that one particular design will ever be found suitable for all countries, climates and voltages. Any kind of supporting structure which will economically fulfil the necessary requirements will answer the purpose of the transmission line engineer, who merely requires a durable mechanical structure to carry a variable number of insulators at a height above ground, and with a spacing between them, depending upon the voltage of transmission and the length of span.

As a substitute for wood poles, steel tubes have been used, either in one piece, or built up of a number of pieces of different sizes in order to economize material and give a large diameter at the bottom where the bending moment is greatest, and a small diameter at the top where the bending moment is negligible. Steel poles of considerable height, suitable for longer spans, may be built up of three or four vertical tubes of comparatively small diameter jointed and braced together at suitable intervals to give stiffness to the structure. It is doubtful whether, in the long run, such composite tubular structures will hold their own against the latticed steel masts built up of standard sections of rolled steel, as used extensively on the continent of Europe, and, to a relatively smaller extent, in America. The term "tower" is applied mainly to the light steel structures in which the spacing between the main upright members, at ground leved, is large compared with the height of the structure; the usual proportion—which will generally be found to be the most economical in material—being 1 to 4; that is to say, if the base is square, the side of this square will be about one-quarter of the distance from the point of measurement to the top of the tower. If the towers are large, the footings are usually separate pieces which are correctly set in the ground by means of a templet, and to which the legs of the tower proper are afterwards bolted. A good example of large steel towers is to be found in the 100,000-volt transmission line of the Great Western Power Co. of California. Two three-phase circuits are carried on these towers, the vertical spacing between the cross-arms being ten feet. There are three cross-arms, each carrying two conductors—one at each end. The horizontal spacing between wires is 17 feet on the two upper cross-arms are 18 feet on the lower cross-arm, which is 51 feet above ground level. No conductor is closer than 6 ft. 5 in. to the steel structures, this being the minimum clearance in the horizontal direction. The average distance between towers is 750 feet, and they are joined at the top by a grounded guard wire 5 feet above the bottom of the highest cross-arm. The base of the tower measures 17 feet square, the parts under ground being separate pieces of steel, buried to a depth of 6 feet, to which the tower proper is bolted after being assembled and erected on site.

* Chief Electrical Engineer, mining department, Algoma Steel Corporation.

line; it is generally similar to the standard towers with wide base, as used on straight runs for moderately long spans, except for the special arrangement carrying the larger number of insulators.

The term "tower" is also frequently applied to the "flexible" type of structure which has two main vertical members only, and is specially designed to have ample strength and stiffness in a direction at right angles to the transmission line, while it is free to bend, within certain limits, in a direction parallel to the line, without being permanently deformed. Great strength and stiffness in the direction of the line is not always necessary or desirable in a transmission line support; but it is obvious that the strength and stiffness must be sufficient to withstand the forces imposed on the structure during erection, and at the time of stringing the wires. A simple braced "A" frame steel tower of the "flexible" type is illustrated in Fig. 3. This photograph shows the steel and wood pole lines running side by side between Taylors Falls and Minneapolis, Minn. These towers are 42 feet high from ground level to bottom insulator, and have a standard spacing of 440 feet.

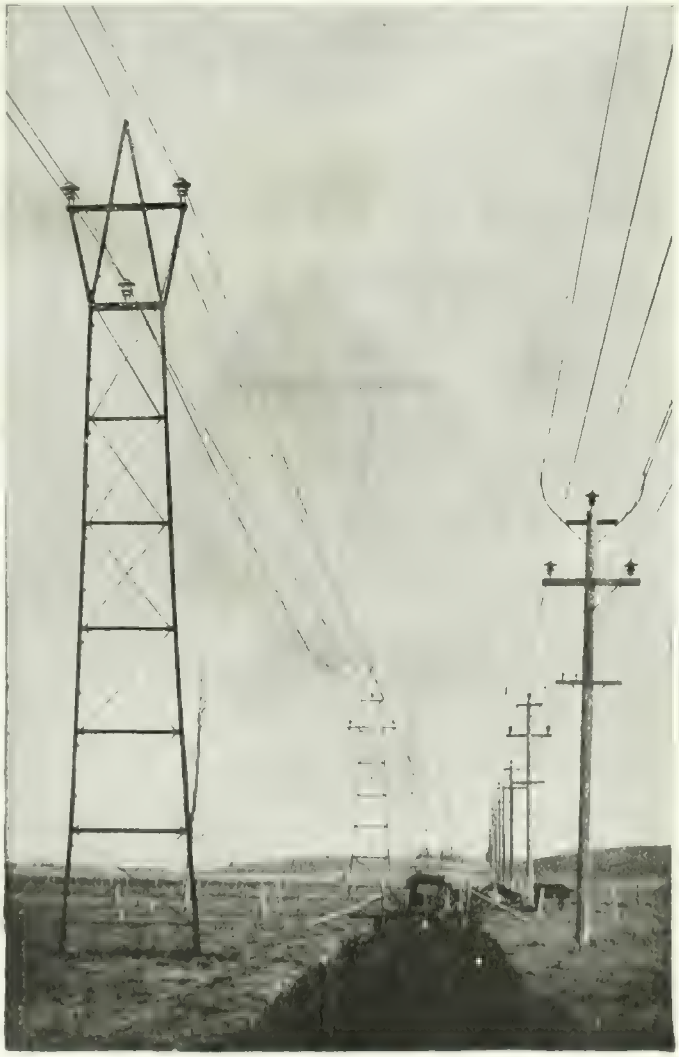

Fig. 3.—Simple Braced "A" Frame Steel Tower.

The maximum load which a tower must be designed to withstand will depend upon the number and size of wires to be carried and the estimated ice coating and wind velocity. Apart from the wind pressure on the structure itself, the loading in a direction transverse to the line will be equal to the resultant wind pressure on all the wires (which may or may not be ice coated, depending on the climate); the effective length of each wire being the distance between supports.

In the direction of the line the forces are normally very nearly balanced, but in the event of one or more wires breaking, the unbalanced load may be considerable, and it is well to design the towers, if possible, so as to withstand the stresses imposed upon them if two-thirds of all the conductors in one span are severed. On the other hand, it is not possible to tie the conductors to the insulators in such a manner that the wires will slip, or the tie break, before the conductor itself is strained beyond the elastic limit of the material (about half the breaking load). It must not be overlooked that if the wires break in one span only, the [illegible] of pin type insulators are each will be subjected to a twisting moment, and if the strain in the wires is at one end only of the cross-arm, the whole tower is subjected to tortional strain

In Vol. XXV. (January to June, 1911) of the transactions of the Canadian Society of Civil Engineers, Mr. W. G. Chase gives some interesting particulars of the steel tower line from the municipal hydro-electric works of the city of Winnipeg at Point du Bois Falls. The supporting structures are of the "flexible" type, two designs being used, one for firm soil and one for swamp construction; the height being 42 feet. Braced towers are placed at intervals of about 1,200 feet and these were tested up to 6,200 lbs. applied at one end of the cross-arm 43 feet above ground in a direction perpendicular to the line. The test pull in the direction of the line was 7,200 lbs., corresponding to 1,200 lbs. per pin. The "flexible" towers are designed to have the same strength as the braced towers to resist wind pressures across the line, but they are intended to withstand only 480 lbs. in the direction of the line. The weakest point in the line is the wrought iron insulator pin which is intentionally designed to yield before the structure is damaged; these pins withstood on test a load of 1,500 lbs just before breaking. The towers carry six aluminum wires each of 278,600 circ. mils section. These conductors are tied securely to the braced towers, but on the flexible towers, the tie is designed to break with a pull of 80 to 100 lbs.; number 14 soft aluminum wire being used for the ties. This line is 77 miles long, and it transmits power at 66,000 volts.

The normal length of span on steel tower lines usually lies between 400 and 600 feet, but very much longer spans can be used where the character of the country would render their use economical, or where rivers have to be crossed. On the transmission system supplying Dunedin City, New Zealand, with electric energy at 35,000 volts, there is a span 1,700 feet long where the line crosses the ravine near the power station. The peculiarity of this span is the great difference in level between the two supports, the upper tower, which is a special steel structure, being 650 feet above the lower tower.

The 22,000-volt transmission lines of the Canadian Niagara Power Company cross the Niagara River near Buffalo in two spans, the longest being 2,200 feet long. The minimum clearance above water level is 131 feet, necessitating very tall supporting towers. These are of steel, arranged to carry nine 500,000 c.m. aluminum cables with a 13-foot spacing. An attachment consisting of a steel cable passing over a sheave and provided with counterweight, maintains a constant tension on the conductors and takes up variations in length due to changes of temperature.

On the high tension transmission lines of the Central Colorado Power Company, there is a single span 2,500 feet long. The St. Joquin River is crossed by a 3,000-foot span. The 100,000-volt lines of the Great Falls Power Company between Rainbow Falls and Butte, cross the Missouri River in a single span 3,034 feet long.

The longest span in the world is 4,200 feet across the Coquiney Straits.

The tower illustrated in Fig. 4 is 70 feet in height; it is used for supporting one end of a span about 1,000 feet long, where the transmission line crosses a river.

Having determined the maximum load to which the towers of a transmission line are likely to be subjected, it is usual to leave the strength calculations and details of design to the manufacturer; but the calculation of the stresses in the various members of a simple steel structure such as a transmission line tower, is comparatively easy, by making use either of graphical methods **(parallelograms of forces)**, or the method of moments. A structure of this sort, when fixed to solid foundations and submitted to abnormal loads, is very liable to yield through the buckling of the members in compression, and the chief task of the designer is so to arrange and proportion the bracing and tying in of the compression members that the unbraced sections of these members shall not be unduly long.

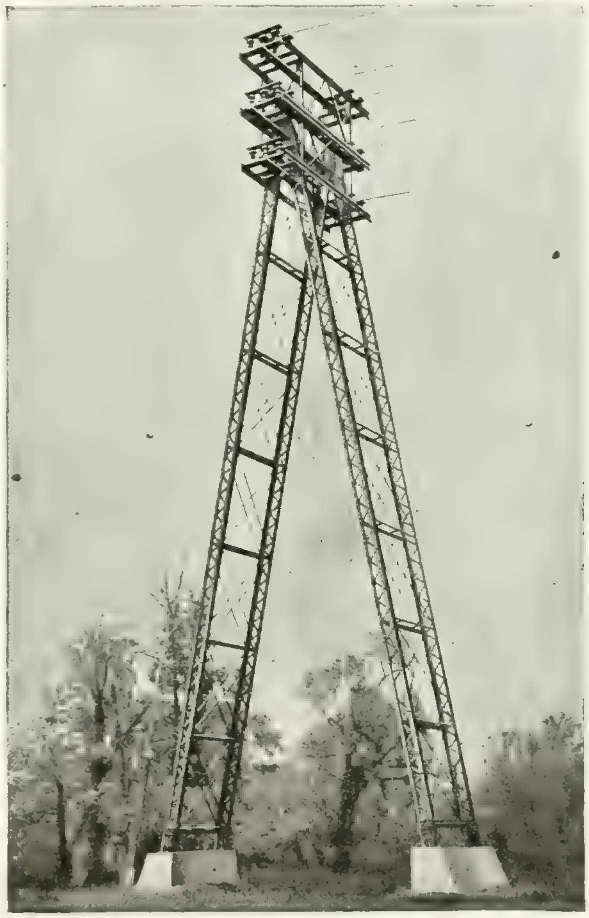

Fig. 4.—Steel Tower at River Crossing.

Rankine's formula for compression members is:

$$\frac{\text{Load :}}{\text{Area of Section}} - \text{lbs. per sq. Inch of Section} = \frac{T}{1 + C\,\frac{l^2}{R^2}}$$

Where T – maximum stress in metal in lbs. per sq. inch.

l = length of unsupported compression member.

R = least radius of gyration.

$$= \frac{\text{moment of inertia}}{\text{area of section}}.$$

expressed in the same units as l.

C = a constant, which is about 1/25,000 for mild steel struts fixed at both ends.

By using the "straight line" formula, very similar results are obtained. For wrought iron angles and tees, with ends fixed, Burr gives:

Ultimate lbs. per sq. inch of cross section = 44,000 — 140 l/R, this value being multiplied by 1.25 for mild steel. To obtain working load, divide by factor of safety.

The "straight line" formula should only be applied when ratio l/R lies between 40 and 200, which corresponds to a length of compression member not exceeding about 20 times the width of flange.

When leaving the design to manufacturers, the specification for steel towers might with advantage contain a clause to the effect that the length of the compression members shall not exceed 200 times the least radius of gyration of the section. Also in the case of painted structures, it is best to allow no metal less than ¼ in. thick. If the metal is galvanized, it may be 3/16 in. and even as thin as ⅛ in. in the case of the secondary members. It is not usual to paint galvanized iron work, partly because the extra protection hardly justifies the expense, but also because ordinary paint does not adhere properly to a galvanized surface. Special paints can be obtained, but, generally speaking, the choice lies between a galvanized structure without paint, and a non-galvanized structure which must obviously be well protected with paint. The first cost of the latter is usually lower, but the coating of paint is not so durable as the galvanizing. Sometimes the parts in the ground only are galvanized, the rest being painted.

When a tower takes a "permanent set" under excessive load, this is often due to slight yielding of the joints before any buckling of compression members takes place.

In regard to the factor of safety to be allowed in the design of steel towers, a factor of three is sometimes called for, and this is a safe figure; but it is usually sufficient to allow a factor of two under the severest expected conditions of loading; which means that, under such conditions, the structure would be stressed to the elastic limit. This factor of safety probably corresponds to a factor of about five under normal conditions of wind and ice loading; moreover, it is unnecessary to allow a very large factor of safety in such structures because abnormal stresses are nearly always moderated by the slipping of the wires in the ties, the slight yielding of the foundations or joints, or similar movements which tend to relieve such abnormal stresses as might otherwise wreck the supporting structures.

The deflection, or movement of the top of a steel tower under load is usually small, and unless the towers are specially designed of the "flexible" type, the strain is rarely sufficient to modify the tension in the wires to any appreciable extent. The design of steel tower line with the object of providing considerable elastic yielding of the supports in the direction of the line, is a special and rather difficult problem which has been dealt with by other writers, and also elsewhere by the present writer.*

The deflection of the top of a transmission tower of the ordinary light "windmill" type with wide square base, when bolted to rigid foundations and subjected to a horizontal load such as to stress the material up to nearly the elastic limit, might be from two to five inches, while the more slender latticed masts of the type shown in Fig. 1 would have a greater deflection.

The following table, which gives the deflections of built-up tubular steel poles of the type shown in Fig. 5, has been compiled from some interesting figures published in the "Standard Handbook" for electrical engineers.

---

* "Electrical World," Vol. 60, No. 2, page 97, July 13th, 1912

D_1	t_1	D_2	t_2	D_3	t_3	Weight of pole lbs.)	Maximum horizontal (load elastic limit)	Deflection (inches)
10	1/2	8 5/8	3/8	7 5/8	9/32	1342	2800	5.572
9	7/16	8	11/32	7	9/32	1099	2000	6.020
8	3/8	7	5/16	6	1/4	846	1600	7.852
7	5/16	6	1/4	5	3/16	600	900	8.217

When making comparisons between wood and steel for transmission line supports, it is not only the matter of first cost that has to be considered. Steel structures have the advantage of being invulnerable to prairie and forest fires; moreover, owing to the longer spans rendered possible by the stronger and taller supports, there is less chance of stoppages owing to broken insulators, and less leakage loss over the surface of insulators. A fact that is often overlooked is that the size of conductor limits the practical length of span; for instance, with a small conductor such as a No. 4 B. & S., it would not be wise to have spans much above 250 or 300 feet. This suggests what is frequently found to be the case, namely, that the total cost of a line may be reduced by using a conductor of rather larger section than the electrical calculations would indicate as being necessary because the stronger cable permits of a wider spacing of the supports and towers.

Fig. 5.

The life of a steel tower line depends somewhat on climatic conditions. In Great Britain the dampness of the climate, together with the impurities in the atmosphere in the neighborhood of manufacturing and populous districts, render light steel structures less durable than in America (except, perhaps, on the Pacific coast, where special precautions are required to guard against rapid corrosion due to the prevalence of fogs and moisture). Not only has the iron work protected by paint to be repainted on the average every three years, but [illegible] as the present ownership of valuable property renders the construction of a straight transmission line with long open spans almost impossible in the United Kingdom. These conditions are all in favor of the employment of selected and well creosoted wood poles, the life of which may be 20 years or more.

It is well to test the quality of the galvanizing on steel towers before erecting. This is readily done by immersing samples in a solution of sulphate of copper (specific gravity about 1.186) maintained at a temperature of 60 to 70 degrees Fahr. After remaining in the solution one minute, the sample should be removed, thoroughly washed in water and wiped dry. This process should be repeated four times, after which there should be no red spots indicating copper deposit.

The nature of the foundations necessary for steel towers will depend on the height of the tower and the pull to be resisted. In unsuitable soil it may be necessary to use concrete blocks to which the legs of the tower can be anchored; but in solid ground the concrete can generally be dispensed with. The shape and depth of the footing under ground must be such that the weight of concrete (if any) and the weight of packed earth shall be sufficient to prevent the upward pull due to the maximum horizontal load at the top of the tower.

A factor of safety of two is usually allowed. The weight of concrete may be taken at 140 lbs. per cubic foot, and of good earth at 100 lbs., the volume of the earth to be lifted being calculated at the angle of repose, which may be about 30 or 33 degrees with the vertical, as indicated in Fig. 6. If the footing of a tower is in gravel or a mixture of sand and loam, tightly packed, there is actually a far greater resistance to the pulling up of the footings than that which is offered by the mere weight of the footings with prism of earth as calculated the usual way.

Bedding of

Fig. 6.

When concrete has to be used, it is generally cheaper to reinforce it with steel of an inverted T form, as this makes a lighter construction than a solid block of concrete, and an equally good hold is obtained owing to the increased weight of the packed earth which has to be lifted. In marshy or loose soil, or where the right-of-way is liable to be flooded, special attention must be paid to the design of durable foundations. Concrete footings with or without piles, or rock-filled cribwork may be necessary; it is a matter requiring sound judgment, and preferably previous experience on the part of the engineer in charge of construction. Crumbling hillsides are best avoided; it is extremely difficult to guard against damage by landslides or even snowslides when towers are erected on the steep slopes of hills.

The Hydro-Electric Commission of the Province of Ontario, Canada, have a total exceeding 280 miles of high tension line, supported on steel towers spaced on the average 550 feet apart. They use concrete only where necessary. The standard double circuit tower measures just over 56 feet from ground level to the top. The leg angles with steel footings are buried not less than 7 feet in good ground. In rock, a footing of concrete is usually made to level up the four feet of the tower, and holding down bolts are let into the rock to a depth of not less than 2 ft. 6 in. and grouted in. When a deep footing is necessary in poor soil, the concrete block for each leg will measure about 1 ft. 9 in. square at the top and something over 3 foot square at the bottom, with a base about six inches thick and four feet square, the total depth being approximately 7 feet, with only a small portion—usually less than a foot—appearing above ground level.

Steel towers are usually shipped in sections and assembled on the ground before erection. Sometimes they have to be erected in pieces from the ground up, but usually the structure is stiff enough and light enough to allow of the complete tower being raised from the ground by using a team of horses and the necessary poles with block and tackle.

The illustrations of steel towers and structures which accompany this article have been kindly furnished to the writer by the Archbold-Brady Company, of Syracuse, N.Y. The photographs represent the latest American practice in steel pole line construction.

◆

A STADIA IN GEORGIAN BAY, DISTRICT OF PARRY SOUND.

A stadia survey affords a quick and accurate method for the location and mapping of land. Mr. A. G. Ardagh, in a paper presented to the Association of Ontario Land Surveyors gives a description of the methods used on a stadia survey in Ontario.

Instructions for this survey were dated March 19th, 1910, and the survey was temporarily commenced a few days later. It was the intention of the Surveys Branch to have base lines for triangulation measured on the ice in preparation for the summer survey, and this could have been accomplished if the exceptionally warm weather of March in last year had not rendered the ice unsafe. I had hoped to use the ice to run a closed transverse completely around the district assigned to me, and at the same time leave bases for triangulation. An attempt to do this was made, but accomplishment was defeated by the state of the ice.

The survey was definitely commenced on April 18th. The backbone of the survey was a run of triangulation along the main open channels closing on itself, now and then, where the channels made this possible. The bases were measured with a 5-chain tape, wherever the ground was suitable. Such places were not easily to be had except at the outer reefs, and they varied from 5 chains to 20 chains in length. Starting from a measured base, the length of the next base was calculated trigonometrically, and compared with the actual measurement of the new base, which gave a check on the work in between. All angles were read singly and then doubled, as a check both upon sighting and reading, and all three angles of the triangle were read and totalled to 180 degrees. The instruments used were a D.L.S. Watt Transit, 6-in. diameter, a Bausch & Lomb 4-in. (a very fine instrument), with a Foster for spare. The instruments only read to minutes, half minutes being estimated; adjustment was frequently necessary to the angles. The bearings were checked by astronomic observation every now and then, with an error of a minute or two. For plotting, the latitudes and departures of the main courses were calculated. In two instances in cycles of triangulation of 15 miles each the error in the lats. and deps., as calculated, was over 1/10th of one per cent. Although in the arrangement of pickets, selection of angles, etc., no great precision was aimed at, but only quick, practical results, yet I do not see the necessity for an error of this amount, and believe it was not wholly due to merely cumulative error. All township posts found on the mainland were tied in by triangulation.

The man doing the triangulation had a small board on which he plotted the triangles to scale on sheets. The angles were adjusted, if necessary, and the bearings and sides calculated following round each triangle and checking back on the first side. The triangulations points were indicated by the Greek letter Δ and the turning points by the letter "T." Where more than one transit is engaged on the stadia work, each transit man should have his subscript to prevent confusion where the same numbers are used by each man, and the numbers should be marked on the pickets.

The stadia transitman takes the copy of the triangulation sheets with him that affect the part he is working in, and where passing triangulation point, sets up at it and checks and corrects his bearings thereby. I think the stadia wires are best adjusted at 10 chains, so that exactly ten links are read on the rod. There will be a slight error over and under this distance, but of no practical account in intermediate readings.

Apart from the triangulation, the work consisted of a multitude of short shots, and for this the stadia wires appeared to be most apt and quickest, although I had a micrometer with me. The shots might average 8 or 10 chains, and rarely went up to 20 chains, even on turns. The transitman reads the rod and enters the distance first, reading his vernier while the rodman moves on, and no second instrument has to be consulted.

Stadia parties consist of three—transitman, rodman and steerman—the two latter together in a canoe. At first I furnished the transitman with a skiff, but latterly found that no time was lost by having the canoe men come back for him, as they had plenty of time to do it while he checked his bearings, marked his picket, made his sketches and got ready to move.

The Watt instrument read four ways to 90 degrees and one way from zero to 360 degrees, so that readings could be taken either in quadrants or on azimuth; the latter is less productive of error, as occasionally the wrong quadrant is entered in the notes, and in any case it is one more tax on the mind. The Bausch & Lomb could only be read on azimuth, and so some of the readings had to be converted in the office to quadrant bearings. To obviate reduction as much as possible, the readings were entered both ways from north to south with this instrument. Although errors in quadrant may generally be detected in plotting, yet a little time in the field may save a lot of worry in the office, and it is important to be sure of the bearings of the traverse before you pick up your instrument. The following, I think, is a good method of ensuring accuracy: Having brought the instrument from the last turning point with vernier clamped and lower limb free, sight on the back point, seeing also that the vernier has not shifted, and after taking intermediates, set the forward point, then turn again on the back point and see that lower limb has not shifted since setting up, then set the vernier at the forward reading and note if the wire intersects the picket. It has happened that where the instrument has been carried clamped from one station to another, the bearings have checked out on closing the traverse, but owing to reading of one course having been entered wrongly, the work would not plot. We don't need to be told how to do work nearly as much as we need to have hammered into us that any neglect of system to effect a temporary saving of time will make us pay dearly in the end.

The loose-leaf system was employed and found satisfactory. Holders with strong springs and which fitted easily into the pocket were used. The field notes were drafted to scale. The scale first adopted was too small and necessitated the enlargement of portions. The northerly part of the work was drafted to a scale of 4 chains, and even this cramped the notes, as the exhibited sample will show.

Search was made for township posts along the coast. The township of Harrison was surveyed thirty years ago, the surveyor now being deceased. The country has been burnt over, or both timbered and burnt, and a great many of the posts have been destroyed. The original blazed trees were found in some instances. We made a stadia survey of the coast which, based on the triangulation, produced a good result. Following the indentations of the shore, we surveyed 95 miles of main coast line, mostly in one township. The original coast line of Harrison is more or less imaginary, no actual traverse having been made in the original survey.

The islands were marked by either substantial posts or blazed trees, and the number of the island painted on the rock in white. Roman numerals were used by instructions. This was done in advance by a party of two, who also kept a list of islands and posts, and described the unpatented islands, while the notes of the transit party following after furnished a final check and the position of the tree was tied in by distance and bearing. This was the work of a moment when the rodman was passing it. Any items overlooked in the proper order consumed a lot of time afterwards in picking them up.

◆

STEEL HIGHWAY BRIDGES.

Mr. Neal Garver, instructor in structural engineering at the University of Illinois, stated in a paper presented before the Illinois Society of Engineers and Surveyors some months ago that during several years' experience in bridge work with a large company he had observed on more than one occasion that the contractor did not attempt to slight either the fabrication or erecting work on railroad bridges, but in the case of a highway structure far less care was exercised on many occasions.

In the construction of small steel highway bridges, it is an exception to inspect the steel before it leaves the fabricating plant, which Mr. Garver regarded as a mistake. There are many details, some of considerable consequence, which can be easily remedied at the shop, but are difficult or expensive to change in the field. For example, some ¼-in. lacing bars were used on a bridge where 5/16-in. bars were required. In another case, Lomas nuts of the same size were used for 3 and 3¾-in. pins; the nuts were all standard size for the 3-in. pins, but for the 3¾-in. pins the recess in the nut was insufficient to pass over the shoulder of the pin. In still another case the specifications required all finished [illegible] to be painted with white lead and tallow before leaving the shop. This was mentioned on the shop drawings. It was further required that the masonry and shoe plates on which the expansion rollers moved should be oiled. The pins were unoiled and had become quite rusty, the rollers had been painted with a heavy black paint, and the masonry and shoe plates were unplaned. The structure was a truss span with adjustable counters in the frames. In order to give the required net section, the [illegible] should have been upset, but they were not. On a [illegible] [illegible] [illegible], upon the shop drawings called for the [illegible] and [illegible] to be riveted [illegible], and the [illegible] of the [illegible] field riveted. Instead of being riveted as required, the bridge was put out completely bolted, [illegible] two members being [illegible]. In [illegible] points on the [illegible] and [illegible] had been [illegible] by shop errors, the specifications under which the bridge was inspected required the adjustable [illegible] [illegible] to be [illegible] per cent. [illegible] that [illegible] [illegible] [illegible] directions the efficacy of the new bridge was made only 80 per cent. of what it should have been.

Mr. Garver is of the opinion that many of the weak points in small steel highway bridges, due to defects of erection, can be traced directly to the foreman. He believes that poorly driven steel rivets are to be found on practically every highway bridge job. Well-driven rivets require both care and experience, qualifications usually lacking in the foremen for such work. It is not unusual to find rivet holes filled with cement and painted over. Turned bolts furnished for highway bridge work are often machine or pressed bolts turned down about 1/16 in. smaller than the rivet hole and not to a driving fit, as required by specifications. Real turned bolts are turned out complete from the steel bar.

The packing of pins is often carelessly done, and sometimes the foreman is hardly to blame for this because no sketches are given on the drawings to indicate in what order the bars are to be placed on the pins. Without such a sketch it may happen that the bending moment on the pin will be much greater than it was calculated to receive. Constant trouble is experienced in forcing the foremen to place collars on the pins to keep the bars in their proper positions in the tension members of the bridge.

In the design of highway bridge details, a common point of weakness is the connection of the floor beams to the posts, which is lacking in rigidity. Sometimes the post is so detailed at this point as to reduce its efficiency materially in taking compressive stresses. For example, the post may be made up of two channels laced, and the floor beam suspended below the bottom chord. The channels are cut off above the bottom chord eye-bars to clear the eye-bar heads and only narrow plates are extended down to carry the floor beam. The omission of any provision to carry the outside end joists where they come close to the shoe and cannot rest on the masonry is often observed in plans.

Mr. Garver's suggestions for improving highway bridge work are as follows:

1. In states having highway commissions the highway engineer should get up standard shop drawings for all spans in common use. The drawings should be carefully checked, all poor details eliminated and all mistakes corrected.

2. All fabricated materials should be carefully inspected by an experienced man before being shipped from the fabricating plant. This will eliminate all shop errors, intentional or otherwise, and provide first-class work to go into the field.

3. The work should be carefully inspected in the field after erection and before its acceptance.

4. All companies bidding on this class of work should be given due notice of what to expect, so there can be no complaint of its enforcement.

5. Mr. Garver believes that there is only one price basis fair to both parties concerned, and that is a pound-price basis.

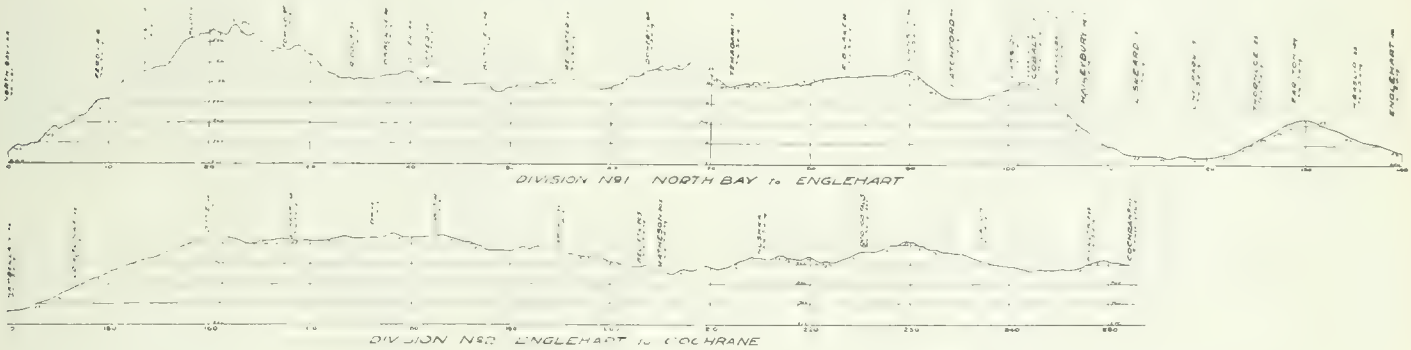
6. The bids should be called for, not for a single bridge at a time, but for the steel bridges for the entire state for a full year, on a pound-price basis, bids being called for on each class of work, with a maximum and minimum tonnage to be ordered under those bids. The objection to this system might be that it would eliminate the small bridge companies. The time has arrived, Mr. Garver considers, when economy should be practised in public as well as private affairs, and it is quite certain that private corporations would not use the methods that have been in vogue generally in the management of public business. If the small bridge companies can do as good work at the same price as the larger concern, they would not necessarily be eliminated.

GRADE REDUCTIONS ON THE T. & N. O. RLY.

The following discussion on the question of grade reduction on the T. & N. O. Railway is abstracted from a report by the chief engineer, Mr. S. B. Clement, to the T. & N. O. Railway Commission contained in the annual report of the commission:

The main line of the T. & N. O. Railway between North Bay and Cochrane is a natural connecting link, between the Grand Trunk Railway of Eastern Canada and the Grand Trunk Pacific Railway of Northern Ontario and Western Canada. That this is so, is manifested by the fact that the G.T.R. is now negotiating with the Commission for the privilege of routing its through, passenger and freight traffic to and from the G.T.P. Railway via the T. & N.O. Railway.

That section of the T. & N.O. Railway between North Bay and New Liskeard was located as a colonization railway and placed under construction before the National Transcontinental was projected. Later when N.T.C. Railway was decided upon, it became apparent that if the T. & N.O. Railway were to be extended from New Liskeard to a connection with the N.T.C. Railway it would receive from the latter a large volume of traffic in addition to what would be developed with the growth of the country, opened by the T. & N.O. Railway itself. The maximum grades on this new N.T.C. Railway were understood to be 0.4 per cent. against eastbound and 0.5 per cent. against westbound traffic, with all grades fully compensated for curvature, the sharpest curves being 4°. The same standards of grades and alignment were adopted by the Commission for the extension of the T. & N. O. Railway from New Liskeard to the Transcontinental Railway. As actually located, however, the maximum grades on the National Transcontinental Railway are 0.6 per cent. against westbound traffic, instead of 0.5 per cent. The maximum grade on the T. & N.O. Railway between New Liskeard and Cochrane is therefore slightly less than the maximum grade against westbound traffic on the National Transcontinental Railway.



DIVISION Nº1 NORTH BAY to ENGLEHART
DIVISION Nº2 ENGLEHART to COCHRANE

Profile of Main Line of T. & N. O. Railway.

Uniform and definite maximum grades do not appear to have been adopted or rigidly adhered to at the time of the location and construction of the section between North Bay and New Liskeard. In general, grades in both directions up to 1 per cent. not compensated for curvature, were freely used on all portions of this section while 1.25 per cent. grades not compensated were used in several places between North Bay and the summit in Merrick Township at M.P. No. 23. The ruling grades over the first division therefore, are equivalent to 1.2 per cent. south bound, and 1.45 per cent. north bound when compensated for curvature, curvature as sharp as 6° having been freely used on maximum grades.

The difference between the physical characteristics of the two sections of the railway is strikingly shown in the following table:

	North Bay to New Liskeard.	New Liskeard to Cochrane.
Distance	112.6 miles	140.0 miles
Ruling Gradient—North Bound	1.45 %	0.5 %
South Bound	1.2 %	0.4 %
Maximum Curvature	6°	4°
Curvature per mile	83°18′	27°56′
Tonnage Rating (10 wheel class)—		
North	560 tons	1,460 tons
South	700 "	1,710 "
Maximum Tonnage Rating (New Consolidation Class)—		
North	1,070 tons	2,700 tons
South	1,290 "	3,160 "

A very large proportion of the operating expenses necessary to handle a given traffic varies directly as the number of trains it is necessary to operate. Any increase in the trainload, whether resulting from a reduction in the ruling grade or an increase in the power of the locomotives, will reduce the train mileage, and proportionately decrease the operating expenses. In general, it has been well established that capital expenditures on grade reduction are economically justifiable and to be recommended, whenever the resulting reduction in operating expenses is greater than the interests on the capital expenditure.

During the year a series of surveys was completed that had been carried on intermittently since 1906, to determine to what extent it was practicable to reduce the excessive grades between North Bay and New Liskeard. The shorter and lighter of these grades can be reduced without changing the alignment while the longer and heavier can only be eliminated by rebuilding on a new location, in some cases at a considerable distance from present right of way. Wherever these diversions have been necessary actual locations have been made and estimates of cost prepared.

The most striking feature of the accompanying profile of the T. & N.O. Railway is what is locally known as the "Merrick Summit," just north of North Bay. The elevation of the North Bay yards at the C.P.R. Junction is 652 ft. above sea level and from Riddle north for 25 miles, the general elevation of the country is approximately 1,000 above sea level. The intervening "Merrick Summit," with an elevation of 1,300 ft. above sea level, is the most serious obstacle to be overcome. In the original location, this summit was crossed by deflecting several miles to the east from North Bay, following the rugged shores of Four Mile Creek, and the North River to the summit. After an exhausted examination of the country on both sides of the right of way, it was found that a lower grade from North Bay could be obtained by following Duchesnay Creek and the summit could be crossed at an elevation of about 1,170 ft. or about 130 ft. lower than the present summit, connecting with the present line at M.P. No. 35, just north of Riddle. If at all possible, it is desirable, that the ruling grades on the first division should not exceed those on the second division, but it is a physical impossibility to obtain an 0.5 per cent. grade north from North Bay. This diversion, North Bay to Riddle, has been located with maximum curvature of 4°, and with maximum grades of 0.8 per cent. northbound and 0.6 per cent. southbound, all compensated for curvature. The cost of construction will not be excessive. The diversion gives the lowest grade that can be obtained from North Bay without swinging the line far to the west to the Sturgeon River Valley. With this diversion as a key to the situation it will be unprofitable to attempt to lower the grades between Riddle and Liskeard below 0.8 per cent. northbound and 0.6 per cent. southbound.

Having adopted these ruling grades, every grade in excess of them, between North Bay and New Liskeard, was carefully examined. It will not be necessary to reduce a number of the shorter of these grades as they may be operated as momentum grades. The reduction of the grade between New Liskeard and Cobalt from 1 per cent. to 0.6 per cent. can only be accomplished by a diversion that would pass at a considerable distance from the present station grounds, at Haileybury and New Liskeard. For this reason, it is advisable, for the present, to overcome this grade by means of a helper engine service.

The following summary statements show the proposed method of reducing all grades between North Bay and New Liskeard to a maximum of 0.8 per cent. northbound and 0.6 per cent. southbound:—

Table Showing Reduction of Grades—North Bay to New Liskeard.

Location, mile to mile.		Method of Reducing Grade.	Estimated Cost.
2.	35	Diversion	$1,482,500
40	41.2	Train filling	50,120
47.9	48.5	"	25,610
51.7	52.5	"	11,000
[illegible]	[illegible]	"	39,100
[illegible]	[illegible]	"	33,280
[illegible]	[illegible]	"	9,200
[illegible]	[illegible]	Diversion	307,075
[illegible]	[illegible]	Train filling	16,225
90.	94.	Diversion	220,000
[illegible]	[illegible]	Train filling	8,400
[illegible]	[illegible]	Helper Engine Service	....
		Total	$2,20[illegible]

The total length of the North Bay-Riddle diversion will be thirty miles, replacing thirty-three miles of present line. The curvature on diversion averages [illegible], and on the present line [illegible] per mile.

The total rise and fall is as follows:—

	Rise.	Fall.
Present main line	[illegible]	[illegible]
Diversion	[illegible]	[illegible]

◆

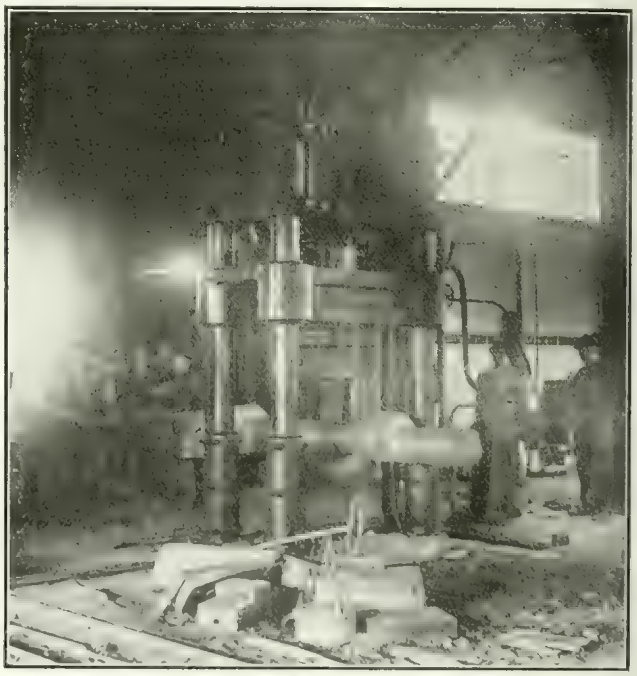
Professor W. W. Andrews of Regina, is engaged in making a study of the coal and clay deposits of the southern part of the province for the Saskatchewan government. In connection with the fuel problem the professor has succeeded in making briquettes from lignite and also from straw. In regard to the latter he claims that out of five tons of straw he can manufacture [illegible] of straw briquettes, which will be [illegible] to the best firewood.

A NEW FORGING PRESS.

There has recently been installed at Welland, Ont., by the Canada Foundries and Forgings, Limited, in the Canada Forge plant, a high-speed hydraulic forging press of German design. The press was built in the United States and is one of the first of its kind in Canada.

The problem which this new press has been designed to solve is that of forging the metal by pressure instead of by repeated hammerings. Heretofore, the process of shaping the metal to its different forms has been accomplished by hammer, in which the hammer head, urged at high velocity, beats the mass of metal into shape by a series of blows. This process naturally is accompanied by tremendous shock and vibration.

The new high-speed hydraulic forging press recently installed by the Canada Forge Company, operates at shorter range. It kneads the metal by a press head, which, after being brought into contact with the metal, is urged by tremendous force, which works the mass not only at and near the surface, but through to its centre. The new press is a 500-ton one, and, being of the hydraulic type, is more efficient than the steam press. Water pressure at 3,000 pounds per square inch is supplied by high-speed pumps driven by A.C. motors direct connected.



View of New High-Speed Hydraulic Forging Press Installed by Canada Foundries and Forgings, Limited, Welland, Ont.

Serving the press are two electric gib cranes, one on either side, which carry the billets from the two large furnaces especially constructed for the purpose. A third large furnace is now being installed for annealing and heat-treating carbon and alloy steels.

An interesting electric, modern welding equipment has recently been installed in the Canadian Billings & Spencer plant, also at Welland, which concern is another of the subsidiary companies of the Canada Foundries and Forgings. This electric welding equipment is used constantly on automobile and carriage work, for which it is especially adapted. The company is also carrying out extensions in order to put into operation a new five thousand pound steam hammer early next year.

THE COQUITLAM-BUNTZEN HYDRO-ELECTRIC POWER DEVELOPMENT.

The Coquitlam-Buntzen Water Power System is owned and operated by the Vancouver Power Company, Limited, a subsidiary company to the British Columbia Electric Railway Company, Limited, operating in the city of Vancouver, British Columbia, and the surrounding towns and districts over an area of 1,600 square miles. Mr. Charles A. Lee, assistant engineer of the Vancouver Power Company, describes the enlargement of this development in an article published in a recent issue of the Engineering Record, from which the following details are taken. This power system was first put in operation in December, 1904, replacing a steam plant which had been used up to that time.

The Buntzen power house is at sea level on the east side of the North Arm of Burrard Inlet, about 16 miles from Vancouver. The original installation consisted of four 1,500-kw. generators driven by Pelton water wheels. Water is supplied to the wheels through steel penstocks from Lake Buntzen, the north end of which is only 1,700 ft. from the power house. This end of the lake is the outlet end, and a concrete dam, 54 ft. high, was built across the creek, raising the level of the lake to 397 ft. above sea level, thus giving a mean head of about 390 ft. at the wheels. The penstocks are connected to steel pipes built in the dam at El. 378. These pipes are 4 ft. 6 in. in diameter, and the flow of water in the penstocks is controlled by roller-bearing sluice gates over the openings on the lake face of the dam. These gates are placed behind suitable racks and are operated from the crest of the dam. Ten openings for penstock connections were built in the dam to provide for future extensions of the power house.

Location Plan of Earth Dam and Rock Tunnels for Power Development.

Watershed.—The area of Lake Buntzen is about 500 acres, and this lake is used as a reservoir to supply water for the immediate needs at the power house. By the use of flash-boards across the spillway the lake level can be raised to El. 400, and it can be drawn down to El. 388 when it is so required, thus giving an immediate available supply of 6,000 acre ft. The Lake Buntzen watershed has an area of about 7 sq. miles, and the run-off is, therefore, light, excepting during the rainy seasons, when at times it reaches several thousand cubic feet per second. The main supply of water is drawn into Lake Buntzen from Coquitlam Lake through a tunnel connecting the two lakes.

The Coquitlam Tunnel is 12,650 ft. long, driven through the solid granite ledge separating the two lakes. It was designed for carrying 500 cu. ft. per second, but actual gaugings showed a flow of only slightly over 300 cu. ft. per second. The tunnel was unlined, and had a mean section area of 81 sq. ft.

Coquitlam Lake lies directly to the east of Lake Buntzen, and is separated from it by a ridge of mountains rising over 5,000 ft. above sea level. This lake is about 7 miles long, and has an average width of 2,500 ft., and an area of about 2,330 acres. The watershed area is 105 sq. miles. The original elevation of the lake surface was 432 ft. above sea level, but a rock-filled timber crib dam was built across the mouth of the Coquitlam River at the south end of the Lake, raising the lake surface to 443 ft. above sea level.

When the system was first put in operation in 1904, it was thought that ample provision had been made for any extension of the power house for some years to come, but the rapid development and growth of the country soon made it evident that the demand for power would, in a very few years, exceed the maximum capacity of the development.

After a careful investigation it was decided that the existing development could be enlarged to utilize almost the entire run-off of the Colquitlam watershed, at less expense, and in less time, than the development of a new water power project. It was, therefore, decided to increase the storage capacity of Coquitlam Lake by building a higher dam, enlarge the tunnel to obtain the required capacity, and install new generating units in the power house.

The precipitation over the Coquitlam watershed averages 156 in. per year. The winter snows are heavy and remain in the higher parts of the mountains until late in the summer, thus forming a splendid natural reservoir. The average run-off is very close to 1,000 cu. ft. per second, the co-efficient of run-off being between 75 and 80 per cent. There are short periods during the winter and summer months when the run-off drops considerably below the normal, but there are no extended dry periods such as is the case further inland.

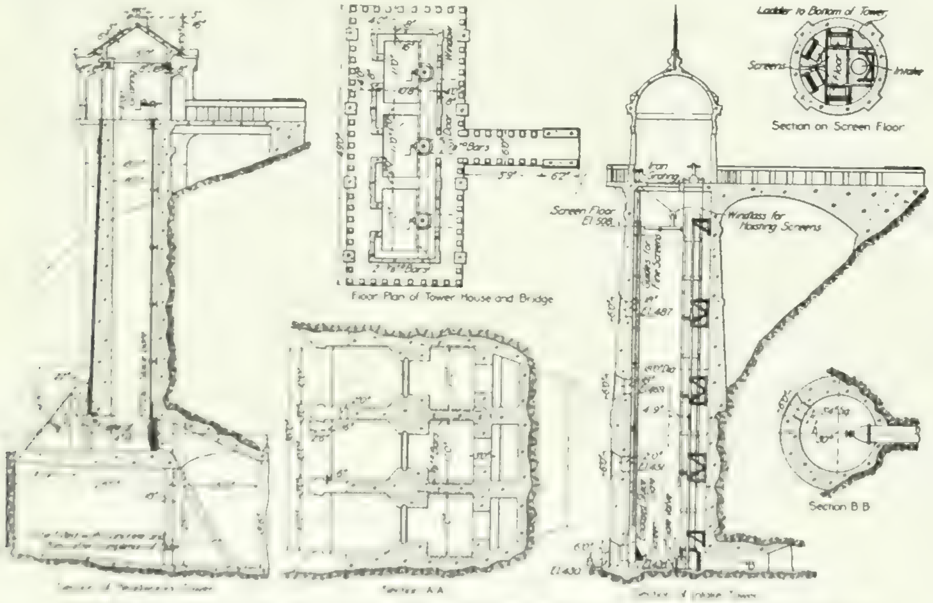
Coquitlam Dam.—In order to obtain sufficient reservoir capacity to store practically the entire Coquitlam run-off, it was decided to build a dam just below the existing timber crib dam, which would raise the lake level 60 ft. and increase the capacity of the reservoir by 162,000 acre ft. This will give a total available storage when the reservoir is full of nearly 175,600 acre ft., or 7,562,000,000 cu. ft.

The dam site is at the extreme southern end of the lake. On account of the geological formation, it was considered impracticable to build a masonry dam. Bed-rock lies so far below the surface of the valley that it would be impossible to get a rock foundation, and the hydraulic earth fill type was adopted on the recommendation of Mr. James D. Schuyler, M. Am. Soc. C.E., who acted as consulting engineer until all the original plans for the dam had been prepared.

The new dam is being built upon a great natural dam thrown across the valley at this point by the receding glacier, and is made up of fine blue glacial boulder clay, and tightly cemented gravel and boulders. Excellent construction material, in large quantities, is available and the borrow pits can be located in the most advantageous positions.

The city of New Westminster draws its water supply from Coquitlam Lake, and in order to safeguard its interests during the construction of the dam, and to approve of the final plans of the dam and the new waterworks intake, the Dominion Government appointed Mr. John R. Freeman, M. Am. Soc. C.E., to represent their interests under the agreement entered into between the Dominion Government and the Vancouver Power Company.

The completed dam will have a length on the crest of 850 ft. The crest is at El. 518, and has a width of 40 ft. The upstream slope is 5 to 1 from the crest to El. 467, and from there to the toe the slope is 1½ to 1. The downstream slope is 2 to 1 from the crest to El. 500, 3 to 1 from there to El. 475, where there is a berme 6 ft. wide, and from the berme to the toe the slope is 4 to 1. The extreme height of the crest above the lower toe is 98 ft. At both the upstream and downstream toes there are heavy rock walls, and these will confine and support the material sluiced into the dam. Both slopes are covered with riprap 3 ft. thick, the upstream riprap being laid in concrete up to above the normal water level. The total volume of the dam is 530,000 cu. yd., of which [illegible] cu. yd. are rock hauled in the toe walls and riprap and the remainder is sluiced material. There will be no core wall of any kind, and water tightness will be secured through the great thickness of puddle bound with several shallow trenches. The dam will be built almost entirely on tight blue glacial clay, which is quite impervious and forms a splendid foundation. The east end of the puddle keys into a deep trench made on the surface of the granite ledge which slopes at a steep angle towards the centre of the glacial valley.



Details of Gate Towers on the Coquitlam-Buntzen Hydro-Electric Project.

Spillway Section.—The spillway will be located at the east end of the dam, and will be cut through the spur of ledge so as to be entirely separate from the dam. The width of the cut at the entrance is [illegible] ft. and [illegible] ft. at the lower end in rock. The concrete sill of the spillway will be at El. [illegible], [illegible] ft. below the crest of the dam. A channel [illegible] ft. wide and [illegible] ft. deep will be cut along the west side of the spillway and will be used for the removal of logs and drift which may gather in the lake at the dam. This channel will be provided with a movable dam so that no water need be wasted unless required. The capacity of the spillway will be 12,000 cu. ft. per second when the water is 7 ft. deep over the sill. The spillway cut will necessitate the excavation of over 75,000 cu. yd., about 53,000 of which will be rock.

Outflow Tunnel.—During the construction of the dam the outflow from the lake will be carried around the dam site through a tunnel driven through the ledge under the spillway. This tunnel is 490 ft. in length, and has a sectional area of 400 sq. ft. The clear width is 26 ft., and the height is 18 ft. 6 in. to the centre of the roof, which is semicircular in form. The floor and sides, to a height of 12 ft., will be lined with concrete. The floor of the tunnel entrance is at El. 435, and slopes to 425 at the lower end. The tunnel was designed to carry 12,000 cu. ft. per second, when the lake surface is at El. 475, but will probably never be called on to carry much more than half of this, as the above quantity is the maximum recorded rate of run-off. After the completion of the dam, this tunnel will be used as an outlet or sluice tunnel.

The river is carried to the tunnel entrance in a channel 860 ft. long, tapping the lake at El. 443, immediately north of the old dam. This channel is 40 ft. wide at the bottom with sides sloping 1½ to 1, and calls for a total excavation of 202,000 cu. yd.

The channel at the lower end of the tunnel, carrying the river back to its old channel, is a much smaller piece of work, as the water can be depended upon to cut a channel for itself if it is properly guided and given a chance. The excavation for this channel amounts to 80,000 cu. yd.

Sluice Gates and Tower.—The gates for controlling the flow of water through the sluice tunnel will be placed in a concrete tower at the lake end of the tunnel. The floor of the tower will be at El. 455, spanning the tunnel entrance and supported on two piers placed parallel to the flow in the tunnel. Guides are provided at the upstream end of the piers for three gates, made up of 15-in. I-beams and heavy timbers, and these gates will be dropped into place when the dam is completed, thus closing the tunnel entrance. The space between the floor of the tower and the floor of the tunnel will then be filled with concrete and plums, permanently closing the upper end of the tunnel, excepting through the sluice gates. The tower is rectangular in form, built up of three separate compartments 8 by 11 ft., each one independent of the others. It is built back in the cut at the tunnel entrance, so that the back wall and side walls are against the rock for three-fourths of their height. The tower is surmounted by a concrete gate-house surrounded by a balcony at El. 513. A short concrete bridge connects the balcony with the shore of the lake. The main sluice gates are 5 ft. in diameter, and are placed in the back wall of the tower at the floor level, discharging directly into the tunnel. The openings in the front wall can be closed by auxiliary gates made up of I-beams and timber, and operated by chains from the gate house balcony. It is only intended to use these auxiliary gates for inspection of the main gates. Inclined racks are built against the front wall of the tower, protecting the gates from water-logged timber or other trash which might be drawn into the tower. Since the building of the dam and the consequent raising of the lake level rendered the New Westminster waterworks intake useless, it became necessary to construct an entirely new intake system. The new intake structure is a heavy concrete tower built on a spur of bedrock on the east side of the lake about 1,000 ft. north of the dam. The floor of the tower is at El. 428, and the floor of the concrete gate house at El. 518. The tower is circular in section, with an inside diameter of 18 ft., top and bottom. The walls are 4 ft. 6 in. thick from the bottom to El. 465, and taper to 18 in. at the top. A concrete arch bridge connects the tower with the shore. There are four 40-in. square intake openings in the tower placed at Els. 430, 451, 469 and 487, at angles of 60 deg. to each other. The openings are belled to the outside and covered with racks 6 ft. square. Gates are secured over the openings on the inside of the tower, and since these gates are subjected to back pressure only, tending to force the disc away from its seat, it was necessary to build them of special design. The cast steel gate disc slides in vertical guides, but the gate seat and the back of the gate are at a slight angle to the direction of travel. The disc is, therefore, wedged tight to the seats when in the lowest position, the guides taking the full thrust of the pressure of the water against the back of the disc. In all other positions of the disc the seats are not in contact; hook wedges are provided at the top and bottom of the gate to hold it against the seat. The seats, and all wearing surfaces, are lined with gun metal. These gates are enclosed in a sheet steel box having an opening directly in front of the gate opening over which the fine screens are placed. These screens are made up in teak wood frames and are lowered into position by means of a hand winch placed on the screen handling floor at El. 508. The screen frames slide in channel guides secured to the tower walls by brackets and anchor bolts.

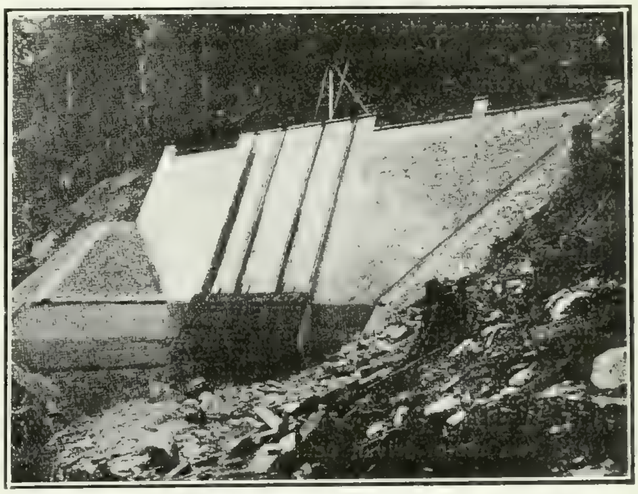
A secondary intake is placed entirely within the tower whereby the water may be drawn off at any desired level. This intake consists of a stand pipe 42 in. in diameter built up in four separate sections, each section having conical seats on the upper and lower ends, each section seating on the one next below it, and the bottom section seating on a heavy cast iron elbow set in the tower floor. The intake pipe sections are guided between two 60-lb. rails placed on opposite sides of the pipe and bracketed to the tower wall at frequent intervals. Lifting rods 1½ in. in diameter are attached diametrically opposite near the top of each pipe section. This intake is operated by hand by means of a lifting gear which may be attached to any set of lifting rods.

The openings in the intake pipe are at Els. 433, 451, 473 and 481. A channel 20 ft. wide at the bottom, with side slopes 1½ to 1, is cut from the base of the tower to deep water in the lake.

From the intake tower the water enters a tunnel 1938 ft. long around the east end of the dam, and connects to a distributing chamber near the lower toe of the dam. This chamber is supplied with a blow-off valve and pipe connections. The tunnel is all in rock excepting for a distance of 508 ft., which portion is lined with steel pipe 4 ft. in diameter encased in concrete. The tunnel in rock is 4 ft. wide by 6 ft. 6 in. high, and only the floor is lined with concrete.

Construction Methods, Excavation.—The construction of the Coquitlam dam was started in the winter of 1908. The whole of the dam site was covered with heavy virgin forest, and it was necessary to clear about 60 acres before other construction work was started. During the winter of 1909 the pumping plant was installed, and in the spring of 1910 the stripping of the dam foundations and the excavation of the diversion channel were started. All of this excavation work has been done by the hydraulic process and this method has proved very successful for the greater part. While working in the upper parts of the cut in the boulder clay banks, with a flume having a grade of over 3 per cent., as high as 11,000 cu. yd. of material were removed in one week, about 120 hours actual working time, using one jet delivering 10 cu. ft. per second at a pressure of 110 lb. per sq. in. at the nozzle. This record just cited is considerably above the average, but serves to show what can be done under proper working conditions.

In the excavation at the lower levels, a great deal of difficulty was experienced because of the very low flume grades and the heavy materials encountered. It became necessary when excavating the bottom of the diversion channel to use hydraulic gravel elevators to raise the sluiced materials from the floor of the channel to the flume level, a height of from 5 to 12 feet, depending on the distance the flume end extended into the cut. This flume was run on a grade of only 2½ per cent., and it was necessary to use great care in the grading of the sluiced materials so that they would not drag and clog the flume.



Completed Tunnel Intake, Showing Trash Rocks.

The flumes used in all of the excavation work are of rectangular section 20 in. wide. They are built of 1½-in lumber and are unlined on the sides. The bottom is lined with ¼-in. steel plates secured by countersunk screens and 2 x 4-in. strips nailed along the bottom corners. The lower end of each plate lapped over the one next below it about 3 in. This lining proved to be quite satisfactory, as the wear comes almost entirely on the bottom of the flume and the plates can easily be removed and replaced when worn out.

Practically all of the excavation was done in heavy boulder clay and in tightly cemented gravel and large boulders. The clay was easily handled, as it could be bored and shaken up with powder and then broken up and removed by the jet. The cemented gravel had to be treated quite differently, as it was almost impossible to bore and shoot it, and it would have required a very powerful steam shovel to handle it. It was found that a high pressure jet at close range made better progress than any other available method. Wherever it was possible to drill and shoot, this was done, but only shallow holes could be put down on account of the tendency of the drill to loosen the gravel and stick.

In these excavations a large quantity of boulders were uncovered which could not be run through the flumes. These were loaded into cars with a dragline bucket, with derricks or by hand, and dumped into the rock walls forming the toes of the dam.

The excavation for the New Westminster intake tower was made behind a cofferdam built out into the lake at that point. This dam consists of a timber crib filled with rocks and clay, having sheet piling driven along the face of the crib into the silt forming the lake bottom. The volume of this excavation was 10,000 cu. yd., 8,500 of which was sluiced and elevated from the pit by a hydraulic gravel elevator. The height of lift varied from 23 to 36 ft. At the greater lift, a 3½-in. stream under 125 lb. pressure was used in an elevator having a 10-in. throat. This method proved very satisfactory.

Tunnel Driving.—Both the sluice tunnel and the water supply tunnel were driven by contractors. Two shafts were sunk along the line of the water supply tunnel and it was worked from several faces. One of the shafts will be lined with concrete and used for inspecting the tunnel. The sluice tunnel was driven from the upper face and also both ways from a break-up directly over the point where it crosses over the water supply tunnel. This tunnel was driven with one heading and a bench. The heading included the whole tunnel above the springing line, 28 ft. wide on a 14-ft. radius, and the bench was 5 ft. deep. Most of the rock removed from the water supply tunnel was wasted, but all of that taken from the sluice tunnel was used in building up the toe walls of the dam.

The material overlying bedrock in the spillway cut was removed by the hydraulic process and the rock is being quarried out and placed in the dam toe walls by two cableways. The sluicing of material into the dam was started this summer. The borrow pits are placed in an advantageous position where the choice of material is large and the grades are good.

The original pumping plant supplying water for the sluicing operations consisted of two motor-driven centrifugal pumps of 4 cu. ft. per second capacity each, one of them operating against 50 lb. per square inch, and the other against 150 lb. per square inch. This plant has been increased by the addition of one motor-driven centrifugal pump delivering 4 cu. ft. per second against 150 lb. per square inch, and two motor-driven centrifugal pumps delivering 5 cu. ft. per second each against 150 lb. per square inch. The compressor plant consists of two motor-driven compressors delivering 400 cu. ft. per minute at 100 lb.

Power is obtained from the Lake Buntzen power house. The line supplying the dam taps the company's line six miles south of the dam site. The current is transmitted at 34,000 volts and transformed at the dam site to 2,200 volts, [illegible]

Enlargement of Coquitlam Tunnel.—It was absolutely [illegible] Coquitlam Tunnel open for a large part of the time in order to maintain a supply of water in Lake Buntzen, and this made the actual working time in the tunnel very uncertain and of short duration. During the summer months more than half the time was lost in this way on [illegible] from the Lake Buntzen [illegible]

The work of enlarging the tunnel was started from the [illegible]

[illegible] engineers was the "overhead" method, which consisted of [illegible] tunnel sides. These timbers were placed about 6 ft. apart, [illegible] timber floor as the floor of the heading. In this way the work could be carried on in both directions from as many "break-ups" as was practicable. The several headings were mucked into cars on the track in the tunnel below by withdrawing the floor timbers and opening up the floor directly in front of the muck pile. The timbering was kept well ahead of the faces and left standing for some distance behind them. During the first part of this work horizontal holes about 6 ft. deep were drilled into the face of the heading in the usual way, but on account of the hardness of the rock and the heavy charges of powder necessary to make a clean break it was almost impossible to make the timbering of sufficient strength to stand the blow. The method of drilling was, therefore, changed and vertical holes were drilled from the tunnel below before the timbering was put in, keeping the drilling well in advance of the face. This system of drilling and shooting proved satisfactory, as the force of the shot did not act downward on the timbers, but threw the muck back from the face.

This method of enlargement gave the tunnel a section much the same as an egg held with the point down, with an area of 176 sq. ft.

Some very fair work was done under this system after the crew was well broken in, but there was one difficulty which it seemed impossible to overcome. The timbering cut down the area of the tunnel to such an extent that its capacity was considerably decreased. This made it necessary to leave the tunnel open for a greater part of the time than would have been necessary otherwise, in order to keep the level of the water in Lake Buntzen above the lower limit, and, therefore, less time was available for work in the tunnel. The greater the number of headings worked the greater was the obstruction in the tunnel, as timbering was necessary at every heading. The demand for water was increasing daily in spite of the fact that the company had built a steam plant in the city and had relieved the Lake Buntzen power house of 4,000 kilowatts of its load.

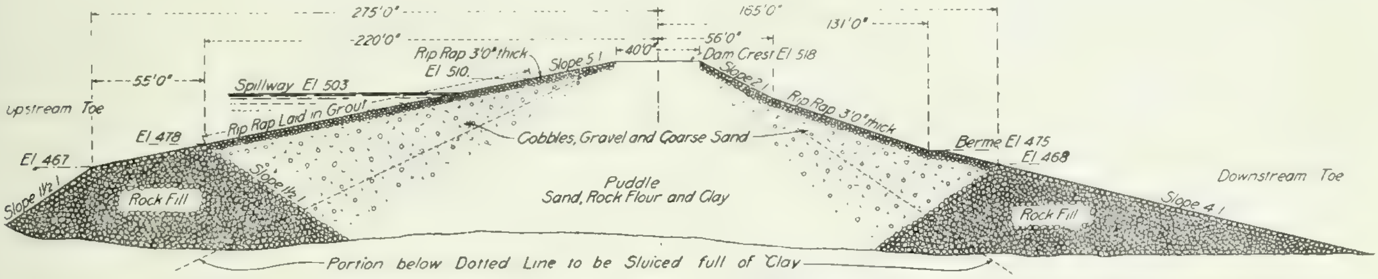
In July of 1910 the "overhead" method was abandoned in favor of one which necessitated no timbering. At this time about 1,800 ft. of enlargement had been completed and the tunnel was drilled to a point 3,000 ft. from the portal. Before changing over the drilled portion was completed by the first method.

Drilling and Mucking.—The method by which the remainder of the tunnel was enlarged consisted of removing sufficient rock from one side and the roof to increase the area from the original 81 sq. ft. to 192 sq. ft. The side headings were started at intervals of from 100 to 130 ft., and were worked in both directions. The drilling was all done from the main tunnel at right angles to the line of the tunnel. The holes were drilled 8 ft. deep, and were placed in vertical rows spaced 3 ft. apart, each row having five holes. Two rows of holes were drilled from one setting of the drill column mounting two drills on horizontal arms, one on each side of the column. The drilling was carried on independently of the shooting and mucking, and was kept well ahead of these two operations. When the "break-outs" were first started and were narrow between the faces, only one row of holes would be shot on each face, but two rows were shot on each face after the headings had widened out sufficiently to accommodate the muck pile without spilling it out over the tracks in the old tunnel. As many as 14 "break-outs" were worked at one time, giving 28 working faces. This operation removed the rock from the side of the tunnel, and the roof was trimmed up by a separate gang following the first. The heavy shots in the side of the tunnel broke out well into the middle of the roof, and it was often necessary to do very little trimming. After the side holes had been shot and mucked a small, gang followed with stoping drills and drilled the roof where it was necessary.

The work was carried on in the tunnel as long as the water in Lake Buntzen was above the minimum level. When this level was reached the tunnel was opened and allowed to remain open until the lake was filled again. Two ten-hour shifts were worked in the tunnel. All of the drilling was done on the day shift, and the shooting was done when the drilling shift went off duty.

When the night crew came on the two tunnel locomotives took the men as far as the first face, where they started to clear the track of all muck. As soon as the track was cleared the cars were spotted at each of the faces and the mucking was carried on as quickly as possible and the tunnel cleared ready for the day shift and drills.

The muck was hauled in 1⅓-cu. yd. side dump cars, which were handled in the tunnel in trains of 25 to 30 cars by electric locomotives of 40 h.p., taking current at 500 volts from a trolley wire hung from the roof of the enlarged tunnel. The trains were run on schedule time, having regular passing points. There was also a telephone in the tunnel, and any delay was reported and the passing points of the trains changed accordingly. Side tracks 500 ft. long, for the passing of trains and the storage of cars, were built in the enlarged tunnel every 1,000 to 1,200 ft. The track was laid on 36-in. gauge and constructed of 20-lb. rail. Two lighter locomotives were used for handling the cars outside of the tunnel on the dump and making up trains for the tunnel locomotives.



Cross Section of Dam, Showing Distribution of Material.

The muck was all dumped into Lake Buntzen, which is very deep at the tunnel entrance. The dumping tracks extended down the shore from the tunnel for a distance of about 1,000 ft. On account of the tendency of the dump to slide under the weight of the loaded cars, it was carried out on two levels and the tracks were kept some distance apart. By this arrangement the cars could be dumped from the upper track while repairs were being made, or the track shifted on the lower dump.

Drainage and Ventilation.—When the gates at the Coquitlam end of the tunnel were closed it was necessary to wait for some time before the tunnel was sufficiently free of water to allow the workmen to enter. In order to better this condition, an automatic shutter dam was placed in the tunnel at station 72 + 00. This dam was pivoted on its horizontal axis and closed automatically when the water was 4 ft. deep, thus storing the water to that depth behind the dam, allowing the lower end of the tunnel to clear quickly. When the gates were again opened and the water raised, the dam swung so as to be parallel to the flow of water, offering no resistance to the flow.

The original tunnel was not driven straight through on one grade, but sloped from El. 400 at the Buntzen portal to El. 410 at station 72 + 00. From there it sloped to El. 407 at station 119 + 00 and to El. 428 at the Coquitlam end at station 126 + 45. There therefore existed a sump nearly 5,000 ft. long near the Coquitlam end of the tunnel, where the maximum depth of water was about 4 ft. It was at first intended to enlarge this portion by shooting down enough rock from the roof of the tunnel to fill the sump and bring the floor to true grade, thus having a dry tunnel to work in, but this plan was rejected in favor of placing a large motor-driven centrifugal pump at the Coquitlam end of the sump and pumping the water from the sump back into Coquitlam Lake. The pump was set up in a water-tight compartment blasted out of the side of the tunnel. The pump motor was started from above shortly after the gates were closed and the sump pumped dry in a very short time. The method of enlarging the tunnel from the summit, through the sump, and to the gates at the Coquitlam end, was the same as that used up to the summit.

The tunnel being open at both ends, it was a comparatively easy matter to ventilate and clear out the powder gases. A large motor-driven blower of 56,000 cu. ft. per minute capacity was placed at the Buntzen portal. After the shooting was done the portal was closed and the blower started, and all gases were cleared out within 30 minutes.

Drills and Drilling Gangs.—No. 7 Water Leyner drills were used almost exclusively in the work of enlargement, and the work done by these machines is exceedingly creditable. They averaged something over 40 ft. of hole per machine per day of less than 9 hours actual drilling time. most of the machine men were not experienced Leyner men, and they were often prejudiced against that drill, but they learned rapidly and soon came to like the machines. The greatest number of drills in use in the tunnel at one time was 54, not counting the stopers, which numbered from 3 to 7.

Each drilling foreman had charge of four machine crews. Upon going off shift, the drill foreman loaded all of his machines and steel on the train and took it to the repair shop, where the machines were gone over by the repair crew during the night, and any necessary adjustments were made. In this way the machines were always kept in first-class order. On going into the tunnel each morning each drill crew attended to the loading of their machines and sharp steel. One repair man was kept in the tunnel on the drilling shift and any slight repair or adjustment could be made at once. The steel sharpening was done by three Leyner sharpeners working two shifts of ten hours. One temperer on each shift tempered all the steel.

Air was furnished to the drills by two compressor plants, one at each end of the tunnel. The Buntzen plant consisted of one Ingersoll-Rand and four Leyner motor-driven compressors having a total capacity of 2,250 cu. ft. of free air per minute. The Coquitlam plant consisted of two Ingersoll-Rand motor-driven compressors having a capacity of 500 cu. ft. of free air per minute. Both of these plants fed into a 5-in. diameter air main running the whole length of the tunnel. Water under pressure was furnished to the drills through a water main laid parallel to the air main.

The tunnel enlargement was completed in March, 1911, in less than 100 working days after the side method of enlargement was started. The average advance per day of two shifts during this time was very close to 100 ft. of enlargement. The maximum advance for one day was 175 ft., when 730 cars of muck were hauled out of the tunnel. The maximum number of men at work at one time was 450. Serious accidents to the workmen were very rare occurrences. On most work of this character accidents are almost the rule, but on this work only one man was killed by rock falling from the tunnel roof, and two were injured by a "missed hole."

Tunnel Intake.—When the tunnel enlargement was started a 9-ft. diameter Coffin sluice valve was put in the tunnel a short distance downstream from the old gates. This valve was placed in the tunnel at the bottom of a shaft sunk from a tunnel which was driven above the proposed high-water level of Coquitlam Lake and was designed to operate under 85 ft. of head.

When the tunnel enlargement was completed the Coffin gate was taken out and re-set about 40 ft. upstream in place of one of the original sets of gates, and the old gates were removed entirely. In the place of the Coffin gate two Stoney roller bearing sluice gates were installed. These gates are each 4 ft. 6 in. wide and 10 ft. high. The Coffin gate is set in a Venturi throat and the tunnel is concrete lined between the Coffin and the Stoney gates. The Stoney gates will be used as the usual operating gates, and the Coffin gate as an emergency gate or whenever perfect watertightness is required.

The original intake consisted of a rock-filled timber crib built out into the lake and enclosing three intake tunnels 7 ft. square, made up of 12 x 12-in. timbers set close. These short intake tunnels were joined together into one tunnel back in the rock in front of the gates. The capacity of this intake was not sufficient for the enlarged tunnel and it was therefore torn out and a new one constructed.

The new intake consists of a heavy masonry retaining wall inclined back against the steep hill above the tunnel entrance, the elevation of the top of the wall being above the proposed high water level. The bottom of the wall is on bed rock and it is 50 ft. wide at the tunnel entrance. The main wall is flanked by two inclined wing walls extending diagonally out into the lake from the back wall. Four rails are laid vertically up the face of the back wall from below the tunnel entrance to the top of the wall, and these rails form the track to the racks. The racks are mounted on eight wheels and are made up of a heavy framework of I-beams supporting a "gridiron" of 40-lb. rails laid vertically a few inches apart. The gate operating gear is placed in the upper tunnel and the gates are geared to be operated by either electric motor or gasoline engine, or they can be operated by hand.

The rack is 41 ft. wide and 35 ft. high, and is supported by heavy cables, counterbalanced that it can be raised and and cleaned at any time, and operated by a power winch. In case any very heavy drift gathers in the forebay it can be removed by a heavy [illegible] [illegible] which is placed on the top of the retaining wall.

Power House.—Since the original installation of four [illegible]-kw. generators in the Lake Buntzen power house the capacity of this plant has been increased three times, each time by the addition of one [illegible]-kw. generator driven by [illegible]-h.p. impulse waterwheel. The present capacity of the plant is [illegible] kw. in [illegible] generators driven by waterwheels totaling [illegible] h.p. Three-phase, [illegible] current is generated at [illegible] volts. Two [illegible] waterwheel and motor-driven exciters supply the excitation current for the main generators. The equipment is complete with all switchboard instruments, etc., but the transformers and high tension apparatus are placed in a separate building. The power house is a native granite building and the transformer house is constructed of reinforced concrete. The current is stepped up in the main transformers to 34,000 volts, at which voltage it is transmitted to the various sub-stations around Vancouver.

No further extension can be made to this plant without going to great expense, and the company now has under construction a separate power house at a point about 1,800 ft. south of No. 1 plant.

This new power house, known as "Lake Buntzen Power House No. 2," will draw water from Lake Buntzen through a concrete-lined tunnel 14 ft. 8 in. in diameter and 1,750 ft. long. A concrete surge tank is built at the lower end of the tunnel, and the water is conveyed from the tank to the power house, a distance of 600 ft. down the hill, through three heavy steel penstocks 8 ft. 6 in. in diameter.

Power House No. 2 will be equipped with three generators of 8,900 kw. capacity driven by 13,500-h.p. Doble impulse wheels. Each generating unit is complete with a 300-kw. waterwheel and motor-driven exciter. Three-phase, 60-cycle current is generated at 2,200 volts and stepped up to 60,000 volts in the main transformers, at which voltage it is transmitted to Vancouver. The equipment of this power house will be complete in every way and of the most modern and approved design, and will include 36,000 kw. in transformers, together with all high tension switching apparatus. The power house building is of reinforced concrete and of handsome design. Two of the three units will be installed and put in operation during the winter of 1912-13.

The works at present in progress are being carried out under the direction of Mr. R. H. Sperling, general manager, and Mr. G. R. G. Conway, chief engineer of the company, assisted by Mr. W. V. Hunt, hydro-electric engineer; Mr. Fleming Ramsaur, resident engineer at Coquitlam Dam, and the writer as assistant engineer. Mr. J. R. Freeman, M. Am. Soc. C.E., is advising engineer for the Dominion Government, and Mr. R. S. Stronach is inspecting engineer, acting under instructions from the Water Powers Branch of the Department of the Interior.

◆

A NEW BRITISH FACTORY FOR DIESEL ENGINES.

In spite of the progress which has been made by Continental engineers in the construction of Diesel engines it is of considerable interest to note that extensive Diesel engine works are being built as Ipswich by the Consolidated Diesel Engine Manufacturers, Limited, London. This will be the first large factory in Great Britain devoted exclusively to the manufacture of Diesel engines for ship propulsion as well as for stationary purposes.

Situated in a most convenient and accessible quarter of the town, with lines from the Great Eastern Railway running direct into the buildings, the new works will be equipped completely with the latest types of machinery and plant for first-rate workmanship. From the inauguration employment will be given to several hundred workmen, and provision has also been made to secure additional land in order to cope with the increasing demand for Diesel engines. All preparations are well in hand, and it is anticipated that the works will be in full swing in the early part of the coming year.

Mr. W. J. [illegible], managing director of the Consolidated Diesel Engine Manufacturers, Limited, is in Toronto this week and expects to go on the Coast before returning to England.

CITY GOVERNMENT BY COMMISSION.

The justification for government by city council will fast disappear if many men of the type indicated by the following statement are elected municipal office. An alderman in one of our larger cities the other day made the statement that the day should never come again when the judgment of experts should be considered infallible, especially when the expenditure of immense amounts of money is involved. To secure economy in carrying on the industrial affairs of a city the work necessarily must be in the hands of experts. Until this fact is thoroughly understood by the public, inefficiency and waste must follow the present system. Prof. Slichter, of the University of Wisconsin, in a recent address on the present tendencies of this age, states that perhaps the greatest mission of science and industrialism to our era is the removal of controversy from human progress. This is, indeed, a great service to mankind—to narrow the field of strife, to remove obstacles, to settle great public matters by bringing to bear accurate data, adequate analysis of cause and effect, and expert judgment—so that contention, or partisanship, or politics, is eliminated, and things are settled on their merits. This phase of the industrial age is fast developing. The numerous expert commissions appointed by the States and Government to investigate and determine important questions upon the basis of exact knowledge is a pertinent illustration. The Wisconsin Commission is settling all matters concerning the public utilities solely after adequate investigation and skilled tests. These same matters can never again become the football of partisanship or political manipulation. Likewise, the commission form of municipal government is removing from the field of politics, and local contention, questions which are really largely matters of skill and exact science. The best kind of water supply, the proper sort of sewage disposal, the best way to handle streets, street railways, public parks, schools, playgrounds, public health, the housing problem, etc., are no longer matters of fight or ballot in well-ordered communities. There exists always a best way, and experts are selected to find and direct it. The modern civilized community is no longer a state, but a school. The body politic has become one vast, complexly organized, research institution. Governments are, in this age of industrialism, instruments for replacing darkness with light, for substituting for the indefinite and approximate, the definite and accurate. This is about all there is to the best public service. The State has become a great thinking, investigating organization, or laboratory, or research institution. There is this distinction between the school and the State: the school researches only, the State researches and acts. The illumination of great public matters by modern scholarship is best illustrated by what is constantly occurring in the countries of western Europe. There, as every one knows, municipalities are in the hands of experts whose life work is a study, as in a laboratory, of the needs of the community and its individuals. Nothing is left to chance, and little to choice, except when the people can be trusted to choose wisely. The city and State with its utilities, sanitary inspection, land purchase, construction and sale of homes for working men, control of food, care of children, supply of milk, expert advice to mothers, the promotion of all sorts of special schools, museums, galleries, theatres, concert halls, municipal banks, pawnshops, employment bureaus, industrial insurance, old-age pensions, etc., etc., is conducting a laboratory for racial and civic betterment, and is carrying upon the broad shoulders of the State the burden that a democracy would shift to the people themselves. All new or difficult questions receive special study, and an honest attempt is made to settle them in the best manner.

◆

SEWAGE DISPOSAL AND THE GREAT LAKES.

The International Joint Commission on Waterways is now in session at Ottawa, and is taking evidence preparatory to reporting on the question of the pollution of boundary waters. It will be remembered that a short time ago this Commission was instructed by the governments of Canada and the United States to investigate and report on this question.

Dr. McLaughlin, of the Surgeon-General's Office at Washington, D.C., in his evidence before the Commission last week, stated that to compel cities along the Great Lakes to so treat their sewage that it would not contaminate the lakes into which it is dumped would place upon these cities an unnecessary and unjustifiable expense which would bankrupt the cities in most cases. He adds that it is largely a matter of sentiment which would prohibit dumping raw sewage into rivers and lakes. He considered it impossible that contamination from Canadian cities was ever washed across the lakes to make impure the water of an American city, or vice versa.

Dr. Hastings, Medical Health Officer of Toronto, takes issue very strongly with Dr. McLaughlin, and his objections are well taken. Dr. Hastings, however, labors under a misapprehension when he states that Dr. McLaughlin's viewpoint, as expressed in his evidence, is that of the engineer rather than the health officer. It is true that the engineer is controlled to some extent from the standpoint of economy, and is not governed by the desire for complete bacterial purification. Dr. McLaughlin cannot be considered in any sense an engineer, and we are quite satisfied that if engineering experts had been consulted their evidence would have been very different from his.

If Dr. McLaughlin has been correctly quoted, his evidence is certainly not borne out by the facts. It is well known that Niagara Falls, for many years, has had the highest death rate due to typhoid of any city or town in America, and this has been directly due to Buffalo dumping its untreated sewage into the Niagara River above Niagara Falls. The provincial bacteriologist for Ontario in his report for last year states that a study of Lake Ontario water would lead one to suspect that this lake is becoming more and more infected. The samples collected some years ago would have led one to hope that it was possible to go out into the lake far enough to escape the infection, but this year he has found infected samples and those containing high bacterial counts fifteen miles out into the lake. The chemical samples collected at the same time bore out these findings. He states that though infection is less frequent far out, still it exists, and comparatively frequently.

It is understood that the provincial health authorities of Ontario will be represented before the International Joint Commission before the investigation is completed, and it is altogether probable that their evidence will be decidedly against that offered by Dr. McLaughlin.

EDITORIAL COMMENT.

It is nearly time the city of Toronto took action on the question of a City Architect. We are tempted to believe that another of the Council desires a permanent civic position.

* * * *

The council of the city of Winnipeg, as is usual with such bodies, before acting on the report on a new water supply, is first wasting valuable time in criticism of the expert who made the report. What should be done at the earliest possible moment is to secure an accurate estimate of the cost of obtaining water from Shoal Lake.

* * * *

The raising of the standard of entrance to the University of Toronto this session has had its effect on attendance. Last year's registration in the first year of the Faculty of Applied Science and Engineering was about two hundred and eighty. This year's registration is, to date, one hundred and eighteen.

* * * *

Hon. Frank Cochrane, Minister of Railways, at a railway route map hearing, held in Ottawa recently, withheld his approval of the route of the Alberta, Peace River and Eastern Railway until October 15th, in order to give the promoters an opportunity to prepare a map of the Calgary-Edmonton section, giving more details and indicating more clearly the location of the other railway lines. Incidentally, he stated that in future he does not propose to approve railway lines until good surveys have been made. We are glad to note this move of the Minister. Far too many projected railroads have received their charters without sufficient preliminary surveys being made to show the practicability of the individual schemes.

* * * *

Last week we emphasized the remarks of Sir William Willcocks before the Western Canada Irrigation Association, concerning the tendency towards light design in the irrigation works of Western Canada. In the daily press this week we note that the intake belonging to one of the irrigation companies has failed. The structure is almost completely destroyed, and it is understood that there was the loss of one life. There is little question that in many instances economy of design rules to the exclusion of a proper factor of safety. The regulating works on the rivers in the East are most conservatively designed and built; in fact, to the minds of those in the West, accustomed to making a dollar go as far as it will, these works appear stronger than there is any necessity for. At the same time, practically no failures occur there. As population increases in Western Canada, the necessity for more permanent works will become apparent.

◆

DEATHS IN FACTORIES.

According to the report of the chief inspector of factories of Ontario for the year ending December 31, 1911, there were [illegible] accidents reported during the year, which is an increase over the previous year. One reason for the increase is that minor accidents are now reported and another is that the law regarding the reporting of accidents is better observed than formerly. The chief inspector states that a large percentage of the accidents were due to causes that could not reasonably be removed and could only be avoided by the exercise of care on the part of the employees themselves. The fatal accidents totalled 44, which was proportionately the same number as in 1910.

CANADIAN PORTS OF THE PACIFIC.

The Panama Canal is now so nearly an accomplished fact that the importance of the Canadian ports on the Pacific is becoming greater than ever. In a paper prepared for presentation to the annual convention of the American Society of Civil Engineers to be held at Seattle, Wash., on November 20th, 1912, Mr. H. M. Chittenden has discussed the larger ports of the Pacific Coast under the headings of Strategic Relations of Coast Ports, Descriptive Data, Engineering Problems, Administrative Systems, Plans for the Future, Influence of the Panama Canal. As the paper is a very comprehensive one and rather long, we present a very brief abstract of that portion which deals with the Canadian ports.

Commerce of the Pacific.—Since the days of Magellan, imaginative minds have pictured the Pacific Ocean as the future home of the world's commerce. There is something in the immensity of that ocean, in the present vastness of the population on one shore and the future vastness of that on the other, which conjures up visions of argosies such as the Mediterranean or the Atlantic has never known. The situation as it actually exists, however, makes this picture somewhat of an illusion. The very wideness of the intervening sea is a mighty barrier to economic intercourse across it. The breadth of the Pacific as compared with that of the Atlantic, depending on the latitude, is as two or three to one; and, while the cost of transit and loss of time may not be in the same proportion, there is still a wide disparity against the larger ocean. There are also the almost insuperable barriers of race and economic conditions on the Asiatic Coast. We do not admit the Oriental to our shores as we do the European. That immense source of traffic which has sustained its thousands of ships on the Atlantic is cut off on the Pacific. Likewise those Oriental countries have little to offer the traveller, which can compare with the lure of European civilization, ancient and modern. Tourist traffic across the Pacific is a bagatelle compared to that over the Atlantic. Finally, the deep poverty of the hordes who swarm the Asiatic shores, and the backward condition of industry there, are not promotive of vigorous commercial intercourse, for they offer relatively little to sell and less with which to buy.

Thus it results that the commerce of this ocean, great though it be, is small compared with that of the Atlantic, and small to what might be expected from the millions of inhabitants affected by it. Its growth in the near future, strange as it may appear, is more dependent on the countries which border the Atlantic than on those washed by its own waters. As far as the Pacific Coast is concerned, the eyes of its people are turned east rather than west. It is there that their kindred dwell; it is there that the capital exists which shall develop their boundless resources; it is thence that must come those who shall help to populate their shores. It is this fact—that their future is on the Atlantic rather than on the Pacific—which makes the opening of the Panama Canal an event of such tremendous import to them. It is bringing them to their own. It fronts them toward Europe. It opens to them the treasures of the Occident—far more potent, if less romantic, than those of the Orient. It gives them something of the advantage which the eastern shore of the Continent enjoys by reason of its closer relation to the fundamental sources of our civilization.

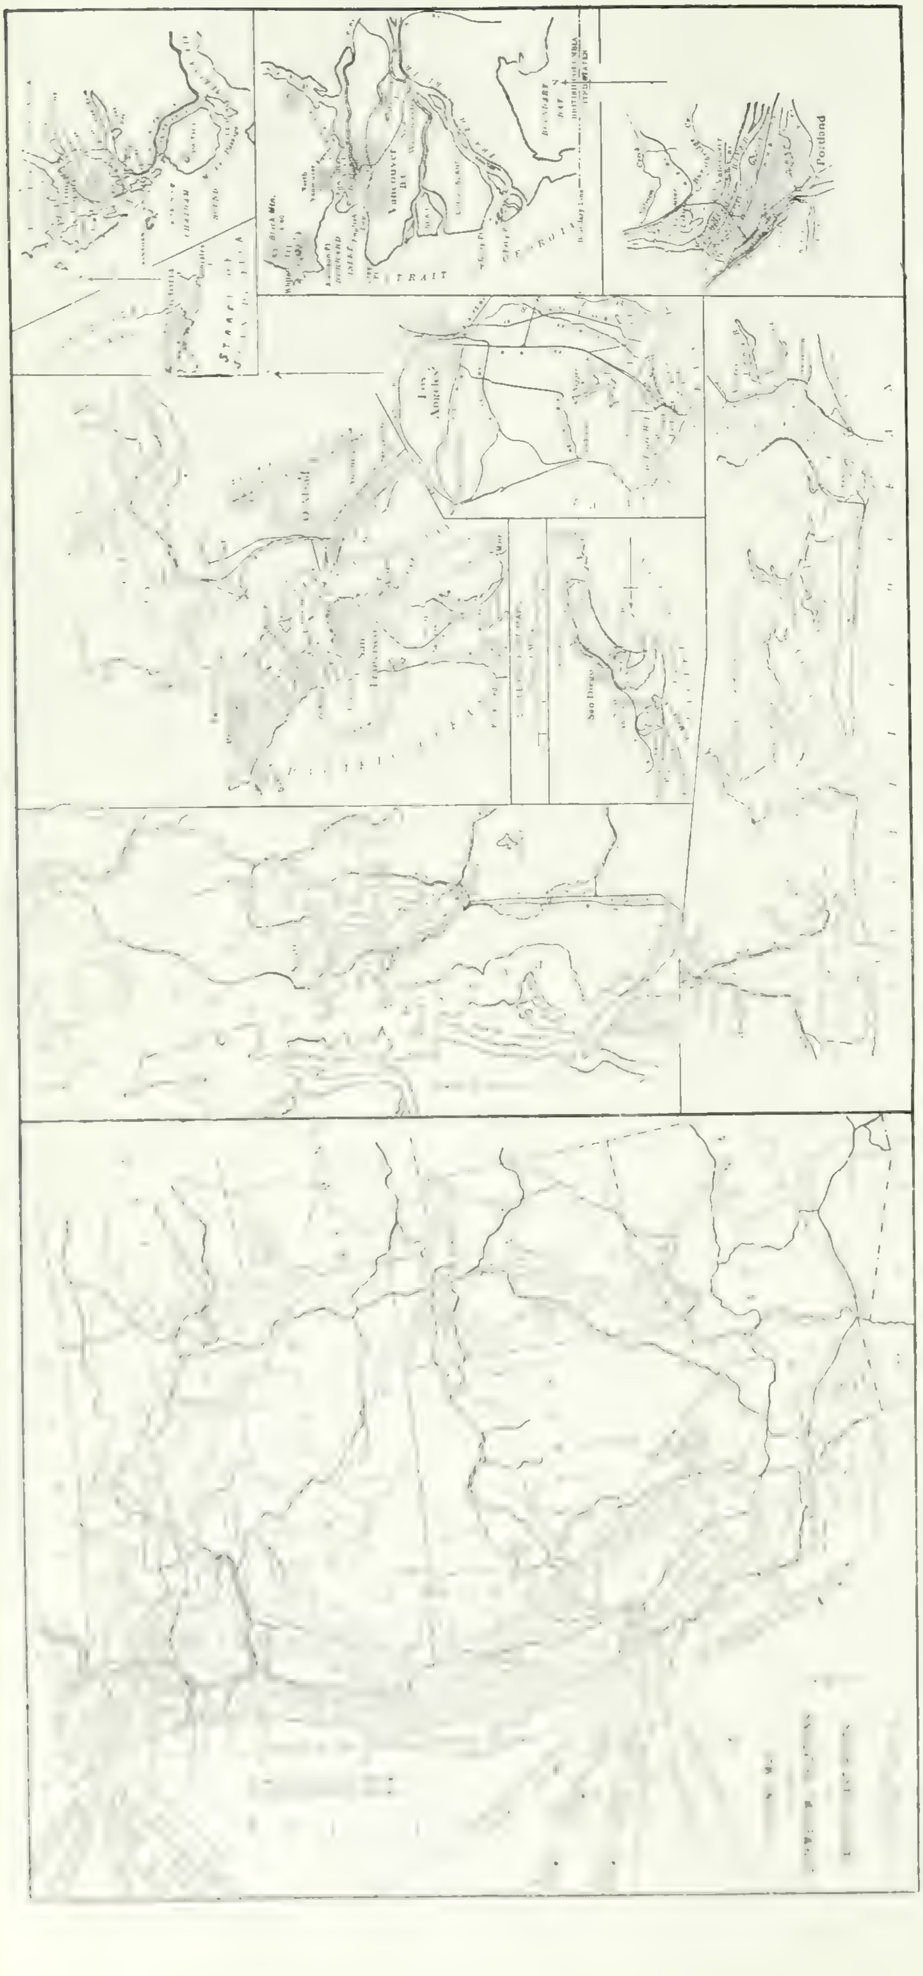
If this condition is true of the present, and will remain so, to a degree, for the indefinite future, let it not blind us to the profound changes which are taking place in those ancient, and, but yesterday, non-progressive, countries which lie on the other side of the Pacific. When we consider what a volume of commerce the accidents of political fortune have turned in this direction from the [illegible] Philippines, when we reflect on the marvellous progress of modern Japan; and when we note the amazing changes now going on in that venerable nation which has slumbered indifferent to the rest of the world for thirty centuries or more, we cannot afford to take a pessimistic view of our future relations with that side of the globe. If ever these people accomplish what is within their practical reach; if ever they turn to account, as is done in Europe and America, their wealth of natural resources and their own capacity for industrial development, surely there will result a mighty increase in trade between them and the rest of the world, and of this the American Continent will enjoy the greater share.

Thus, while the Atlantic holds out to us the brighter present prospect, there is brilliant promise in the Pacific, and in every direction the future is big with hope. Visions of the coming day are profoundly stirring the minds of men. Expansion is in the air. The measureless force of unseen psychological influences rushes the world along whether it will or no. Doubtless, it builds exaggerated hopes and paves the way to much disappointment, but its very exuberance of faith is an earnest of vast accomplishment.

This far-reaching movement, which has been crystallized into definite form by the approaching consummation of the greatest engineering work of ages, finds its intensest expression along the Pacific Coast of North America. To other parts of the world, the Panama Canal means simply increased opportunities for trade; to the Pacific Coast it means a new lease of life through the elimination of those barriers which separate it from its true source of sustenance and growth. Everywhere along the Coast, faith in the beneficial results of this great work is unbounded. It is a faith, moreover, which expresses itself in works. From Alaska to Lower California, the Coast is getting ready for the Canal. It is putting its house in order. It is spending in this work prodigious sums of money. The present decade will witness an expenditure in port development of probably $50,000,000. The slogan which has won this vast sum from the pockets of the taxpayers is: "Get ready for the opening of the Panama Canal," and the formal celebration of that event will find the work well toward completion.

It would be idle to pretend that this prodigious effort springs solely from an actual necessity of providing for the increase of traffic that will result from the opening of the Canal. The popular belief is, of course, that this is the case; but those who have studied the situation closely know better. They realize that the movement is being overdone, but they recognize that it is bound to keep on through the fear which each port entertains of what its sister ports may do. The stigma of possible failure in the race and fear of loss of prestige are the potent forces which are back of these extraordinary efforts. Los Angeles or Seattle would find it difficult on the cold basis of rational business foresight to justify their enormous prospective outlays; but they find ample justification in the necessity of keeping up with a procession which now stalks with tremendous strides from one end of the Coast to the other.

Vancouver, B.C.—Seattle's greatest rival for commercial supremacy north of Portland and Tacoma is Vancouver, B.C., a rival whose strength lies not so much in its natural advantages as in the artificial conditions arising from its being in a different national jurisdiction. It has a good strategic location, it is true, being at the outlet of the second greatest river of the Pacific Coast; but its harbor is inferior to those farther south, and its rail connections east, even to Central Canada, are inferior. Its early growth was due primarily to the fact that it was a Canadian port. That the port would have developed where, or as rapidly as, it has, if there had been no international boundary near by may well be doubted. As conditions actually exist, however, taken with the present status of American navigation laws by which



cheaper foreign shipping is excluded from our coastwise trade, Vancouver is a formidable competitor with ports farther south. In the fish and lumber export trade, particularly, conditions tell heavily in her favor.

Prince Rupert.—Prince Rupert is the northernmost Pacific terminus of the transcontinental lines and will remain so until some line shall cross into the valley of the Yukon and descend that mighty river on its way to the westernmost apex of the Continent. It is 40 miles south of the international boundary of Alaska (54° 40′) and about 700 miles along the coast from Seattle and that much nearer Alaska. It is the westernmost, as well as the northernmost, transcontinental terminus, and is 500 miles (according to the statement of the Grand Trunk Pacific officials) nearer Asia than any other terminus on the Pacific. It is said that a traveller from China would be able to reach Winnipeg, via Prince Rupert, before he could reach Vancouver, if he were to go by that port. Add to this the fact that the gradient over the mountains, with the exception of about 20 miles of 1% on the west slope, is everywhere under five-tenths, and most of the way much less than this, and some of the physical advantages of the route are apparent. Add again the proximity of Prince Rupert to the limitless wheat fields of Canada, the fact that it is in the very centre of the salmon and whale industry, among inestimable quantities of virgin timber, and its great future seems doubly assured.

Its advantages are offset to some extent by the severity of northern winters, but chiefly by the different nationality of the territory (Alaska) which it is best fitted to serve.

Secondary Ports.—Somewhat outside the rivalries of the great ports along the Coast, and flourishing on advantages which are peculiar to themselves, are several smaller ports. Among them, and the more prominent, are San Luis Obispo, about half way between San Francisco and Los Angeles; Humboldt Bay, on the North California Coast; Coos Bay, [illegible] miles south of the Columbia, and serving an important section of Western Oregon; Astoria, just inside the Columbia Bar and the first port to be established on the North Pacific Coast; Grays Harbor, a great lumber port on the west coast of Washington, [illegible] miles north of the Columbia; and Victoria, an important harbor and naval base on Vancouver Island. There are numerous harbors on the Alaskan coast, but they are still in a state of Nature. [illegible] yet has been done toward converting them into up-to-date ports. The prospective opening of the coal fields of Alaska, and a more definite Alaskan policy on the part of the Government, will undoubtedly lead to the establishment of permanent facilities at some of these points in the near future.

In its physical characteristics the Pacific Coast line of North America increases in severity from south to north, but there is less diversity in climatic conditions than one might expect for such great differences in latitude, owing to the moderating effect of the ocean currents. It is not until well up on the Alaskan Coast than one finds the harbors regularly sealed by ice in the winter season. Storms are more severe in the northern latitudes, but this is more than offset, as far as coastwise trade is concerned, by the sheltered inland passages which extend for at least 1,000 miles from Southern Puget Sound north. The tidal fluctuation increases from south to north from a mean of about 4 ft. at San Diego to 14 ft. at Prince Rupert. The teredo is very destructive in all the waters of the Coast, but the limnoria is active only in Californian waters. Nearly all the tributary streams are heavy silt carriers, and the primeval bays and inlets are partly or wholly filled up, making dredging a necessary adjunct of harbor development all along the Coast, and necessitating costly training dikes to scour channels across bars or shoals. In Southern California, the immediate shores were originally lightly timbered; but from Northern California north they were covered with magnificent forests. The coast line is remarkably uniform and unbroken by indentations as far as the Strait of Juan de Fuca, but from there north the exact opposite is the case.

Vancouver, B.C.—The chief Canadian port, Vancouver, B.C., is in the vicinity of the mouth of the Great Fraser River, though actually not in the valley of that stream. More fortunate than Portland, Vancouver has been able to flank a troublesome river with its floods and shoals while still taking advantage of its valley on its rail route through the mountains. The port has been built in a land-locked bay called Burrard Inlet, surrounded on nearly all sides by towering hills which give the location a most beautiful setting. The area of the entire inlet inside the entrance is 23.6 miles, with a shore line of upward of 50 miles; but the port proper, as at present developed, utilizes only a small fraction of this. The shores are mainly of rock formation; the tidal range is 11 ft. mean and 16.4 ft. extreme. There is no ice and the harbor is perfectly sheltered and has good anchorage.

The port facilities, as developed so far, are mainly on the south side of the east 5.5 miles of the Inlet. The portion of the Inlet comprising the harbor is about 1⅓ miles in width, connecting with the Gulf of Georgia on the west and the remainder of the Inlet on the east by two narrow channels designated First and Second Narrows, respectively. These Narrows were formed by the deposit of gravel, sand, and small boulders brought down by mountain streams on the north side of the Inlet and deposited in the shape of extensive bars. The narrows are deep, but only about 500 ft. in width. Navigation through them is seriously handicapped by strong tidal currents, which, at the First Narrows, reach as high as 8 knots per hour at spring tide, and are such a menace to navigation that the Dominion Government has undertaken to widen the entrance by dredging to 1,200 ft. The improvement will not affect the current perceptibly, but will give more leeway for the navigation of ships. In most portions of the harbor the tidal currents interfere seriously with the berthing of ships.

New Westminster.—Ten miles south of Vancouver on the Fraser River, and 16 miles above its mouth, is the town of New Westminster, which is taking active steps to develop port facilities for deep-sea shipping. The Fraser is a large river, not unlike the Columbia, but with a channel less difficult to improve and maintain. The ordinary tidal range at the port is only 5 ft., but the range between high and low water in the river is 14 ft. Reference will be made in another place to the steps being taken to develop this port.

Victoria.—This has been an important port in the past, and is so still, though its commercial business is not large. It is the chief port of Vancouver Island and on it is located the capital of British Columbia. The commercial port is on a small land-locked inlet with bald rocky shores. A few miles to the west is the celebrated Esquimault, an excellent port, strongly defended, and, prior to 1905, the headquarters of the British North Pacific Naval Squadron.

Prince Rupert.—This harbor is on an island within a well-sheltered inlet on the "inside passage" to Alaska, a little north of the mouth of Skeena River, the valley of which stream is the route of the western division of the railroad. The area of the entire inlet in front of and back of the island is about 27 sq. miles, and that of the shore line is about 80 miles. The tidal range is large, the maximum being 27 ft. and the mean about 14. The harbor is perfectly sheltered and is free from ice.

The port is very new, and its development has only begun. It now has about 2,700 ft. of berthing space, of which 600 ft. belongs to the Provincial Government and the rest to the Grand Trunk Pacific. It has a sectional dry dock 600 ft. long. The newness of the port and the fact that rail connection east is not yet opened, give little as yet for comparison with other ports. Its record lies all in the future.

The promoters of this important terminal enterprise adopted the almost unique course in civic growth of laying out their city before its occupancy by settlers began. It has been scientifically planned by artists of national reputation, and, if the plans are followed, it will be spared the disfiguration characteristic of most American cities.

The development of the ports of the Pacific has evolved a great range of engineering problems, some of which are of unusual magnitude, difficulty, and cost.

The subaqueous basaltic rock excavation at the eastern end of Victoria Harbor was performed by the drilling method. The single drill was mounted on a platform float that could be raised clear of high tide by steam power spuds. Steam was furnished from boilers on a barge. Thirty-two holes were drilled at one setting of the raised platform. The holes were 2.5 in. in diameter, drilled to a depth of 2.5 ft. below grade (20 ft. at low water), and spaced 3 by 3 ft. The actual cost for drilling and blasting only was $6.17 per cu. yd., without interest, depreciation, or plant renewal.

The blasting in Vancouver Harbor will be a more delicate operation, as it will be carried on in close proximity to constructed piers. Holes 3 in. in diameter, spaced 5 by 5½ ft. centres, will be drilled to a depth of 3 ft. below the required grade line (36 ft. at low tide), and shot off in series. It is expected that 1½ lb. of dynamite per foot or more will be used. The estimated cost for drilling and blasting is $5.60 per cu. yd. Dredging of the broken rock will approximate an additional $1 per cu. yd. The Vancouver rock is a sloping sandstone ledge overlaid with from 3 to 7 ft. of gravel, hardpan, and disintegrated sand rock.

Probably the most effective dredging plant for all purposes on the Pacific Coast is the Frühling, built in Germany in 1906 at a cost of $275,000 exclusive of duty and cost of steaming to British Columbia. It is the property of the Department of Public Works of Canada, and operates on the Fraser River. It is of the "Frühling" scraper suction type, elevating material by a pair of 16-in. centrifugal pumps through pipes and delivering to hoppers inside the hull. It is a sea-going dredge, of steel construction throughout, and is self-propelled by twin screws. Its length between perpendiculars is 187 ft.; the extreme beam is 34.5 ft., the draft, loaded, about 14 ft., and the hopper capacity at this draft

800 cu. yd. Its performance from April 1st, 1910, to March 31st, 1911, was as follows:

Hours worked	862.5
Cubic yards excavated	924,800
Average cubic yards per hour	1,072
Average cubic yards per day of 9 hours, including all delays	3,000
Maintenance cost	$37,948.10
Repairs cost	8,835.58
Total cost	46,783.68
Cost per cubic yard	$0.0505

The Grand Trunk Pacific dock at the foot of Madison Street, Seattle, is a recent structure. It is 625 ft. long, 128 ft. wide, and is supported entirely on creosoted piles, the length of the bearing piles varying from 55 to 90 ft., with bracing piles as long as 110 ft. The bents are 10 ft. apart, and the piles in the bents are spaced from 6 ft. centres at the inner end to 3 ft. at the centre. The capping and floor systems are of very thorough construction, and the dock appears to have thorough stability, notwithstanding the great depth of water in which it stands.

The main shed is 90 ft. wide, with a platform 8 ft. wide on the south side and 16 ft. on the north, the latter carrying a railroad track. There are five adjustable slips on each side and one at the outer end worked by worm gear. The fender piles are of tight-bark fir and are driven two at every bent and fastened to 12 by 12-in. stringers with ¾-in. straps. At the outer end they are spaced 3 ft. apart, and clusters of seven piles are driven at the outer corners. The timber used in construction was 241,775 lin. ft. of creosoted piling, 71,000 ft. B.M. of creosoted bracing, and 1,113,000 ft. B.M. of other lumber. In its finish, offices, equipment, and general lay-out, it is the best example of dock construction on Puget Sound.

The second of the docks selected for a brief description here is the Great Northern dock at Vancouver, B.C. It was designed by A. W. Münster, M. Am. Soc. C.E. The pier is 450 ft. long by 293 ft. wide, with a berthing space of 30-ft. depth at low water on each side, and with two sheds, 403 by 102 ft. Between the buildings is a space 41 ft. wide. The distinctive feature of the structure is a cantilever platform supported on cylindrical concrete piers, which themselves rest on a sandstone ledge. These piers are 4.5 ft. in diameter, with a base enlarged to 10 ft. The foundation is carried down into the hardpan or sandstone ledge to a minimum depth of 3 ft. below the bottom of the slip. The piers will have an average height of 52 ft. On top of them will be placed a longitudinal concrete girder, 3 ft. wide and about 7 ft. in depth, which will carry the transverse girders forming the immediate support of the floor slab, which are placed 12.5 ft. centre to centre. The transverse girders are from 2 to 3 ft. wide, 6 ft. deep, and 51 ft. long. They will project 16.5 ft. beyond the line of the piers and, acting as a cantilever, will carry corresponding parts of the front platform. The inner end of these girders will rest on a line of 16-in. concrete piles driven to refusal and stayed in position before the rock embankment is placed. The floor slab is to be 7 in. thick. The concrete platform and beams have been designed for a distributed load of 500 lb. per sq. ft. The railroad track running the length of the platform is placed centrally over the longitudinal girders. The reinforced concrete construction supporting the track is proportioned to carry a 100-ton switch engine. Tie-rods encased in concrete will anchor the concrete platform firmly to the embankment.

The warehouse buildings are of wooden construction covered with galvanized iron. The roof is to be carried on

[illegible] a comparative study of the rates in the different ports with a view of determining the relative tax on commerce in each. In order [illegible] of terminal charges and a comparison of the principal Pacific Coast ports a purely hypothetic case has been [illegible] draft, discharging and loading cargoes of 12 000 tons of miscellaneous freight, the ship remaining in port 12 [illegible] but it is apparent that, because of the complex and diversified tariffs, as well as [illegible] averages except through an assumption that is somewhat strained. The cost of [illegible] 40 cents per short ton at all the ports. This is not strictly true, but the labor unions may be relied on to [illegible] the length of a day's work. Small miscellaneous items like water, etc., are insignificant, and have been [illegible] a variable sum. The attempt has been made to arrive at an equitable average for each port [illegible] 15 cents per month per lineal foot of dock rental. A 500 ft. space will amount to $225 [illegible] make the rental $225 per voyage.

trusses spanning the whole width of the building, leaving an unobstructed floor space. The floor inside of the building will be paved with creosoted blocks on a concrete base. The concrete slabs on the outside platform are to be covered with an asphalt wearing surface. The cost of the completed dock and buildings will be approximately $1.50 per sq. ft.

British Columbian Ports.—The British Columbian ports, particularly Vancouver, are wholly private-ownership ports, and the water-front development is almost exclusively in the hands of the railroads. It is a striking contrast to the great Canadian port of Montreal, which is one of the most progressive public-ownership ports in the world. Vancouver is passing through the boom experience of most new localities in the West, and is willing to make almost any concession to private interests for what promises most for the immediate present. Not until after the present period of expansion has passed, and public thought, now absorbed in speculation activities, has time to take stock of the situation, is it likely that the problems of port control will be given very serious consideration.

The British Columbian ports being still almost exclusively under railroad control and ownership, as far as port facilities are concerned, the rates are privately controlled, and the charges are absorbed largely by the railroads.

Vancouver, B.C.—As already stated, no comprehensive scheme of development of this port has been adopted. Special studies have been and are being made of different parts of the harbor, and there are rumors of gigantic development plans by private interests. The Great Northern Railway has a fine new pier under construction and other private improvements are in progress; but there is as yet no general plan, no distinctive scheme of port administration, and no provision of public funds.

The conformation of the harbor and the handicap of tidal fluctuation and currents have suggested an improvement which, though costly, would seem to possess great merit. That is to place a lock and dam across the throat of the harbor at the second Narrows, thus holding the upper part of the Inlet at high tide and making it a fixed-level fresh-water harbor. This would restrict the tidal area to one-third its present extent and would reduce tidal currents in the lower harbor so much as greatly to improve conditions there. It would seem on the face of it that this would be an improvement of great importance to the future of the port.

New Westminster.—The fresh-water port of New Westminster is taking active steps in harbor development. It has recently expended $15,000 on the study of a plan and its presentation and is about to put into effect the one prepared for it by A. O. Powell, M. Am. Soc. C.E. It comprises wide, marginal streets, routes for railways, the extension of the city quay, and a long waterway in a slough parallel to the river, from which the river is to be excluded at the upper end. A succession of parallel slips, oblique to the axis of the waterway, will develop a berthing space of 7½ miles.

Victoria.—Even that sometime staid and delightful provincial town of Victoria, more distinctly British than any other port of the Pacific, has become infected with the Panama bacillus and is cogitating what it may do to be prepared for the changes which it has been told are about to ensue. No definite plans have as yet been evolved, but among the tentative suggestions are an outer harbor to be protected by a breakwater in front of the present entrance to the inner harbor; and also a development in Oak Bay on the opposite side of town fronting to the eastward

Prince Rupert.—Studies for the port of Prince Rupert are now in progress under the direction of Mr. Bogue, but are not yet far enough along for incorporation in this paper. A suggestion that has been made of possible future development in this port, however, may be properly mentioned

Prince Rupert City is on an elliptically shaped island about 6 miles long north to south by 4 miles east and west. The "lakes" which separate the island from the mainland in the rear have an area north of the railroad crossing of about 40 sq. miles. It is not unlikely that the north and south passages will be dammed off and provided with locks, thus converting the lakes into a tideless, fresh-water harbor just at the level of high-tide. While this development is still some distance off, it has such great advantages, in view of the extreme tidal fluctuation in Prince Rupert harbor, that it will probably be realized eventually.

BRIQUETTING BITUMINOUS COAL

In the modern methods of mining bituminous coal large quantities of slack are produced; and while in some sections of the country there is a market for the slack, for use in industrial plants provided with mechanical stokers, in other sections there is little or no market for it, states "Conservation." For this reason a number of the operators in Nova Scotia are considering the installation of briquetting plants for the purpose of converting this slack into a higher grade and more suitable fuel.

On account of the friable nature of the coal mined at the MacKay Mine much slack is made during mining operations. As there is little or no market for this slack coal the management installed a briquetting plant with a capacity of 10 tons of briquettes per hour.

This is the first plant to be installed in Canada for the purpose of briquetting bituminous coal. Unfortunately, it was damaged by fire during the month of July.

The same company are also installing two similar units at the Colonial Mine, which are expected to be in operation this year.

The briquetting plants are of Belgian manufacture and are of the roll press type.

The following is a short description of the MacKay briquetting plant:

The coal from the mine is screened over a ¾ inch screen; the lump coal (over ¾ inches) is sent to the market, and the fine coal is carried by a disc elevator to a 75 ton bin. The coal is discharged from the bin by chute into a 10 ton concrete pocket situated at the briquetting plant. The coal is then elevated by a bucket elevator to a 3 ton cone hopper. The coal is fed from the hopper to the disintegrator at any desired rate of speed by means of a revolving table and plough-shaped cutter situated at the bottom of the hopper.

The pitch after being crushed is fed into the disintegrator by means of a similar adjustable feed. From the disintegrator the coal and pitch is elevated to the mixer where superheated steam is added. The heated coal is then conveyed to the roll press by means of a spiral conveyer. The briquettes are usually soft as they come from the rolls but upon becoming slightly cool they become hard and withstand handling very well.

The pitch used as a binder for the briquettes varies from 6 to 8 per cent. of the weight of the coal. This pitch is one of the by-products obtained from the tar recovered at the Dominion Iron and Steel Company's oven plants.

The briquettes are ovoid in shape and have been used with considerable success upon the Intercolonial Railway and for domestic purposes.

The Inverness Railway and Coal Company are also installing a briquetting plant at Inverness, C.B., for the purpose of briquetting the slack made during mining operations.

Briquettes when properly made with a suitable binder possess the several advantages over raw fuel.

RAILROAD EARNINGS.

The following are the railroad earnings for the week ended September 14th:—

	1911.	1912.	Increase or decrease.
C.P.R.	$2,325,000	$2,667,000	+ $342,000
G.T.R.	1,026,449	1,110,000	+ 84,065
C.N.R.	378,300	[illegible]	− 18,000
T. & N.O.R.	39,366	28,573	− 10,793

New records in both gross and net earnings are shown in the C.P.R. statement for the month of August, issued on Saturday. Gross exceeded by about $200,000 the gross in July, when earnings for the first time passed the $12,000,000-mark. Net profits were $36,800 ahead of net in October of last year, the previous record month for the company in this respect. The gain in net in August as compared with the same month last year was $642,354, or nearly 16 per cent. The statement for the month follows:—

	August, 1912.	July 1 to August 31, 1912.
Gross earnings	$12,251,715.87	$24,304,114.45
Working expenses	7,553,790.21	15,138,011.89
Net profits	$4,717,925.66	$9,166,102.56

In August, 1911, the net profits were $4,075,571.01, and from July 1st to August 31st, 1911, there was a net profit of $7,773,599.34. The gain in net profits for the same period last year is, therefore, for August, $642,354.65; and from July 1st to August 31st, $1,387,503.22.

A cable to The Montreal Star says:—"The Grand Trunk August statement shows that the net profits for the Grand Trunk increased £35,200 sterling. Canada Atlantic showed a net decrease of £2,550. Grand Trunk Western, net increase of £6,850. Grand Haven, net decrease of £1,950.

The total profit for the whole system increased £37,550, which is regarded by the market as a fine showing.

◆

PANAMA CONSTRUCTION ESTIMATES

In thirteen months a vessel will go from the Atlantic to the Pacific Ocean through the Panama Canal, according to [illegible] Canal Commission. October 15th, 1913, is the tentative date set for the passage of the first boat through the canal. The "christening" will be done by a naval vessel. President Taft [illegible] in charge of canal construction work. The President's approval of the new canal opening programme is awaited. [illegible]

[illegible]

[illegible]

The big dam, locks and spillways projects show stages [illegible] that the Gatun locks will require about 2,000,000 cubic yards of concrete work. To September 15th well over 19,000,000 cubic yards has been put into place. The concrete work of the Pedro Miguel locks is nearly 95 per cent. completed, and that of the Miraflores locks over 92 per cent. The Gatun spillway will probably be completed within another month. Other engineering features show an equally advanced stage toward completion.

The canal will have a summit elevation of 85 feet above sea level, to be reached by a flight of three locks located at Gatun, on the Atlantic side, and one lock at Pedro Miguel and a flight of two at Mira Flores, on the Pacific side. Each lock will have a usable length of 1,000 feet, and a width of 110 feet, which will be the minimum width of the canal.

The canal is to be about 50 miles long from deep water in the Caribbean Sea to deep water in the Pacific Ocean. The channel will vary in width from 1,000 at a point just south of the Gatun locks, to 30 feet at a point near the Pedro Miguel lock. There will be a number of places where several boats can pass abreast of each other and the minimum depth will be 41 feet.

LARGE TURBINES FOR RIO DE JANEIRO.

After having supplied, in 1908 and 1909, six units, each of 9,000 horsepower, for the Rio de Janeiro Tramway, Light and Power Company and their power station at Pirahy, Messrs. Escher Wyss and Co., of Zürich, are installing two more turbines, each of 20,000 horsepower, so that the works will altogether have available nearly 100,000 horsepower. The firm has supplied the turbines (Pelton wheels) as well as the pipe system. The turbines are provided with vertical shafts, which are suspended, the wheels being at the lower ends. The nozzles, of which there are four to each wheel, are controlled quite independently of one another by levers from a servo-motor. Two discharge-ports are provided in the wheel-casings in case of accident. A sluice-valve is also arranged on the supply main; this valve and the outlets are operated by the pressure regulator. These measures are very necessary, since the turbines work under a head of 286 m. (940 ft. nearly), and, running at 300 revolutions per minute, consume about 6.2 cu. m. (219 cu. ft.) of water per second. Each turbine is combined with a set of two three-cylinder high-pressure pumps for the oil feed, which supply 360 litres (80 gallons) of oil per minute. These are also constructed by Messrs. Escher Wyss and Co., and are driven by small Pelton wheels. There is a pressure-bearing between the turbine and generator, in addition to the foot-step, which has to support a load of 76 tons—the weight of the revolving parts. The new hydraulic mains leading to the power station have a length of 700 m. (0.44 mile), and a diameter of 1,300 mm. or 1,400 mm. (51 in. or 55 in.), like the old mains, but they are secured by stand-pipes, 150 metres in length. The mains alone weigh 5,000 tons.

◆

The government has let the contract for the last section of the Hudson Bay Railway which it is hoped to complete by [illegible]. The last section extending from Split Lake to the bay, [illegible] to Port Nelson and [illegible] miles long to Fort Churchill. This last link is to be built by Mr. J. D. [illegible]. It is said to be the intention of the Hon. Frank [illegible], as the result of his visit to Hudson's Bay, to run a railroad to the bay by electricity. A plant may be built at [illegible] on the Nelson River. The Nelson River, he reports, has wonderful power possibilities, and could supply [illegible] of the West. The total available power is estimated at [illegible] horsepower.

A NEW TYPE OF SEWER PIPE.

Until the present time engineers in England and the United States have recognized the fact that some form of vitrified clay segment blocks for large sewers would be a most desirable material with which to construct large sewers and as a result of this fact many styles of segment sewer blocks have been invented. None have been successful for the reason that those which could be made economically of clay did not have any provision for end joints.

Those inventions which did provide for satisfactory form of end joints were of such a shape that they could not be made economically of clay. Therefore with the solution of the only objection that has arisen by providing a ship-lap joint for the ends of the blocks, which will hold a sufficient quantity of mortar so that a tight joint can be made and retained, the American Sewer Pipe Company of Akron, Ohio, have solved the problem and are presenting a successful vitrified salt glazed segment sewer block.

These blocks are made in one and two foot lengths, also in three different types, for construction of sewers ranging from 30 inches to 108 inches in diameter; detailed description of each being shown in the enclosed table.

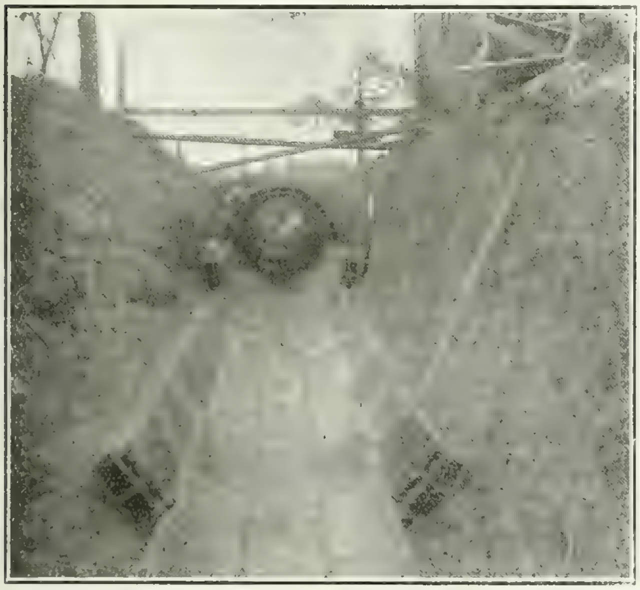

Fig. 1.

The material from which these blocks are manufactured are the celebrated Akron shale and Ohio River clays, which are acknowledged to be among the best adapted to the requirements of sewer construction, and when made in relatively thin sections, attain a perfect vitrification. In these blocks all the walls are of a thickness to which these clays best lend themselves for a perfect vitrification.

The outside surface of the blocks, being the part with which the sewage comes in contact, is the part requiring the highest glaze and it is possible to secure almost absolutely perfect glaze.

A test of Type A Block showed a crushing strength of 3,040 pounds per square inch, pressure being applied at weakest point, viz., between webs.

The end joint is made in the style of the ship-lap joint and is made possible by a web or system of webs, which provides backing for the mortar and an annular space is secured which, when filled with mortar, produces a tight sanitary joint.

The mortar joints on the dove-tailed sides are scratched to assist in retaining the mortar. The blocks are made as large as can be conveniently handled and have an inside area of approximately 270 square inches each, thus eliminating, in a large measure, the objectionable feature of numerous joints.

The outer openings in the hollow block system of sewer construction are well adapted to carrying surface water and are also of special value to the contractor, when constructing a sewer in a wet trench, as, after the invert is laid a drain is effected which carries a large amount of water and leaves a perfectly dry sewer for construction of the arch. This obviates the necessity of laying under drains.

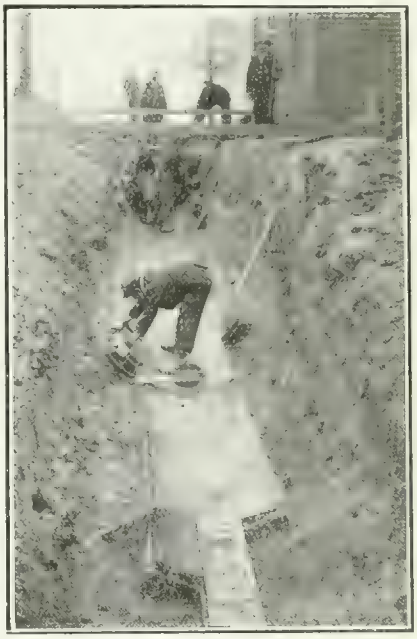

Fig. 2.

In soil where it is possible the trench is excavated as near the shape of the outer shell of sewer as possible, and the bottom of invert block laid ahead for drainage purposes and to proper line of grade. The successive tiers are thoroughly tamped at the back. A template is used as high as the spring line, after which a form for the arch is required and for which a collapsible form has been designed which greatly facilitates the work. The male and female dove-tailed joints are so constructed that only the key block requires slipping in endwise. All other blocks drop into place on the side. After forms have

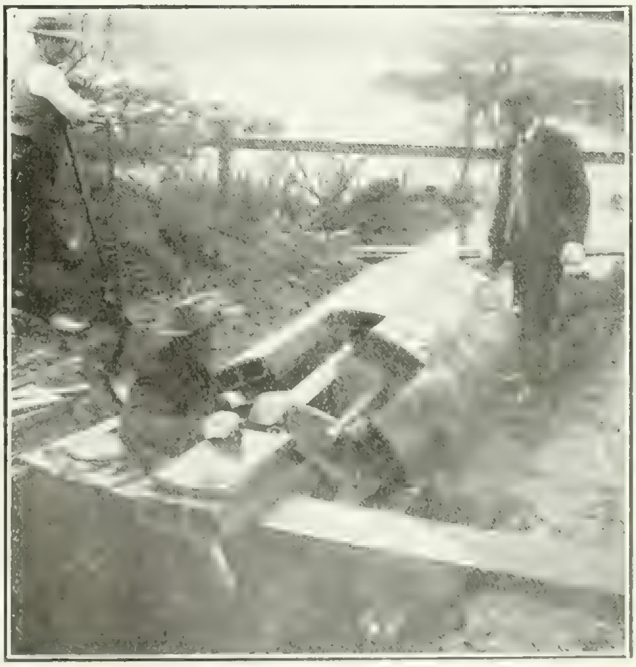

Fig. 3.

been removed all joints are pointed and all spilled mortar removed from the inner surface of the sewer. The backfilling commences immediately upon collapse of form or as soon after as feasible. The earth is thoroughly tamped to fill voids from pulling sheeting.

At the discharge or spill end of sewer a concrete apron is usually installed to insure against washing away of tamping or foundation.

The city of Flint, Mich., recently completed a 42 and 48-in. outfall sewer built of salt glazed vitrified clay segment blocks. A construction view of this sewer is shown in Fig. 1.

Sewers built of these blocks in the manner described are said to be watertight. They also are as durable and impervious as vitrified pipe. The frictional resistance to the flow of water in these sectional block sewers is claimed to be considerably less than any other type of construction adapted to the same class of work. At the same time tests have shown that the load carrying capacity is large. The type of block construction here described is manufactured by the American Sewer Pipe Co., of Akron, Ohio.

◆

KEEPING RECORDS OF MUNICIPAL IMPROVEMENTS AT FARGO, N.D.*

The city engineer's department has felt the need of complete and accurate maps of the city for all purposes, and I believe, and in some instances know, that serious errors have been made by relying on maps that were unreliable.

Two sizes of maps have been adopted for our use. A large map on a scale of 200 ft. to the inch shows all sections, quarter-sections, additions, streets, avenues, alleys, and blocks and lots. On these maps will be plotted all municipal improvements, such as sewers, water mains, sidewalks, paving, and such general information as can be of use. This size is for wall purposes.

A second size is made up on a scale of 100 ft. to the inch and each sheet contains one quarter-section, making the size of the sheet 26 x 26 in. On this map, in addition to data on the larger maps, are sewer wyes, sewer connections, water-main connections, valves, shut-off boxes, hydrants, paving, openings in paving and date made, cost of special improvements against each lot, sidewalks, new buildings, the lighting system and a great deal of minor data connected with the above. At present none of these data is collected in a compact form that can be used to any advantage and [illegible] the needs of the city. In no other way can such information be kept available for instant use than by progress maps. This work has taken a great deal of labor and painstaking [illegible]

There are no more valuable records in any engineer's office than progress records and maps, and this applies with [illegible]

[illegible]

for information, that we should be able to give and that it is the function of the city to provide to its citizens, that cannot be given because of lack of records. It is the aim to eliminate this state of affairs as rapidly as is possible. The data must be picked up in all manners of ways and time is the greatest factor in its completion.

The lack of records in the office is an unfortunate condition that has hampered our work greatly during the past two years. Efforts to remedy this defect have in some cases proved effectual, but in other cases there is no remedy whatever. As such may be mentioned lack of actual cost of contract work, time when certain contracts were begun, progress of same and time of completion; surveys made, results and conclusions; location of monuments, opening in streets, street lines, grades for sidewalks and streets and data upon which made; data upon which sewer and water mains have been designed, and cost of office work.

A complete office system has been started in order to eliminate these defects in the records. The loose-leaf system is used throughout. The lack of notes on surveys, time the men were employed on any piece of work and sidewalk records, was most noticeable and this has been remedied. The loose-leaf system of field notes was adopted, and a filing system is used which I have every reason to believe is original. The field-note sheets are 4¾ x 7¼ in. These sheets are pasted on 5 x 8-in. division index cards which have the usual 5-cut tab. On this tab the character of the work is printed and the indexing completed. The time of men employed and any class of work is kept in a similar manner.

For the purposes of engineering the records of costs have been divided into heads as follows: Board of Health; Bridges; Dam; Maps; Monument Lines; Office Supplies; Park Commission; Paving; Pay Roll; Requisitions; Sewers; Street Grades; Street Lines; Waterworks; Water Mains and Sidewalks. Each of these is subdivided into two heads: (1) Construction, and (2) Maintenance. Each of these subheads is subdivided again into Labor, Material; Engineering and Estimates.

◆

TRANSPORTATION QUESTION IN CALGARY.

The proposed piping of natural gas to Winnipeg from the Bow Valley by Calgary capitalists, with four or five pumping stations, commencing somewhere about Swift Current, which would force the gas to Winnipeg, is meeting with various objections. Mayor Spencer, of Medicine Hat, objects to a charter being granted the new company, and the Calgary Herald demands either Provincial or Dominion prohibitive legislation.

The Interurban Railway Company is acquiring 13 acres of the industrial tracts owned by the city, for use as the site of a repair shop.

A mile of street railway track is to be built by the South East Calgary Corporation, from Ogden station to the city limits. This will be handed over to the city of Calgary in return for a service operated by the municipal system over the tracks of the South East Corporation.

Plans of the Western Dominion Railway Company, considered by the board of trade this week, have the name of J. E. Askwith as president. This did not, however, convey enough information to the committee, and they decided to recommend approval of the map filed provided the promoters could assure them of immediate construction. The line is variously ascribed to the Canadian Pacific Railway, Canadian Northern Railway and Great Northern interests. It will [illegible] between the international boundary and the Peace district (passing through Calgary), which contains a vast [illegible] of clays, shales, coal, natural gas, tar, sands, and possibly oil.

A NEW SYSTEM OF ILLUMINATION TO AVOID GLARE BY DIFFUSION.*

By Hans K. Ritter, E.E., Assoc. Mem. A.I.E.E.

There are three distinct devices which are utilized to make up a modern illuminant: First, the source of light or lamp; second, the reflector or redistributor of light; third, the diffuser or softener of light.

It is the combination of these three devices into an efficient unit, its framing into a supporting structure or fixture, and the final application to our many varied needs, that are the problems of the illuminating engineer of the present day.

The tungsten lamp, mercury arc, etc., have all distinct distribution characteristics of light flux emitted by them, inherent to them; that is, they are dependent on the mechanical arrangement of the light-emitting surfaces. These characteristics cannot in general be adjusted so that a fully satisfactory light-distribution for all the necessary applications of the lights is found. To accomplish the latter, the first accessory mentioned, the reflector, is now universally used.

Most modern illuminants have such a high intrinsic brilliancy that a correction is necessary to make them agreeable to our eyesight. To accomplish this, diffusing envelopes, such as globes, spheres, etc., are widely used.

At the present time, it is common practice to combine lamp and reflector, or lamp and diffusing globe. To combine lamp, reflector, and diffuser efficiently, many difficulties arise, as all know who have seriously attempted to make this combination. The failure to create such a unit accounts for the deficiency of many lighting installations.

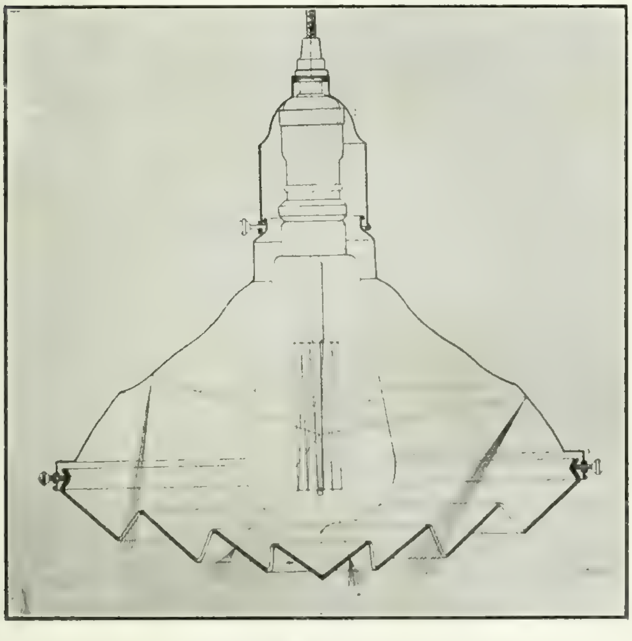

Fig. 1.

My experience shows me that it is a comparatively easy matter to make a reflector for a certain redistribution of light, but a much harder task is set if the reflector is to act as diffuser and efficiently shield the glaring source of light.

Most of the diffusing globes diffuse the light, but have no action in redistributing it efficiently.

However, to make certain a fully satisfactory arrangement, we are bound to combine lamp, reflector, and diffuser into one unit, and only so are able to produce an illuminant which is hygienic and fully satisfies our demands for ease and comfort.

Many attempts have already been made to successfully solve this problem. The most common of them is the frosting of the electric lamp bulbs; but this remedy cannot be said to fully cover this problem, as the frosting leaves the reflector surface unscreened within the field of vision, and even then the lamp's intrinsic brilliancy is high. Incidentally, sand blasting the bulb tends to diminish the effective life of the lamp, reducing it to some degree and, according to several authorities, to a large extent. It is therefore better to use clear glass bulbs, screened by a diffusing envelope large enough to keep the intrinsic brilliancy down. Another method employed to screen the source of light is by means of indirect illumination. An investigation of this method shows that it cannot be generally adopted, as its applicability and efficiency, in most cases, are dependent on the preparation of ceilings and walls.

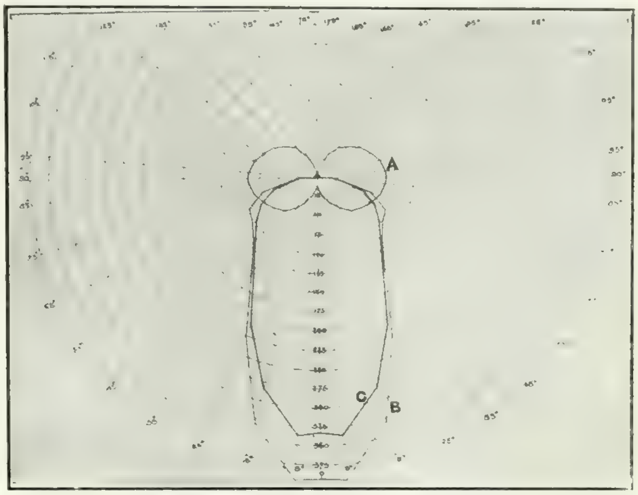

Fig. 2.

It was about the time when the Nernst lamp was at its height, and especially used for better lighting, that in the firm of Messrs. Ritter and Uhlmann, in Basel, fixture manufacturers of note in Switzerland, research tests were conducted under the direction of Mr. J. J. Ritter to find an arrangement which would embody in an efficient and proper manner the three fundamental components, namely, lamp, reflector, and diffuser in one unit, combined.

Especially the relation of many problems which arose in the practical and artistic application of fixtures to illumination and which had to be solved, was responsible for the creation of many new shades and types, and our efforts resulted finally in the invention of the combination that I am describing, patented in this country as well as abroad.

In principle, this combination comprises an upper reflector and a lower glass distributor or diffusing envelope. These totally enclose the light source in such a manner that no direct rays from the filament leave the fixture without coming from one or the other of the supplementary diffusing surfaces, the attached translucent glass, or the matt reflector within.

The lower disc, as you will see in the cut, Fig. 1, is made up of concentric, truncated cone surfaces, alternately erect and inverted. This embodies the fundamental principle of this invention. The inwardly sloping surfaces of the inverted cones are matted. The outwardly sloping surfaces of the erect cones are of clear glass.

---

*Paper read at the Annual Convention of the Illuminating Engineering Society, Niagara Falls, Ontario.

Direct rays of the filament pass through the inwardly sloping cone surfaces of the diffuser, which are matted so as to completely hide the source of light. While this translucent surface hides the image of the filament, it is not dense enough to affect the efficiency greatly.

Rays which do not go directly from the filament to the diffuser, strike the reflector surface. From this they are reflected back downward and pass out through the outwardly sloping cone surfaces of the glass, which are clear. Again, those rays which are reflected from the matted surface of the diffuser, strike the reflector, and from there pass out through the clear glass of the diffuser. I am inclined to think that this class of rays deserves more attention than is usually given to it, and that it adds materially to the efficiency of the combination. A maximum outlet for the whole spherical flux is thus provided through the lower surface, most of the light undergoing only a single diffusion. This, in addition to the correct matting of the translucent surfaces, contributes to the unusual high efficiency of this combination.

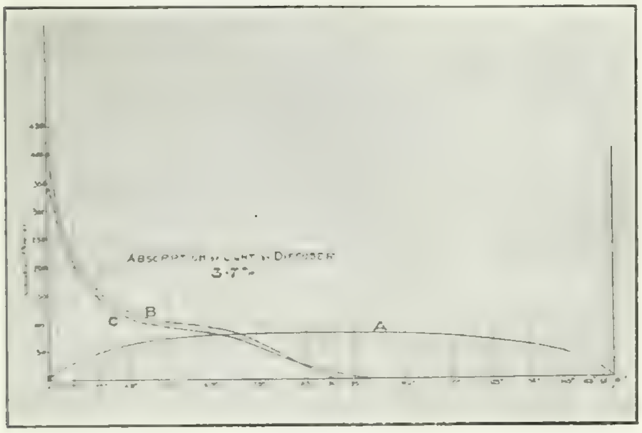

Fig. 3.

In Fig. 2, the polar diagram, curve A, shows the shape of the distribution curve for a 100-watt lamp without accessories; curve B, when a matted aluminum reflector is employed, and curve C shows the effect of the diffuser added.

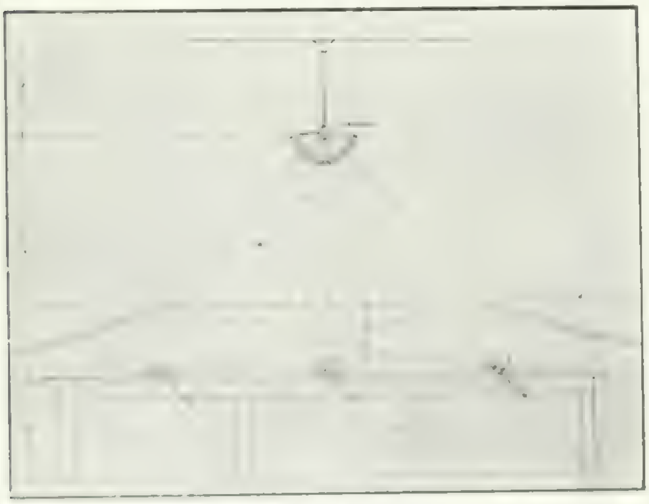

Fig. 4.

[illegible]

From the Reousseau curve (Fig. 3), you may note that the absorption of the diffuser amounts (curve C) to 3.7% of the total light flux (curve A).

But the efficiency is supplemented by other favorable points in this combination. The unit is practically dustproof. No dirt can hang on to the inner diffusing or reflecting surfaces, so the maintenance cost is low.

The size of the diffusing envelope depends upon the size of the lamps used, so that for a small lamp small units are fabricated and for large lamps, large ones.

Before I go over to the practical application of this unit as an efficient illuminant for the lighting of working planes, I wish to emphasize that from no point beneath the fixture can the filament itself been seen through the clear glass surfaces. Eye protection is therefore afforded to the fullest extent.

Innumerable applications can be made of this unit when suspended vertically; but with the advent of the wire-type tungsten lamp no necessity exists to use these lamps only in a vertical or upright position. By means of the patented diffuser described, we can with equal efficiency employ the lamp at any desired position.

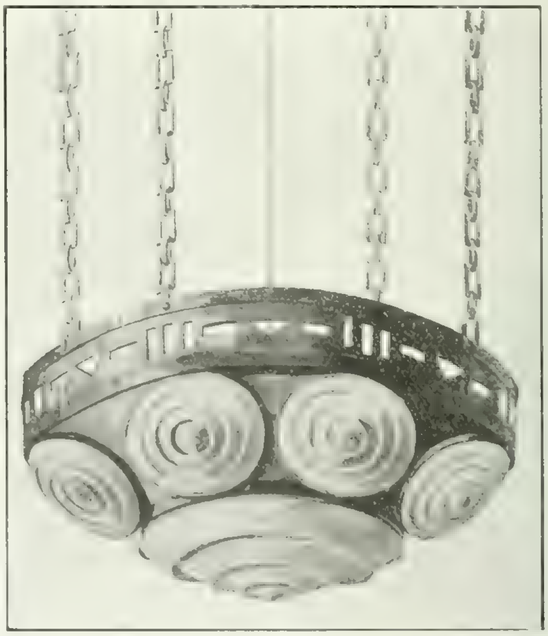

Fig. 5.

It is widely known that a series of sources of light, distributed in a given space and employing one type of reflector hanging vertically, give an even light distribution only when given a certain spacing distance and placed above a certain height.

For a light source in a reflector placed on an angle, the light distribution being of the focusing type, it is different. It is only necessary to find the angle which would correspond to an even illumination of a zone on the working plane, and any lowering or raising of the fixture does not affect the even distribution of light in one zone on the working surface. In Fig. 4 such a condition is shown. By the point-by-point method the illuminating values are projected on the working plane and the resulting illumination values computed.

A material saving of light is thereby effected, as the highest intensity is actually brought in the working zone. Further, by using a cluster, a saving of outlets required, results.

For instance, in the conditions considered, two 60-watt lamps, each placed in a unit as described and standing at

45° against the vertical, thus being grouped as a cluster, the spacing distance would be about 15 ft., with a vertical hanging distance of 6 ft. 6 in. from the working plane.

In Fig. 5 a fixture is shown built up of the above units, which is designed for use as a church fixture. This fixture is built up of the following: First, a group of six diffusers placed at 45° to the vertical, each 12 in. in diameter, and enclosing one 100-watt tungsten lamp; second, one diffuser placed vertically 16 in. in diameter and holding three 100-watt tungsten lamps; third, three reflectors each holding one 60-watt tungsten lamp, these being used for ceiling illumination.

From the picture it can be noted that the framework of the fixture is such that the reflectors are hidden from view. The bulb, also, of the electric lamp, which as I found really never adapted itself to be brought into an artistic shape, is covered up and a compact and efficient arrangement is found in which all parts serve a useful purpose, readily adaptable to decoration.

Many styles of fixtures can be created, almost all of which appear artistic and attractive in form.

The principle laid down through the combination of lamp, reflector and an efficient diffusing envelope is not exhausted. The field for application is a very large one to employ these means to eliminate glare. The combinations and applications of these units are so numerous that it is almost in order to call it a new system of illumination created through the employment of a diffusing envelope having a very high efficiency in connection with reflector into one unit.

To recapitulate, we have in this system:

(1) Means provided to reduce the intrinsic brilliancy of a source of light to any desired extent.

(2) The disc, being of flat shape, adapts itself admirably for building fixtures to give any desired lighting or artistic effects.

(3) The reflector unit, being totally enclosed, makes it practically dustproof, which means minimum attention after installation.

(4) On account of its independence upon actual surroundings it has a very large field for application.

(5) Our experience in Europe shows that the high commercial efficiency, together with the small attention required after installation and the low cost of installation, more than offsets the slightly higher factory cost.

AMERICAN ROAD CONGRESS.[*]

By E. A. James.[†]

The American Road Congress, a conference composed of road users, road builders and road machinery men, held at Atlantic City, October 1st to 5th, was successful beyond expectation. Although held at the very busiest season of the year, yet the attendance was large, the exhibits varied and extensive and the papers and addresses of a high order.

In the exhibition hall the exhibitors of the United States Road Department and of the various state departments clearly demonstrated the progress being made in highway construction, both in theory and practice, while the displays by the manufacturers show clearly that they appreciate the large field opening in road work on this continent.

The delegates were welcomed by Woodrow Wilson, Governor of New Jersey, and in view of his place in the public mind at the present some of his remarks are of unusual interest. Governor Wilson said in part:

"The question of highways is a question which has interested by thought, particularly in recent years, because it is one of the few great instrumentalities of our public life and of our communial life with which the government is of necessity connected. The government is not, in the United States, expected to build railroads. The government is not as yet expected to own railroads. Railroads differ from other highways, though we often speak of them as the highways of our commerce, in this important particular, that only those who own them can use them in the matter of putting vehicles upon them—that a particular set of individuals by reason of their control of the road, have the exclusive right-of-way over it.

"We must more and more engage the government in providing the general facilities of the common life. There is no breach in that of any of our older understandings of the function of government. We have never doubted that the government had the right to supply these facilities which private endeavor has never been expected to supply. Therefore, we are not upon a new ground of theory; we are merely upon a new ground of tactics, and when I think of what the highways mean, I seem to be thinking of the whole history of the human race. Whenever I used to read stories I remember my imagination was most fascinated when the characters went on a journey and met the rest of the world.

"On the old highway, particularly the old English highways, you met everybody from the King to the beggar, from the King to the highwayman. You were there in a way to have the adventure, the whole experience and adventure of English life, because it was there that English life interlaced and crossed and was fluid, flowing from one region to another, and by the same token it was upon the highways that men got the contacts which result in the building up of public opinion.

"I was trying to illustrate the fact one day that in some of our great cities there is no public opinion, in a way which led me into trouble. I said, that what generally happened to a man in a city was that when he got in a public vehicle or on a highway, he doesn't talk to anybody, but if he can hold himself steady enough, that wherever he happend to be he plunges his head into the morning newspaper and experiences a reaction which he calls his opinion, but it is not an opinion at all, it is simply the impression that a piece of news or an editorial has made upon him and he cannot be said to be participating in public opinion or in opinion at all until he has laid his mind alongside the minds of his neighbors and discussed with them the incidents of the day and the tendencies of the time.

"Where I got into trouble was, that I ventured to use this illustration. I said that public opinion was not typified on the streets of a busy city, but was typified around the stove in a country store where men sat and probably chewed tobacco and spat in a sawdust box and made up, before they got through, what was the neighborhood opinion both about persons and events; and then, inadvertantly, I added this philosophical reflection, that whatever might be said against the chewing of tobacco this at least could be said for it: that it gave a man time to think between sentences. And ever since then I have been represented, particularly in the advertisements of tobacco firms, as in favor of the use of chewing tobacco.

As a means of reflection, I dare say that it is wholesome; otherwise I will not declare my opinion about it at all.

"But the illustration, nevertheless, was an illustration of what I think is pertinent to us, or rather pertinent to my thought in connection with what you are doing. You know how the Roman empire used to throw its great highways out from Rome until they touched the limits of the empire—until they threaded even the distant island of Britain; and it was like throwing thongs out to bind all the empire together. Now, the initial purpose of those highways was to afford an open road for the armies of Rome so that she could throw her power rapidly in any direction; but Rome also, in my imagination at any rate, prepared her destruction by those highways because she could not open them to her own armies without opening them also to the people that lived upon their edges, and they could not touch one another without forming an opinion about the Roman power, without intermingling the influences of different nations, for these roads did not stop at national confines, and the Roman roads threaded the opinion of the world together into an axus and pattern, and I tell you very frankly that my interest in good roads is not merely an interest in the pleasure of riding in automobiles, it is not merely an interest in the very much more important matter of affording the farmers of this country and the residents in villages the means of ready access to such neighboring markets as they need for their economic benefit, but it is also the interest in weaving as complicated and elaborate a net of neighborhood and state and national opinion together as it is possible to weave.

---

[*] *The Canadian Engineer* will publish from week to week verbatim reports of the more interesting addresses.

[†] Engineer for the York Highway Commission.

"It is of the most fundamental importance that the United States should think in big pieces, should think together, should think ultimately as a whole, and I felt, in my enthusiasm for good roads something of the old opposition that there always has been in me to any kind of sectional feelings, to any kind of class feeling.

"The reason that city men are not more catholic in their ideas is that they do not share the opinions of the country, and the reason that some countrymen are rustic is that they do not know the opinion of the city and they are both hampered by their limitations. I heard of a lady the other day who had lived all her life in the city and in a hotel. She made a first visit to the country and spent a week in a farmhouse. She was asked afterwards what interested her most about her experience and she said that it was hearing the farmer page his cows.

"A very urban point of view with regard to a common rustic occurrence, and yet that language showed the sharp, the inelastic limits of her thought. She thought much more narrowly than in the terms of a city. She thought in the terms of a hotel, and in proportion as we are confined within the walls of one hostelry or city, or one state, we are provincial, and national thought cannot successfully build itself upon those foundations in a way that will be permanent; so that I believe that the development of great systems of road[illegible] speaking, as well as physically speaking, a task in statesmanship.

"I believe that it is the primary study of the statesman to bind communities together and open their intercourse so that it will flow with absolute freedom and facility. No one argument ought to be omitted; every class has its argument for good roads, and putting them all together they form an irresistable mass of arguments, but the result of [illegible] the United [illegible] the energies of the [illegible]

[illegible]

to lend the aid of the government to the actual task of development.'

"That has been the general attitude of our government up to this time. It cannot be that attitude any longer. There are things of this sort for example, you take not merely the matter of good roads and the carrying of goods to market, but of what goods there are to be carried to market, the production, the agricultural production per acre in the United States does not favorably compare with the production per acre in the older countries of the world and the margins are approaching one another.

"We used to lead the world and our grain exports were our chief exports, but the exports of grain are going down and down because the other margin is coming up, the margin of domestic demand and the population is increasing faster than the product so that a great deal of our commercial history is about to be altered by the circumstances of agricultural production, and I believe that it is the proper function of the government to see to it that by the extension of all the varied modern knowledge about agricultural process and about the characteristics of different soils ought to be so extended, so carried everywhere to the farmer as to build up by the aid of the government this thing that feeds us and ought to continue to feed the world; and whenever you speak of that, whenever you increase what the United States is doing, you must immediately increase the facilities of the United States for handling what it has made after it has made it. You cannot rationally increase the prosperity of this country without increasing the road facilities of this country."

"I remember having a very interesting and, for me, enlightening conversation with a mountaineer once in the North Carolina mountains. He was very hot against the excise taxes which made it practically impossible for him, without becoming a criminal, to make whiskey out of his corn, and I discussed it somewhat minutely with him in order to get his point of view. His point of view was simply this; he had a little farm that was a fertile pocket in a remote part of the mountain. It didn't pay him to take his corn to the market as corn, because by the time he got to the market, the very horses that were hauling it would have eaten it up, but he could profitably get it to the market as whiskey.

"His point was simply this, that it was unreasonable for the government to forbid his getting a market for his corn in the only way in which it was possible for him to get a market. Now, while we might say that it was not desirable that there should be any market at all for the product that he wished to sell, nevertheless, the illustration will point my moral, namely, that it is not worth while producing until you can release what you produce and that the only way of releasing it is by the most facile methods of inter-communication and transportation.

"We are merely threading the energies of a nation together, linking them in a single pattern, or rather, we are merely setting them free when we facilitate and promote the interests of a congress like this. I need not tell you, therefore, that I am in deep sympathy with the purposes of this congress, because in my judgment that would simply be like claiming that I was a rational being and I hope that does not require argument.

"I would rather admit it than try to prove it, and if you will allow me to admit I am a rational being, you will allow me to say that as a matter of course, I am profoundly interested in the purposes of this Congress, and I consider it an honor that the State of New Jersey should have the pleasure of harboring you for a little while and entertaining you for a little while in consultation about what is, at bottom, a great national interest."

Good Roads an Economic Necessity.

Dell M. Potter, Arizona and California:

"I do not own an automobile," said Mr. Potter, "nor do I own stock in any automobile corporation, but I know that the men who have money own automobiles, and if you want to get them into your States and have them learn the climate and soil conditions, together with their other attractions, you must furnish good roads upon which they may travel in comfort. The prosperity of the country depends upon the automobile, and the sooner we come to a realization of this fact the better it will be for us. Governor Wilson rightly said in his speech of yesterday that there is a limit upon farm products in this country because of poor roads. The roads of our country are in worse condition than those of any nation of the world. The policy of this United States Government as it affects the prosperity of the country is a thing wonderful to behold.

"Within the past year we have driven out of the great Northwest from 25,000 to 40,000 of our best citizens because they were not able to make a living on their farms, and all that prevented them was the vile condition of our roads. Nine-tenths of the money appropriated by Congress for public improvements goes into our rivers and harbors and but a small fraction into good roads. I have no fault to find with the practise of appropriating money for the rivers and harbors, even though it does benefit only the great corporations, but I contend that it is time the niggardly policy maintained towards our highway system was abandoned.

"There are 850,000,000 acres of farm land in this country and less than half of it is under cultivation, because of the inability of those who would work the land to get their produce to a market. Upon the products of these farms depends the prosperity of the country, and good roads are vitally essential to such production."

Marking Highways.

As a preface to his address on the establishment of a National Department of Highways, Frank D. Lyon told of the plan adopted in New York of designating various routes through the State by colors, and of the use to which telegraph and telephone poles were put in this connection. By this system, he said, it was possible for tourists to make their way from one point to another throughout the State without the aid of books or maps. Then, launching into his scheme for the establishment of the Federal Department for the supervision and construction of roads, he elaborated upon the plan and explained many of the details as they had been worked out by him. With the establishment of such a department, he said, its head could go from State to State, urging the establishment of similar departments and guaranteeing Federal aid in the construction of whatever roads were considered necessary. Whatever highways in the various States were designated as national highways would be maintained by the State and Federal Government sharing equally in the expense. The plan so appealed to the delegates in attendance that it was freely predicted some definite scheme towards its adoption would be worked out before the congress came to a close.

Maintenance of Roads.

It was admitted by all that American road systems were failing because of poor maintenance.

Logan Walter Page, president of the congress, was enthusiastic in reference to work accomplished. He said in part:

"Never before have there met in this country so many people or so many interests having for their object the betterment of the public roads. When we consider the great activities manifested during the last few years for the promotion of this most necessary work, it is astounding that so much has been accomplished in so short a time. As a matter of fact, more has been done in the last two decades than in the previous two thousand years. It engenders something more than the methods of construction and maintenance. Back of these problems are intricate questions of finance, which are involved in the issuance of bonds, the levying and apportionment of taxes, the accounting and safeguarding of road funds. Co-ordinate with the question of finance we may place those of promotion, legislation, organization, administration, construction and maintenance. Probably few other questions have been productive of so much legislation as that of roads. It is absolutely essential to sound progress in the road movement in this country that our highway be simplified and perfected.

"It is not admitted that the policy of placing convicts at work in the construction of roads or the preparation of road materials is wise in all cases.

"Although it is generally conceded that the most serious defect in our road system in this country is lack of maintenance, we have been making progress at a very slow rate to remedy this defect. It is high time that action is taken leading to a strong, concentrated and intelligent campaign in every State, not only in the maintenance of our roads in the highest state of efficiency, by the enactment of legislation that will provide definite annual appropriations and continuous and skilled attention, but the administrative phase of the question as well."

The speaker declared that the road situation, as it is to-day is that "we have two million and a quarter miles of public roads, eight per cent. of which have undergone some measure of improvement or have had something done to them; of this eight per cent. of so-called improved roads, probably not more than a half of four per cent. of the total, really deserve to be classed as improved roads. If we accept the general assertion that twenty per cent. of the roads carry ninety per cent. of the traffic, it follows that we have before us for improvement sixteen per cent. of the total mileage of the country, or 360,000 miles."

He asserted that the annual expenditures for this work in the United States was but half that spent by the United Kingdom on its 150,000 miles of roads; allowing but $417 per mile, or hardly enough for maintenance alone. "When we consider that a very large percentage of the $150,000,000 appropriated for this purpose is wasted, not so much through dishonesty as through ignorance and defective administration, it is apparent that the actual amount expended usefully on the roads is far less than the figures show. I believe that proper administration would save the country annually $40,000,000 of this amount and do the same work that is now being accomplished."

One of the most interesting resolutions proposed was the following:

"Resolved, that the president of this American Road Congress appoint a committee of five to formulate and suggest to several highway associations of the country, a proposed form of legislation to regulate and control the use of the public roads and highways by the automobile truck and other self-propelled trucks and traction engines; to the end that the good roads of the country may be protected from the present destructive tendency of their use by excessively large and heavily loaded vehicles of the class herein described, and for the further purpose of obtaining a general expression of opinion on this subject which may result in uniform legislation throughout the several States to regulate the same."

It is fortunate that action is being promptly taken in connection with this important feature of highways before the vested interest becomes too large.

Mr. W. A. McLean, provincial highway engineer for Ontario, gave a very interesting address on "Road Improvement in Canada." *The Canadian Engineer* expects later to publish this address in full.

◆

COAST TO COAST.

Porcupine, Ont.—The gold shipped from this centre in September will aggregate $500,000.00.

Toronto, Ont.—Fifteen young men of the forestry class, University of Toronto, have left for the study of practical forestry on the shores of Lake Nipegon.

British Columbia.—In order that the $2,000,000 bridge to be erected by the Canadian Pacific Railway across the Pitt River may be started, a large bridge now in use will have to be removed.

Ottawa, Ont.—The management of the Ottawa Light, Heat and Power Company will apply at the next session of the legislature for power to increase their capital from $2,000,000 to $5,000,000.

Guelph, Ont.—The past year has been an excellent one in building circles, as may be readily seen in the report of the city engineer's department. Over one hundred houses, with a value of $294,961.00 have been erected. The total building permits are over $500,000.00.

Montreal, Que.—The harbor commissioners' new grain elevator, officially opened by Hon. J. D. Hazen, October 2nd last, has a length of 456 feet, a width of 100 feet, and a storage capacity of 2,620,000 bushels. It is the largest concrete grain elevator in the world. A complete description of the elevator appears in *The Canadian Engineer* of October 3rd.

St. John, N.B.—New rates for electrical power in this municipality have been published as follows: On installation of 25 h.p. with a base rate of ten cents per kilowatt monthly consumption of not less than $70, 33 per cent. discount; $84, 36 per cent. discount; $100, 39 per cent. discount; $125, 42 per cent. discount; $140, 45 per cent. discount. Additional discount of ten per cent. from the net amount (for cash) if paid within ten days of presentation of bill, is authorized.

Vancouver, B.C.—The survey is completed for the double tracking of the C.P.R. between Calgary and the coast, and work will be commenced at twelve points on the route within six months. The construction will be rushed as swiftly as possible and there is a prospect that the line will be completed almost as soon as the Panama Canal is open for traffic. The second line will be approximately parallel to the present main line of the C.P.R., but the grade through the Rockies will be materially reduced. The cost of the undertaking is estimated at about $[illegible], the expenditure in some districts exceeding $100,000 per mile.

Toronto, Ont.—As a number of parties have requested that the time be extended for the return of the comments respecting the proposed rules and regulations for public utilities, the Hydro-Electric Power Commission of Ontario have consented to the extension of the time for the return of these comments to the [illegible] of December next, 1912. Comments should be forwarded to Mr. W. W. Pope, secretary, Continental Life Building, Toronto.

Toronto, Ont.—Professor L. B. Stewart, of the University of Toronto, who has spent the last four months in the new part of Ontario, the Keewatin area on Hudson Bay recently added to the Province of Ontario, has returned to Toronto. During the summer he had been engaged in surveying and laying out a portion of the new district. While the land within fifty or sixty miles of the Bay is mostly marsh and muskeg, the swamp is not of any great depth, and Professor Stewart is of the opinion that it could easily be drained and would offer no serious obstacles to railroad construction. Engineers of the Hudson Bay Railway are in the field locating a line, and contractors are at work grading from Pas Mission northward for several hundred miles.

Fredericton, N.B.—It is reported that the Grand Falls Company, Limited, the new company headed by Sir William VanHorne, which is to spend upwards of $8,000,000 in the development of the water power at Grand Falls and the erection of vast pulp and paper mills, is making the first move towards commencing with its undertaking. At the present meeting of government an order-in-council is being passed empowering Hon. J. K. Flemming, as surveyor-general, to convey by deed to the company the water power and five acres of land along the banks of the river upon payment of the sum of $60,000. Below the falls only one-half the river can be conveyed to the company, the other half being held by the Crown for ordinance purposes. Recently the government was notified that the Grand Falls Company, Limited, was prepared to pay over the $60,000 and take a deed of the property and rights and the deed has been prepared by Attorney-General Grimmer and will probably soon be executed.

Grand Trunk Pacific.—Rapid progress is being made with the construction of stations along the main and branch lines of the Grand Trunk Pacific Railway, and an effort is to be put forth that will result in a station being erected at every stopping place from coast to coast with the completion of the line. Out of a total of 237 stations, 79 have been completed, 58 are in various stages of construction, while 100 remain to be erected. The work on the construction of the G.T.P. stations is as follows: Main line, Winnipeg to Fitzhugh, 159 stations, 69 completed, 44 under construction, and 46 not started. Yorkton branch, 10 stations, 2 completed, 5 under construction, and 3 not started. Regina branch, 17 stations, 4 completed, 3 under construction, and 10 not started. Calgary branch, 32 stations, 4 completed, 3 under construction, and 25 not started. Prince Albert branch, 19 stations, 3 under construction, and 16 not started.

Montreal, Que.—The gates of one chamber of the St. Gabriel lock in the Lachine Canal at Montreal were wrecked September 24 by a boat collision that resulted in draining the adjacent upper level of the canal and caused a total interruption of navigation. The two chambers of the lock are side by side just below the Rue des Seigneurs swing bridge. Below them the basin is crossed by the Wellington Street swing bridge. The steamer "Glenmount" had just passed through the lock and the upper swing bridge, leaving the upper gates still open, when the steamer "Nevada," also up-bound, ran into the lower gates and tore them from their hinges, allowing the water from the upper level to escape in a wave [illegible] ft. high into the lower level. The flood tore one of the upper lock gates from its hinges and carried it, together with the two lower gates, into the lower level of the canal. Although her engines were in operation the "Nevada" was unmanageable and was turned completely around and carried up against the bank at the lower end of the basin, while the "Glenmount," also under steam, was swept down through the lock into the basin. A barge heavily loaded with sand [illegible] from its anchorage above the upper bridge and swept through the lock and basin to the lower swing bridge, where it brought up against the fender and bridge girders, doing some damage. A diver and derrick boat have been put at work in the basin to attempt to raise the gates and [illegible] them. A portion of the gate gear that were torn from their frames have been found uninjured and it is hoped that the gates will be found serviceable.

Toronto, Ont.—The long-pending arrangements for the construction of a union station at Toronto, Ont., seem destined to further delay. Following a conference last week the Railway Commission has called on the Grand Trunk and the Canadian Pacific to present within three weeks a joint statement showing the exact status of the negotiations between the two companies regarding the project. In the meantime the railways announce that they will have entered an appeal to the Governor-General in Council against the viaduct order, thereby re-opening the whole viaduct and union station issue. The Canadian Pacific declares that it is not party to any order respecting the union station yet made by the Commission and therefore is not subject to the present order. The road's counsel declared that the determination of the plans for the union station depended entirely on whether or not the viaduct scheme was to be carried out, and reiterated the unalterable opposition of his company to that scheme. The plans could not be decided until the track level was fixed. It is expected that the railways will ask for the appointment of a board of three independent engineers of acknowledged eminence to prepare a joint recommendation. Such a board could report in time for work to be begun in the spring.

◆

ROYAL ARCHITECTURAL INSTITUTE.

The Royal Architectural Institute of Canada opened its seventh annual meeting in Ottawa on October 7th, addresses of welcome being extended by Mayor Hopewell and C. P. Meredith, president of the Local Chapter of the Ontario Association of Architects.

The Institute will meet next year in the city of Calgary. A resolution was passed by the Institute reorganizing it as the representative body of the Federated Provincial Associations. The Royal Architectural Institute of Canada has a membership of 550 in all parts of Canada.

F. S. Baker, president of the Institute, retired, and the following officers were elected: President, H. C. Russell, of Winnipeg; vice-presidents, Messrs. George Long, of Calgary; A. F. Wickson, of Toronto, and G. A. Monette, of Montreal; honorary secretary, Alcide Chausse, Montreal; honorary treasurer, J. W. H. Watts, Ottawa.

* * * *

MANITOBA ASSOCIATION OF ARCHITECTS.

The annual meeting of the above was held in Brandon, Man., on Saturday, September 28th last. The following were elected officers for the coming season: President, W. Fingland; vice-presidents, W. A. Elliott and J. Prender West; secretary, R. G. Hanford; treasurer, W. F. Nichols. Several important questions were dealt with, including the new Winnipeg building by-laws, the Selkirk memorial competition and the annual meeting of the Royal Architectural Institute of Canada, to be held in Ottawa in the near future.

* * * *

ONTARIO SOCIETY OF ARCHITECTS.

At a meeting of the Ontario Society of Architects the following were elected officers for the coming season. The annual convention of this body will meet in the city of Ottawa during the middle of October. President, C. P. Meredith, Ottawa; first vice-president, Jules F. Wegeman, Toronto; second vice-president, A. C. Bond, Toronto; treasurer, J. P. Hynes, Toronto; registrar, H. E. Moore, Toronto. The other members of the council are: Professor Wright, Toronto, and Fennings Taylor, Ottawa.

CANADIAN STREET RAILWAY ASSOCIATION.

The Canadian Street Railway Association met last week in London. A number of papers were read by members of the association, and officers were elected for the year as follows: President, Mr. Patrick Dubee, Montreal; vice-president, Mr. C. B. King, manager of the London street railway; secretary-treasurer, Mr. Acton Burrows, Toronto; executive committee, the officers and Messrs. R. Hooper, St. Johns, N.B.; J. E. Hutchinson, Montreal; J. D. Fraser, Ottawa; W. Phillips, Winnipeg, and J. E. Coleman, Hamilton.

* * * *

REGINA ENGINEERING SOCIETY.

The Annual Meeting of the Regina Engineering Society was held last week and the following officers were elected. No new nominations were offered and the men who have served during the past five months of the society's existence were unanimously re-elected. They are as follows: Hon. president, J. G. Sullivan; president, A. J. McPherson; first vice-president, H. S. Carpenter; second vice-president, L. A. Thornton; secretary, J. A. Gibson; treasurer, E. I. Wenger; corresponding secretary, R. O. Wynn-Roberts.

The address of the evening was a paper on "Good Roads," read by A. J. McPherson.

Mr. McPherson reviewed the history of road making in Saskatchewan, but dealt chiefly with the progress which had been made since 1906 and the methods adopted. His paper dealt with the whole question from the standpoint of the government, and showed what progress had been made since the adoption of the first policy of having the money provided for this purpose expended under local supervision, which resulted in its being done only when no other work could be undertaken, through successive steps up to the present system under which the supervision of the making of main roads is entirely under the supervision of the commission. He showed how the steps which had been taken had resulted in having a large body of men scattered over the province, all of whom were intelligent road builders.

The work of construction, when of any extent, such as construction of roads through sloughs, through rough country and the building of bridges over twenty feet span, is done by the government while the maintenance of roads built with government assistance and the upkeep of the ordinary roads is left to the municipalities.

In the discussion which followed the paper Mr. Carpenter drew the attention of the engineers to the fact that there was a dearth of road engineers throughout the country and that many municipalities were refraining from entering upon extended plans of road building because they could not get men competent to direct the work.

◆

PERSONAL.

MR. LOUIS B. STEWART, Professor of Surveying of the University of Toronto, who has been north for the Dominion Government, settling the boundary between Manitoba and Ontario, is back in Toronto.

MR. WILLIAM KENNEDY, JR., of Montreal, will in all probability be retained by the fire, water and light committee of Winnipeg as consulting hydraulic engineer in connection with the Point du Bois power plant.

MR. G. C. BATEMAN, B.Sc., late of the staff of the Dome Mines, in Porcupine, has been appointed to succeed Mr. A. D. Miles as Canadian representative of the Canadian Mining and Exploration Company. Mr. Bateman is a gradu-

[illegible] of Queen's University, and is an experienced mining man.

MR. PATRICK WELCH, of the firm of Foley, Welch and Stewart, has resigned from the vice-presidency of the Pacific and Great Eastern Railway Co., and has secured the contract to build this line throughout its length from North Vancouver, B.C., to the Grand Trunk Pacific main line. Mr. Welch has established headquarters at Lillooet and will begin operations immediately.

MR. LOUIS B. STEWART, Professor of Surveying of the Canadian Society of Civil Engineers, has been appointed by the Government to investigate work done in the construction of the National Transcontinental Railway under the old commission. An investigation has been in progress for some months by George Lynch Staunton, K.C., of Hamilton, and F. P. Gutelius, formerly with the C.P.R.

◆

COMING MEETINGS.

THE CANADIAN HIGHWAY ASSOCIATION.—Meeting will be held in Winnipeg, Man., October 9th to 12th. Secretary, P. W. Luce, Room 4, Cunningham Block, New Westminster, B.C.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.—Annual Convention will be held at Baltimore, Md., October 15th to 17th, 1912. Secretary, C. A. Lichty, 226 Jackson Blvd., Chicago, Ill.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Annual Convention to be held at Dallas, Texas, November 12th to 15th, 1912. Secretary, A. P. Folwell, 50 Union Square, New York.

AMERICAN RAILWAY ASSOCIATION.—Nov. 20th. Annual Meeting at Chicago, Ill. Secretary, W. F. Allen, 75 Church St., New York.

THE INTERNATIONAL ROADS CONGRESS.—The Third International Roads Congress will be held in London, England, in June, 1913. Secretary, W. Rees Jeffreys, Queen Anne's Chambers, Broadway, Westminster, London, S.W.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Ninth Annual Convention will be held in Cincinnati, December 3, 4, 5 and 6, 1912. Secretary, E. L. Powers, 150 Nassau St., New York.

THE INTERNATIONAL GEOLOGICAL CONGRESS.—Twelfth Annual Meeting to be held in Canada during the summer of 1913. Secretary, W. S. Lecky, Victoria Memoriam Museum, Ottawa.

◆

ENGINEERING SOCIETIES.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—413 Dorchester Street West, Montreal. President, W. F. TYE; Secretary, Professor C. H. McLeod.

KINGSTON BRANCH—Chairman, A. K. Kirkpatrick; Secretary, L. W. Gill; Headquarters: School of Mines, Kingston.

OTTAWA BRANCH—
177 Sparks St. Ottawa. Chairman, S. J. Chapleau, Ottawa; Secretary, H. Victor Brayley, N.T. Ry., Cory Bldg. Meetings at which papers are read, 1st and 3rd Wednesdays of fall and winter months; on other Wednesday nights in month there are informal or business meetings.

QUEBEC BRANCH—Chairman, W. D. Baillairge; Secretary, A. Amos; meetings held twice a month at room 40, City Hall.

TORONTO BRANCH—96 King Street West, Toronto. Chairman, T. C. Irving; Secretary, T. R. Loudon, University of Toronto. Meets last Thursday of the month at Engineers' Club.

VANCOUVER BRANCH—Chairman, C. E. Cartwright; Secretary, Mr. Hugh B. Fergusson, [illegible] Carter Cotton Bldg., Vancouver, B.C. Headquarters: McGill University College, Vancouver.

VICTORIA BRANCH—Chairman, F. C. Gamble; Secretary, R. W. MacIntyre; Address P. O. Box 1290.

WINNIPEG BRANCH—Chairman, J. A. Hesketh; Secretary, E. E. Brydone-jack; Meets every first and third Friday of each month, October to April, in University of Manitoba, Winnipeg.

MUNICIPAL ASSOCIATIONS

ONTARIO MUNICIPAL ASSOCIATION.—President, Mayor Lees, Ham.; Secretary-Treasurer, Mr. K. W. McKay, County Clerk, St. Thomas, Ontario.

SASKATCHEWAN ASSOCIATION OF RURAL MUNICIPALITIES.—President, George Thompson, Indian Head, Sask.; Secy.-Treasurer, E. Hingley, Radisson, Sask.

THE ALBERTA L. I. D. ASSOCIATION.—President, Wm. Mason, Bon Accord, Alta.; Secy.-Treasurer, James McNicol, Blackfalds, Alta.

THE UNION OF CANADIAN MUNICIPALITIES.—President, Chas. Hopewell, Mayor of Ottawa; Hon. Secretary-Treasurer, W. D. Lighthall, K.C., Ex-Mayor of Westmount.

THE UNION OF NEW BRUNSWICK MUNICIPALITIES.—President, Councillor Siddall, Port Elgin; Hon. Secretary-Treasurer, J. W. McCready, City Clerk, Fredericton.

UNION OF NOVA SCOTIA MUNICIPALITIES.—President, Mr. A. S. MacMillan, Warden, Antigonish, N.S.; Secretary, A. Roberts, Bridgewater, N.S.

UNION OF SASKATCHEWAN MUNICIPALITIES.—President, Mayor Bee, Lemberg; Secy.-Treasurer, W. F. Heal, Moose Jaw.

UNION OF BRITISH COLUMBIA MUNICIPALITIES.—President, Mayor Planta, Nanaimo, B.C.; Hon. Secretary-Treasurer, Mr. H. Bose, Surrey Centre, B.C.

UNION OF ALBERTA MUNICIPALITIES.—President, Mayor Mitchell, Calgary; Secretary-Treasurer, G. J. Kinnaird, Edmonton, Alta.

UNION OF MANITOBA MUNICIPALITIES.—President, Reeve Forke, Pipestone, Man.; Secy.-Treasurer, Reeve Cardale, Oak River, Man.

CANADIAN TECHNICAL SOCIETIES

ALBERTA ASSOCIATION OF ARCHITECTS.—President, G. M. Lang; Secretary, L. M. Gotch, Calgary, Alta.

ASSOCIATION OF SASKATCHEWAN LAND SURVEYORS.—President, J. L. R. Parsons, Regina; Secretary-Treasurer, M. B. Weeks, Regina.

ASTRONOMICAL SOCIETY OF SASKATCHEWAN.—President, N. McMurchy; Secretary, Mr. McClung, Regina.

BRITISH COLUMBIA LAND SURVEYORS' ASSOCIATION.—President, W. S. Drewry, Nelson, B.C.; Secretary-Treasurer, S. A. Roberts, Victoria, B.C.

BRITISH COLUMBIA SOCIETY OF ARCHITECTS.—President, Hoult Horton; Secretary, John Wilson, Victoria, B.C.

BUILDERS' CANADIAN NATIONAL ASSOCIATION.—President, E. T. Nesbitt; Secretary-Treasurer, J. H. Lauer, Montreal, Que.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.—President, Wm. Norris, Chatham, Ont.; Secretary, W. A. Crockett, Mount Hamilton, Ont.

CANADIAN CEMENT AND CONCRETE ASSOCIATION.—President, Peter Gillespie, Toronto, Ont.; Secretary-Treasurer, Wm. Snaith, 57 Adelaide Street, Toronto, Ont.

CANADIAN CLAY PRODUCTS' MANUFACTURERS' ASSOCIATION.—President, W. McCredie; Secretary-Treasurer, D. O. McKinnon, Toronto.

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa; Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler, Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto. President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa; Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp; Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, Ottawa; Secretary, H. E. Moore, 195 Bloor St. E., Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, Major. T. L. Kennedy; Hon. Secretary-Treasurer, J. E. Farewell, Whitby; Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, J. E. Ganier, No. 5, Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. Gibson, 2429 Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, F. S. Baker, F.R.I.B.A., Toronto, Ont.; Hon. Secretary, Alcide Chausse, No. 5, Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, J. R. Collins, Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman, Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box 1317, Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. Rosevear, P.O. Box 1707, Winnipeg, Man. Second Monday, except June, July and August at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
10-24	Construction of about 7¾ miles of Combined Sewers, New Westminster, B.C. ....(P. & S.)	10-10
10-24	Supply of 10,400 ft. reinforced concrete pipe, New Westminster, B.C. ....(P. & S.)	10-10
10-24	Supply of 1,660 ft. of 48″ steel pipe, bends and specials, New Westminster, B.C. ...(P. & S.)	10-10

TENDERS.

Calgary, Alta.—Construction of examining warehouse: tenders to be received until October 25, 1912, at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa. Plans, etc., at the office of Mr. H. E. Matthews, superintending architect of the Dominion Public Buildings, in the Province of Manitoba, Winnipeg, Man.; Mr. W. T. Mollard, clerk of works, Regina, Sask.; at the post office, Calgary, Alta., and Department of Public Works, Ottawa.

Dunnville, Ont.—Tenders for 9,640 feet of four and six-inch water mains, together with the necessary valves, hydrants and specials, will be received until October 21st, 1912, at the office of Alan Mair Jackson, superintendent, Board of Waterworks Commissioners. (See advt. elsewhere in Canadian Engineer.)

Father Point, Que.—Tenders for the erection of one wireless telegraph mast will be received until October 10th, 1912, at the office of G. J. Desbarats, Deputy Minister, Department of Naval Service, Ottawa. Plans, specifications, etc., can be seen at the office of the general superintendent of wireless service, Department of the Naval Service, Ottawa, or at the wireless telegraphy station at Father Point, Que., or at the office of the agent of the Marine and Fisheries Department, Quebec, Que.

Grimsby, Ont.—Tenders for the construction of a public building will be received until October 30, 1912, at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa. Plans, specifications and form of contract can be seen and forms of tender obtained at the Independent newspaper office, Grimsby, Ontario, at the postoffice, St. Catharines, Ont., and at this Department.

New Westminster, B.C.—Tenders will be received until October 24th, 1912, for the construction of about 7¾ miles of combined sewers for districts A. B, and "Outfall," in Section No. 2, of Sapperton System. Further particulars may be obtained from J. W. B. Blackman, City Engineer. Plans, etc., at the offices of The Canadian Engineer, and The Contract Record, Toronto. W. A. Duncan, City Clerk. (See advt. in The Canadian Engineer).

New Westminster, B.C.—Tenders for the supply of about 10,400 feet of reinforced concrete pipe of the lock or continuous jointed type, in sizes from 20 to 54 inches, for Districts A, B, and Outfall of Section No. 2, of Sapperton System, will be received until October 24th. Further information may be obtained from J. W. B. Blackman, City Engineer. Plans, etc., at the offices of The Canadian Engineer and The Contract Record, Toronto. W. A. Duncan, City Clerk. (See advt. elsewhere in The Canadian Engineer).

New Westminster, B.C.—Tenders for supply of about 1,660 feet of 48-inch steel pipe, bends and specials, for outfall and syphon of Section No. 2, of Sapperton System, will be received until October 24th, 1912. Further information may be obtained from J. W. B. Blackman, City Engineer. Plans, etc., may be seen at the offices of The Canadian Engineer, and The Contract Record, Toronto. (See advt. elsewhere in advt. in The Canadian Engineer).

Paris, Ont.—Addition and alteration to public building; tenders to be received until October 21, 1912, at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa. Plans, specifications and form of contract can be seen and forms of tender obtained at the office of Mr. Thos. Hastings, clerk of works, Postal Station F, Yonge Street, Toronto, at the post office, Paris, Ont., and at this Department.

Seymour Arm, B.C.—Pile bent wharf: tenders to be received until October 29, 1912, at office of R. C. Desrochers, Department of Public Works, Ottawa. Plans, etc., at this department; at the office of C. C. Worsfold, Esq., district engineer, New Westminster, B.C.; F. W. Aylmer, Esq., district engineer, Chase, B.C., and on application to the postmaster at Seymour Arm, B.C.

Sapperton, B.C.—Tenders for the purchase of the Canadian Government steamer "Georgia" will be received until October 25, 1912, at the office of A. Johnston, Deputy Minister of Marine and Fisheries, Department of Marine and Fisheries, Ottawa. Dimensions of steamer: Length of keel, 60 feet; breadth outside, 11 feet; depth moulded, 6 feet.

Seal Cove, N.B.—Breakwater wharf: tenders to be received until October 30th, 1912, at office of R. C. Desrochers, Secretary, Department of Public Works, Ottawa. Plans, etc., at this department, and at the offices of E. T. P. Shewen, Esq., District Engineer, St. John, N.B.; Geoffrey Stead, Esq., District Engineer, Chatham, N.B.; Postmaster at Seal Cove, Grand Manan, Charlotte County, N.B.

Toronto, Ont.—Tenders for the construction of Section No. 13, of the high level interceptor, will be received until October 22, 1912. Plans, etc., may be obtained at the office of the Commissioner of Works, City Hall, Toronto. G. R. Geary, (Mayor) Chairman, Board of Control. (See advertisement in *The Canadian Engineer*).

Toronto, Ont.—Tenders for the construction of concrete sidewalks on Cedarvale Avenue, and bitulithic pavements on Walmer Road, in the Township of York, will be received up to noon of October 14th, 1912, at the office of Frank Barber, Esq., Township Engineer, 57 Adelaide Street East, Toronto, at whose office plans and specifications may be obtained. (See advt. elsewhere in The Canadian Engineer.

Winnipeg, Man.—Tenders for the supply of labor and materials required in the erection of piers, floor and pavement for the bridge across the Assiniboine River at Arlington Street. Plans, etc., at the office of the city engineer, 223 James Avenue. M. Peterson, secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders addressed to the Chairman, Board of Control, will be received until October 12th, 1912, for the manufacture and delivery of 10,000 drawn wire, Tungsten lamps, and 25,000 carbon filament lamps. Instructions to bidders, etc., may be obtained at the office of the City Light and Power Department, 54 King Street. M. Peterson, Secretary, Board of Control Office, Winnipeg.

Winnipeg, Man.—Tenders for the manufacture and delivery f.o.b., Winnipeg, of D. C. and A. C. Meters, will be received until noon of October 12th, 1912. Specifications, etc., at the office of the City Light and Power Department, 54 King Street. M. Peterson, Secretary, Board of Control Office, Winnipeg.

◆

Welland, Ont.—The municipal council have closed a contract with the Hydro-Electric Commission for a supply of power for this town.

Winnipeg, Man.—The municipal fire, water and light committee considered the matter of enlarging the Point du Bois power plant. According to Power Manager Glassco, this must be done previous to next fall, and he estimates the cost of two additional power units at $[illegible]

◆

GARBAGE, SEWAGE AND WATER.

Stamford Township, Ont. Negotiations have been entered into between the officials of this municipality and the management of the Canadian Niagara Power Company regarding the installation of a waterworks system in the township.

Barrett Specification Roofs

On Four Great Granaries

To cover the four huge granaries illustrated herewith the Canadian Pacific R. R. engineers chose Barrett Specification Roofs for good and sufficient reasons.

These practical men know that these roofs will last *20 years or more.*

They further know that they will need no painting or maintenance expense of any kind and that the net cost per year of service will be infinitely lower than could be shown by any other type of roofing.

It is for these very reasons that Barrett Specification Roofs are used on more first-class buildings in the United States and Canada than any other kind

A big roof generally means a Barrett Specification Roof, for the reason that the cost of big roofs is carefully scrutinized and ultimate economy carefully considered. Small roof areas ought also to have Barrett Specification Roofs, because they are just as economical and satisfactory there.

Copy of The Barrett Specification with tracings ready for incorporation into building plans free on request Address nearest office.

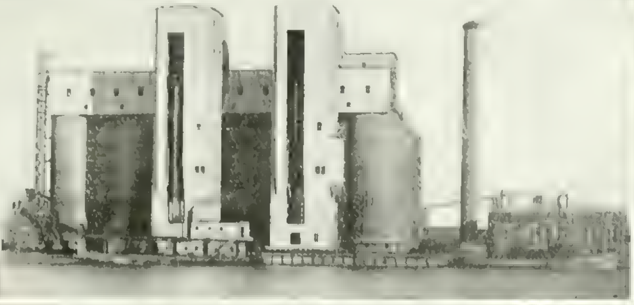
Special Note

We advise incorporating into plans the full wording of The Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired however, the following is suggested:

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15th, 1911, using the materials specified, and subject to the inspection requirements.

THE PATERSON MANUFACTURING CO., Limited
MONTREAL TORONTO WINNIPEG VANCOUVER ST. JOHN, N.B. HALIFAX, N.S.



Sarnia, Ont.—The plans for the new quarter-million-dollar waterworks for supplying pure water from Lake Huron to the citizens of Sarnia and Point Edward have been accepted by the Provisional Board of Health as satisfactory. The by-law will now be prepared and a vote taken by the people.

BUILDINGS AND INDUSTRIAL WORKS.

Brandon, Man.—It is reported that a boot and shoe manufacturing concern are making preliminary arrangements toward locating in this city. Mr. Victor Donaldson is interested in the preliminaries.

Edmonton, Alta.—A. B. Stewart, formerly of Glasgow, Scotland, is opening a factory here for the manufacture of concrete filled steel posts and for making other things of similar construction.

Fort William, Ont.—The plans for the Great West Wire Fence plant to be erected here show a steel and concrete building 125 x 200 feet. The estimated cost is $40,000.

Fort William, Ont.—According to information given by Mr. J. P. Jones, tenders will be called in a few days for the erection of a new financial building to house the Dominion Grain Commission, the Fort William Grain Exchange and the government sample markets.

Fort William, Ont.—A report states that the Grand Trunk Pacific Railway authorities will erect a large freight handling plant in this city.

Fredericton, N.B.—The municipal fire commissioners may erect two new fire stations in this city within the next few months. J. O'Neil, city engineer.

Guelph, Ont.—A number of local men are about to form a brick company and commence manufacturing operations at Monkton. The names of the interested parties so far have not been made public, but Mayor Thorp has expressed his satisfaction of the scheme.

Guelph, Ont.—Plans for the new building for field husbandry in connection with the Ontario Agricultural College have been approved by the Hon. James Duff, Minister of Agriculture. It is to be a two-story brick structure, costing about $40,000 to be taken entirely from the Federal grant.

Islington, Ont.—The management of the Dominion Bridge Company have purchased 10 acres of suitable land at this point and will erect an assembling and storage plant.

Lethbridge, Alta.—The directors of the Lethbridge Brewing and Malting Company are considering a proposition to enlarge their plant at a cost of $[illegible].

Montreal, Que.—Mr. Geo. W. Hill, A.R.C.A., has been commissioned to erect a statue to the memory of the late Sir George Etienne Cartier. This work is to cost $100,000.

Moose Jaw, Sask.—Agreements have been completed whereby the Morley Twine Company, of Sioux City, U.S.A., will establish a plant in this city.

Ottawa, Ont.—The government has purchased from D. D. McGillivray a site for an armory at Port Arthur, the price paid being $[illegible].

Ottawa, Ont.—The addition to the fat stock show building will cost about $19,000.00, according to the lowest tender received, which was from Messrs. Smith Bros. Mr. Burwell is the architect for this work.

St. Felicite, Que.—[illegible]

Todmorden, Ont.—[illegible]

Toronto, Ont.—The management of the T. Eaton Company [illegible]

Vancouver, B.C.—[illegible]

Vancouver, B.C.—[illegible] a new office structure. $125,000.00 is the estimated cost of this work.

Vancouver, B.C.—The members of the congregation of the Kitsilano Methodist Church have planned to erect a new building at a cost of $100,000.00. Rev. Newton Powell is the minister of this church.

Vancouver, B.C.—Twelve houses, to cost between $1,500 and $2,500 each, are to be constructed at Coquitlam, for the Coquitlam Terminal Company by the Coquitlam Construction Company. These houses will be homes for men who are to be employed at the Coquitlam C.P.R. Terminals.

BRIDGES, ROADS AND PAVEMENTS.

Belleville, Ont.—The municipal council have under preparation a by-law calling for a large amount of granolithic pavement. Mr. J. G. Lindsay, city engineer.

CURRENT NEWS.

Middleton, N.B.—Mr. F. W. C. Parsons, chief engineer of the Drummond Iron Mines, states that there is a possibility of an iron and steel works locating a plant near this plant. The plans as proposed at present call for a plant of 250 tons daily capacity with a rolling mill and a bar steel works.

Niagara Falls, Ont.—The municipal council have received the following tenders for the supply and installation of a new centrifugal force pump:

Canadian Foundry Co.	$4,370
Caledonia Iron Works	6,025
Escher-Wyss Co.	4,750
Drummond McCall Co.	6,500
Buffalo Steam Pump Co.	6,244

Ottawa, Ont.—The architects of Canada and the empire are to be invited to submit plans for a new departmental building or group of buildings to be constructed along the bank of the Ottawa River west of the parliament buildings.

Pembroke, Ont.—The management of the Pembroke Shook Mills have been granted a free site and exemption from taxation for 20 years by the ratepayers.

Vancouver, B.C.—According to a report prepared by Consulting Engineer Burwell, the cost of erecting a dam on Seymour Creek will be $632,000. The various items noted in the figures from the engineer were: Construction of concrete dam and intake, $150,000; clearing 400 acres to be flooded by reservoir, $120,000; 48-inch steel main to dam from present intake, 18,600 feet, $186,000; construction of four miles of pipe, line roadway, $20,000; tunnelling, 700 feet, $10,000; cribbing, 600 feet, $3,000; engineering expenses, $27,000; debenture loss and contingencies, $116,000; total, $632,000.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W., during the week ending September 2nd, 1912:

A Scottish firm desire to appoint agents at Calgary, Edmonton, Regina and Medicine Hat, for the sale of their jute cloth, hessians, etc.

A West of England correspondent makes inquiry for the names of Canadian importers of safety pins.

From the branch for City Trade Inquiries, 73 Basinghall Street, E.C.:

A Belgian firm which makes a specialty of importing [illegible] would be glad to hear from Canadian producers seeking export trade.

A London manufacturer of a novelty in gramophone horns desires to communicate with a firm in Canada with a view to arranging exclusive agency for that country.

The London manufacturers of a new portable electric vacuum cleaner are looking for sole agents in Montreal, Winnipeg and Vancouver.

A London firm manufacturing loose leaf account books, and general specialties in stationery and leather goods, wish to arrange for their sale in Canada.

DEPT. OF RAILWAYS AND CANALS, WELLAND

Superintending Engineer's Office,
Messrs. Wettlaufer Bros., St. Catharines, Feb. 7th, 1912.
No. 178 Spadina Ave., Toronto.

Dear Sirs:—Replying to yours of the 6th, I beg to say that the two Mixers received from you last summer proved to be very handy, useful machines. They turned out excellent concrete and we had no trouble with them at all.

Yours truly, J. L. WELLER, Superintending Engineer.

CANADIAN NORTHERN RAILWAY

Belleville, Ont., Feb. 14th, 1912.
Wettlaufer Bros.,
178 Spadina Ave., Toronto, Ont.

Dear Sirs:—I think it is my duty to inform you that I am entirely satisfied with the two Concrete Mixers purchased from you last season. I have tested them in every way possible, and in every case I have found them capable of doing first-class work.

Yours sincerely, J. O. GIROUX.

We have manufactured concrete mixers and concrete machinery of all kinds for many years; also previously had taken contracts for concrete work of all kinds, and have had the actual experience of just what a concrete mixer should do. Wettlaufer Mixers are perfect to-day through the help of the hundreds of contractors who purchased Wettlaufer Mixers in past years. We have gone personally to them and watched these machines working on all classes of work, asked the contractors their opinions, and so have evolved the present perfect mixer.

Compare the thoroughness, simplicity and durability of our mixer with other makes. The Wettlaufer Mixer is of the heart-shaped drum type; this means quick and positive mixing and the saving of power.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

17583—September 23—Authorizing C.N.O.R. to construct across public road between Twps. of Field & Springer, Dist. of Nipissing, Ottawa-Capreol Line.

17584—September 23—Authorizing C.N.O.R. to construct bridge across Ground Hog River, Dist. Algoma, mileage 149.7 from Sudbury Junction.

17585—September 23—Amending Order No. [illegible], by substituting for the plan approved thereunder, the plan filed as plan "A."

17586—September 23—Authorizing C.N.O.R. to construct across C.P.R. at Lansing, Tp. York, Co. York, Ont., mileage [illegible] from Yonge St., Toronto, and rescinding Order No. [illegible], dated March 11th, 1912.

17587—September 23—Authorizing the Town of Point-aux Trembles, Que., to extend, at its own expense, Frontenac St., across tracks of C.N. Terminal Ry. Co., in said town.

17588—September 23—Authorizing the Niagara, St. Catharines & Toronto Ry. to construct spur for the Montrose Paper Company, in Town of Thorold, Ont.

17589—September 24—Directing that the Dominion Express delivery limits in Maple Creek, Sask., shall be those enclosed within Pacific Ave., March St., 4th Ave., and Aspen St.

17590—September 26—Authorizing C.P.R. to construct across highway Station 193.4, between Tps. Blanshard, Co. Perth, and East Missouri, Co. Oxford, Ont.

17591—September 25—Authorizing C.P.R. to reconstruct bridge No. 81.5 on its Woodstock Subdivision.

17592—September 24—Approving revised location C.P.R. Lacombe Easterly Branch from a point in S.E. ¼ Sec. 2[illegible], Tp. [illegible], R. 12, W. 4 M., mileage [illegible] to a point in S.E. ¼ Sec. [illegible], Tp. [illegible], R. [illegible], W. 4 M., mileage 146.1[illegible], Alberta.

17593—September 26—Approving replacement of span, bridge 18.9, on the Elora Subdivision of C.P.R. (Plan No. 40504).

17594—September 25—Authorizing C.L.O. & W. (C.P.R.) to connect with K. & P. Ry., at Parham Station, Lot 25, Con. 1, Tp. of Hichinbrooke, Co. Frontenac, Ont., mileage 24.8 from Glen Tay.

17595—September 25—Authorizing C.L.O. & W. (C.P.R.) to construct bridge No. [illegible] over public road.

17596—September 25—Authorizing C.L.O. & W. to construct across 4 highways, mileage [illegible] to mileage [illegible], from Glen Tay.

17597—September 26—Approving revised location G.T.P. Branch Lines Co., Calgary-Boundary Branch from West Line, N.E. ¼ Sec. 12, Tp. 13, R. [illegible] to [illegible] N.W. ¼ Sec. [illegible], Tp. 11, R. [illegible], W. 4 M., mileage 81.41 [illegible] Dist. South Alta.

17598—September 28—Authorizing G.T.R. to reconstruct bridge No. 303 over [illegible] River, mile post [illegible], 13th Dist. Northern Division.

17599—September [illegible]—Approving revised location G.T.R. siding to premises of Western Foundry Co., Ltd., Wingham, Ont.

17600—September [illegible]—Authorizing G.T.R. to reconstruct three bridges [illegible] at mile post [illegible], 12th Dist. at Rockwood [illegible] 13th Dist. at [illegible], and mile post [illegible], 4th Dist. [illegible] Province of Ontario.

17601—September 26—Authorizing C.N.O.R. to construct across public road, Lot 44, Con. 1, Tp. Camden, Co. Addington, Ont., by means of overhead structure.

17602—September [illegible]—Authorizing Alberta Interurban Ry. Co. to construct [illegible] of G.T.P. Branch Lines Co., [illegible] Calgary Branch, [illegible] by means of overhead crossing.

17603—September [illegible]—Authorizing Alberta Interurban Ry. Co. to cross [illegible] C.P.R. Langdon Branch, [illegible], Tp. [illegible], R. [illegible], W. 4 M., by [illegible]

17615—September 25—Extending, until the 15th December, 1912, the time within which the G.T.R. complete bridge across Lachine Road at Rockfield, Que.

17616—September 26—Authorizing C.N.R. to construct across public road between Secs. 28 and 27, Tp. 28, R. 6, W. 4 M., on its Goose Lake Extension.

17617—September 25—Approving G.T.P. Ry. station site at Miniota, Sec. [illegible], Tp. 14, R. [illegible], W. 1st M.

17618—September 25—Refusing application G.T.P. Ry. for authority to construct wye track at mileage 29 west of Yellowhead Pass.

17619—September 25—Directing that joint freight rates to be charged by C.P.R., C.N.R., and G.T.P., on lumber, in carloads, between Port Arthur and Fort William, Ont., and points on Lake Superior Branch of G.T.P. be not higher than 1c. per 100 lbs., over rates of G.T.P. between Westfort, Ont., and said Lake Superior Branch points.

17620—September 2[illegible]—Authorizing Central Vermont Ry. to reconstruct bridge across Yamaska River at or near town of Farnham, Que.

17621—September [illegible]—Authorizing Bay of Quinte Ry. to revise grade of line across 2 highways in Tp. Portland, Co. of Frontenac, Ont.

17622—September 30—Authorizing Heaps Brick Co., Ltd., to cross tracks of Western Canada Power Co., Ltd., at Ruskin, B.C.

17623—October 1—Directing that the Dominion and Canadian Express Companies' delivery limits in city of Fredericton, N.B., be enclosed by River St. John, between Lansdowne St. and Odell Ave., Waterloo Row from south end of Ketchum's bridge, Lansdowne St., University Ave., Canadian Pacific Ry. to station; Victoria St. from Carleton St., Smythe St., Saunders St., and Odell Ave., to River.

17624—October 1—Directing that the Dominion Express Company's delivery limits in town of Rouleau, Sask., be enclosed by Wetmore St., from Railway Ave., Knox Ave., Brownlee St., and Railway Ave., to starting point.

17625—September 26—Authorizing C.N.O.R. to construct across 2 highways, mileage 221.09 and mileage 224.54, Tp. Ferris, and District of Nipissing.

17626—October 2—Authorizing Esquimalt & Nanaimo Ry. to construct industrial spur from point on its railway near intersection of Telegraph and Store Sts., Victoria, B.C., thence in southwesterly direction across Telegraph and Store Sts., and across lands of the Swift Canadian Co., Ltd., being Lot 125, on S.W. corner Telegraph and Store Sts.

17627—September 23—Authorizing C.N.O.R. to construct bridge across Humber River, Tp. York, Co. York, mileage 6.32, west of Toronto.

17628—September 30—Authorizing C.N. Montreal Tunnel & Terminal Co., Ltd., to cross tracks of the Jacques-Cartier and Union Ry. Co., near Jacques-Cartier Junction, Que.

17629—September 28—Certifying that correction, as shown on plan and book of reference, dated September 12th, 1912, of revised location of C.L.O. & W. (C.P.R.) across the mill pond, town of Bowmanville, Co. Durham, Ont., be allowed.

TENDERS CALLED FOR

TOWN OF DUNNVILLE, ONT.

Board of Waterworks Commissioners.

Tenders will be received by the undersigned up to 6 p.m. on the 21st October, 1912, for 9,640 feet (approx.) of four and six-inch water mains, together with the necessary valves, hydrants, and specials.

Specifications and instructions to bidders may be had from the undersigned.

The Board does not bind itself to accept any tender.

ALAN MAIR JACKSON,
Oct. 7th, 1912. Superintendent.

For further Tenders see page 76.

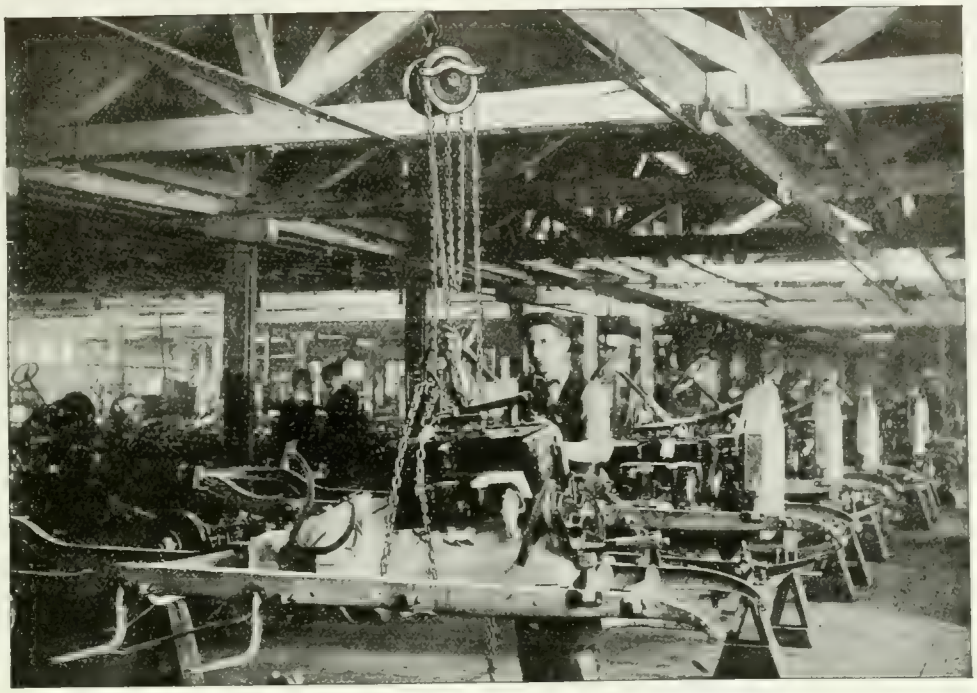
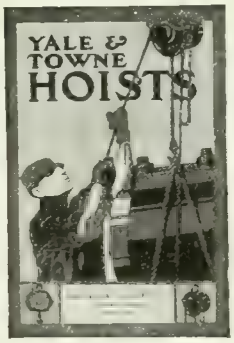
THE TRIPLEX BLOCK



Placing engine in chassis with a half-ton Triplex Block.

A 100-page Book on Hoists



Practical engineers are all agreed that radical cuts in cost can be brought about by solving hoisting problems. Such problems are not solved satisfactorily by heavy cranes which do not give continuous service. A load that is waiting to be moved is costing money just as much as a load which is taking a gang of workmen to move.

A hoisting problem is not solved until each workman can readily lift and transport any load, single handed, that comes to him.

The new Book of Hoists shows examples of hand and power hoisting and overhead apparatus for conveying in model plants, here and abroad. The information is the most complete we have ever published. We will be glad to send a copy free on request.

Triplex Blocks; **16 Sizes:** One-quarter of a ton to forty tons. **300 Active Stocks** all over the United States. **Every Block Tested to 50% Overload.**

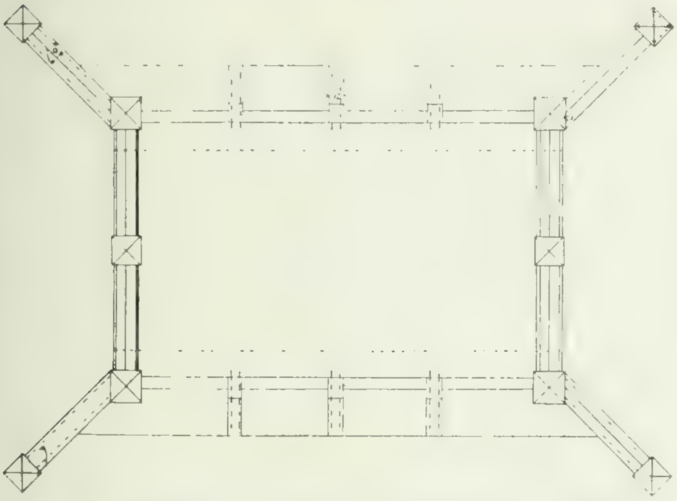
The Canadian Engineer

An Engineering Weekly

REINFORCED CONCRETE ARCH, NORTH TORONTO

By E. A. JAMES, B.A.Sc.*

For the last year the wooden bridge which carried Albertus Avenue across a creek about a quarter of a mile west of Yonge Street has been in an unfit condition for traffic. As this road leads only to land that is just being opened up, the necessity for a bridge has not been felt.

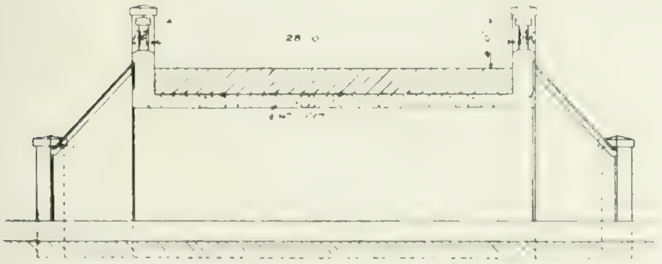


Plan of Bridge for Albertus Avenue, North Toronto.

In the spring of this year, however, it was decided to erect a permanent bridge and one which would harmonize with the surroundings.

The situation is a ravine about 20 feet deep and 150 feet wide. Through the ravine a stream flows in the fall and in winter freezes and forms an ice jam on a small scale. In the summer the bed is quite dry.

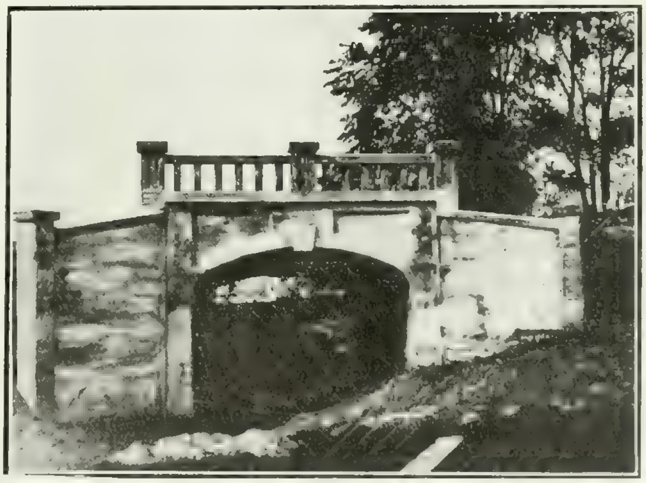
The type of bridge decided on was a reinforced concrete arch on abutment walls and with wing walls to hold back the fill. The span is 14 feet and the height from bed of creek to soffit is 12 feet. The clear width between parapets is 28 feet.



Longitudinal Section Through Bridge.

The foundations were put in during wet weather and are 4 feet below datum (the bed of the stream). The material is a compact sandy clay. The original foundation designs were for a slab foundation 1 foot below datum, but on excavating this did not give a good enough bottom. A 2-foot bed of concrete was placed in the excavation and the foundation placed in this. The material was dumped down in barrow loads from a platform 10 feet high, on which the mixing was done. As the foundation was very soft, the concrete was put down as dry as possible. The concrete was mixed by hand in about ¼ yard batches, the proportions for the foundations being 1 of cement to 7 of pit gravel.

The forms were started about datum level, and consisted mostly of 2-inch by 4-inch uprights with 1 inch planed tongued and grooved boarding. The forms were strutted from the outside with 3-inch by 8-inch lumber, also tied together with wire spaced about 2 feet in either direction. The front forms of the abutment were carried up to springing level and also the uprights of the back, but the boards in the rear were put in as the concrete rose.



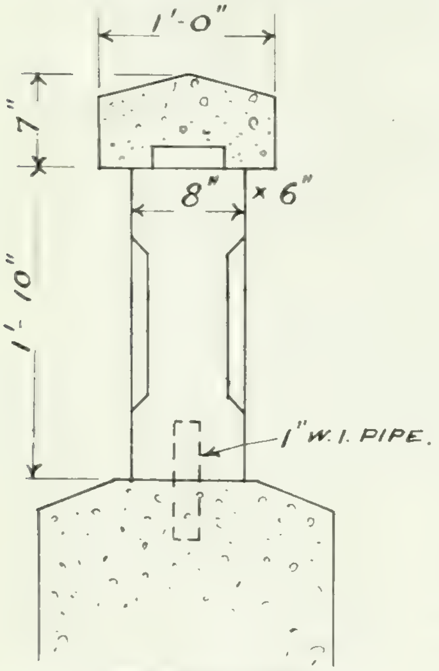
View of Bridge on Albertus Avenue, North Toronto.

The reinforcement in the abutments is ½-inch twisted steel, spaced at 24-inch centres for the vertical rods and 12-inch centres for the horizontal rods. In the wings the reinforcement was ½-inch twisted rods at 12-inch centres both horizontally and vertically. The reinforcement for the wings was ½-inch twisted bars at 12-inch centres both horizontally and vertically tying into the abutments. As the space between the steel in the abutments and the forms was only 2 inches by 3 inches, it was found rather difficult to pack and work the concrete at the face, but good results were secured

---

* Consulting Engineer to Town of North Toronto.

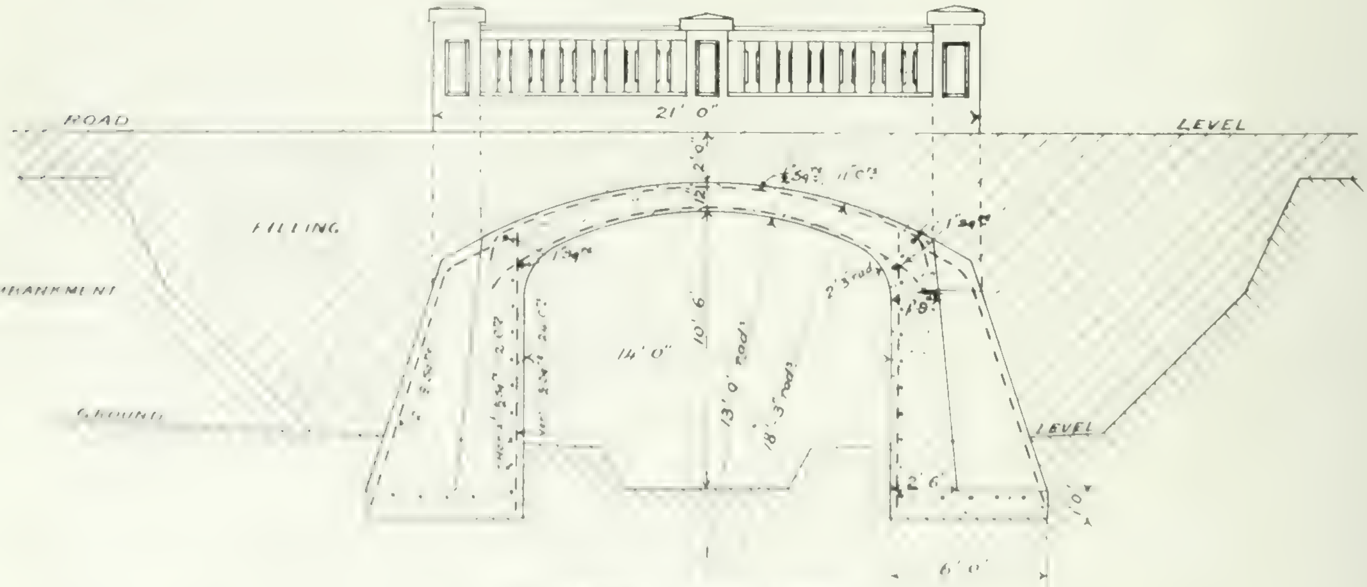
When the abutments were about 4 feet above datum, cracks began to show. These cracks occurred especially where a mark had been made in the surface as with a hoe, or a footprint. As it was thought that the rather heavy rains, experienced about this time, might have softened the ends of the abutments, levels were taken every other day for a while, but these did not indicate enough settlement to account for the cracks.



Detail of Hand Rail.

Tests made of each car load of cement delivered on the work showed good results as to soundness and setting powers. The use of wet concrete was stopped and when a drier mix was used an improvement occurred. The use of gravel without any stone was probably a contributory cause.

The abutments were carried up to within 6 inches of the springing and then the ribs for the centering were put into place. There were ten ribs, made up from 2-inch by 6-inch



Cross Section Through Bridge.

timbers. No wedges were used. The lagging was 2-inch planed lumber, and was covered with tar paper. The arch was put in all in one operation.

The forms for the posts at the end of the railing had about [illegible] with 1-inch pipe placed to bond with the railing of concrete. The railings on the parapets were cast separately with [illegible] at one end such as would [illegible] the railing posts. [illegible] were set up [illegible] and [illegible] [illegible] to [illegible] [illegible] such [illegible] small [illegible] of [illegible] board with the bottoms just at the level of the sills of the spandrel walls. Another sill was then formed over the tops and when these set, the railings were securely held.

The forms for the outside walls were removed in one week and the arch forms in four weeks. The face was filled with a grout of 1 cement to 1 sand and all rough places filled with mortar.

The backing was put in by wheel scrapers.

The cost of the construction work when reduced to unit prices were as follows:

Material Delivered at the Works.

Stone, 2 in., per cubic yard	$ 2.30
Gravel, per cubic yard	2.10
Steel, per lb.	.045
Lumber for forms, per M.	38.00

Labor for Work.

Concrete, per cubic yard	$ 1.10
Forms, per cubic yard of concrete	1.25
Earth excavation, per cubic yard	.29

◆

NIPISSING CENTRAL RAILWAY.

The Nipissing Central Railway Company was incorporated under the Dominion Charter in the year 1907. The following is abstracted from the annual report of the chief engineer: It owns and operates a line of electric railway between Cobalt and Haileybury, having a total length of 5.15 miles. The railway is located, in part, on its own right-of-way, and elsewhere on the streets and highways of the Township of Bucke, and the Town of Haileybury. Agreements were entered into with each of the above municipalities, providing for the operation of an electric street railway.

The T. & N.O. Railway Commission having purchased the capital stock of the Nipissing Central Railway on June [illegible], the Nipissing Central Railway was placed under the management of the general officers of the T. & N.O. Railway. The affairs of the two railways are kept quite separate. There is a local Superintendent and cashier in charge of the Nipissing Central Railway, reporting to the appropriate officials of the T. & N.O. Railway.

Route.—The Cobalt terminus is at the foot of Argentite Street. The location is in a general north-easterly direction from Cobalt, on private right-of-way on the west side of the

T. & N.O. right-of-way, crossing the latter by an overhead crossing at Argentite, thence along the Cross Lake Road to the Townsite of North Cobalt, thence along King Street, Lakeview Avenue, and Main Street, thence across private right-of-way to Georgina Avenue, Haileybury, thence northerly along Georgina Avenue to Blackwell Street, easterly along Blackwell Street to Ferguson Avenue, northerly along Ferguson Avenue to Browning Street.

Service.—A regular half-hour service is maintained between Cobalt and Haileybury from 6 a.m. to 11 p.m. At rush hours and on holidays the service is increased as may be necessary to accommodate the traffic.

Rolling Stock.—The following rolling stock was taken over with the Nipissing Central Railway:

3 42-foot double truck closed passenger coaches, each equipped with 40 h.p. motors, air and hand brakes, air whistle, arc headlamps, pilots, snow flangers, traffic recorders, and all necessary appliances necessary for an up-to-date electric trolley system.

1 combination baggage and passenger car, equipped with appliances similar to passenger coaches referred to above.

2 trailers of the same composition as the coaches, but having, of course, no motors.

1 four-wheel van.

2 thirty-foot flat cars.

1 small industrial standard gauge locomotive.

The locomotive referred to being practically of no use to the Nipissing Central Railway, was disposed of to advantage, brought down to North Bay Junction, where it is at present undergoing a general repair in the T. & N.O. shops, at the request of the firm purchasing same.

The other equipment referred to is all at present in very good condition, some slight repairs having been made to the passenger coaches; air brakes inspected and necessary overhauling done during the months of September and October.

Buildings.—The only buildings in connection with the Nipissing Central Railway are the car barn, which is situated between Haileybury and North Cobalt, and an office and waiting room. The car barn is a galvanized iron structure 150 feet by 60 feet, being 20 feet high at the eaves. A single track runs into this building which branches off into three, one track running over an inspection pit. Considerable repairs were made during the summer months to the roof of barn, rendering it in good serviceable condition.

The sub-station located in car barns consists of two motor generator sets of 400 h.p. and 200 h.p. capacity respectively.

Transmission System.—Power is obtained from the British Canadian Power Company's sub-station at Cobalt. A 2,200-volt transmission line connects the Power Company's sub-station with the Nipissing Central Railway sub-station in the car barns at North Cobalt. Another transmission line connected the sub-station at North Cobalt with power plant of the High Falls Power Company, but this transmission line is not in use, as the High Falls Company is not operating.

The trolley wire is No. 000 grooved section and, having no feeders, carries all the current used. The overhead system is composed of span wire type, with the exception of eighteen pole lengths of bracket type.

Roadbed.—The roadbed was never properly ballasted and some heavy expenditures for ballast will be necessary in the coming year.

Extensions.—An extension of the Nipissing Central Railway from its present terminus, Browning Street, Haileybury, to New Liskeard, also a freight spur to the Government wharf and Foster's Mill, are under consideration. Surveys for these have been completed, and negotiations are now being carried on for the necessary franchises from the towns of Haileybury and New Liskeard and Township of Bucke.

CANADIAN ROAD SYSTEMS.*

By W. A. McLean.†

Efficient system and organization form the key to highway improvement. If the laws and plan of administration are properly arranged, all details will be taken care of. If the system is well designed, ratepayers and citizens will have at their service a powerful machine, perfect in all its parts, that will produce finished highways, durably built, adapted to the service they are to perform, well maintained, and at a minimum cost.

System implies an effective means of procuring necessary funds, a fair and just method of distributing the cost, a general management based on good business principles, the application of engineering skill to design, and construction carried on with the best utilization of power and labor.

The creation of a thoroughly efficient system of highway construction and maintenance is a task which, in Canada and the Canadian Provinces, is being actively considered and dealt with. While some satisfactory progress has been made, measures to the present time have been those of the formative stage. Evolution rather than revolution has been the history of legislation in countries of the north, and highways systems and measures of Canada are following that general rule.

The Canadian form of government is similar to that of the United States in some respects. Canada is a union of Provinces, with a Federal administration at Ottawa, just as the United States is a federation of States with seat of government at Washington. Each of the nine Provinces has its own legislature, as have each of the States; and the provinces are again divided into local municipalities—the rural being townships and counties, and the urban are villages, towns and cities—but as in the States, local government varies in the different provinces.

The Canadian Constitution, "The British North America Act," defines the powers and jurisdiction of the Provincial and those of the Federal or Dominion Government. Under that Act legislation respecting public roads and municipal organization is within the authority of the Provinces, although the Dominion Government has power to subsidize road construction. The tendency in each Province (with certain exceptions) until recently has been to regard the opening and grading of roads in new territory as a Provincial function, while the real improvement and construction of these roads is a municipal function as settlement becomes established and municipal organization is created.

Canada has a geographical backbone, a rocky mineral region about the centre of the continent, extending northerly from Lake Superior to Hudson's Bay. West of Lake Superior the four Provinces of Manitoba, Saskatchewan, Alberta, and British Columbia are comparatively new, having been developed since the construction of the first Canadian transcontinental railway, the Canadian Pacific Railway, in 1886. East of the Lake Superior region are the old Provinces of Ontario, Quebec, New Brunswick, Nova Scotia, and Prince Edward Island.

British Columbia.—British Columbia, on the Pacific coast, is traversed by the Rocky Mountains, and municipal organization is, therefore, interrupted. In consequence, the Provincial Government has always contributed largely to road-building. At the present time a special fund is being spent on the construction of trunk roads at the rate of $5,000,000 annually under the direction of the Department of Public Works. Stone for macadam roads is plentiful, but the grading of mountain highways is expensive. The trunk roads now being built have an important scenic value, and upon completion will attract many tourists. In the past ten years approximately $15,000,000 has been spent by the Province on roads and bridges, but the expenditure of an equal amount in the three years, 1912-14, is now outlined.

---

* Paper delivered at American Road Congress, Atlantic City, October 5th, 1912.

† Chief Engineer of Highways for Ontario, Canada.

Saskatchewan and Alberta.—Saskatchewan and Alberta, occupying the prairie country north of Montana and North Dakota, were granted provincial organization in 1905, and are in a pioneer stage of development. Earth roads, with bridges, are the present need, and very little has been done toward good broken stone or gravel roads. Each of these Provinces has a Provincial Highway Department, however, and is drawing largely on its resources for road expenditure. The Provincial Governments in each case are grading and bridging the main roads. As fast as settlement permits, three or four townships are organized into Local Improvement Districts, with councils, to expend money raised by local taxation. In the case of Saskatchewan, an annual provincial appropriation (in 1910, the sum of $60,000) was set aside to be drawn upon by the municipalities under a plan of Provincial aid. The chief Provincial expenditure in these Provinces is applied, however, to trunk highways by the Provincial Highway Departments through their own foremen. Steel and wooden bridges are also erected by permanent "bridge gangs." The Provincial Departments also carry on educational work. In Saskatchewan a special appropriation of $5,000,000 for trunk roads was made the last session of the Legislature, of which $1,500,000 will be spent this year, in addition to the usual appropriation of $400,000 from current revenue. In Alberta a special grant of $1,000,000 was made this year for a central north and south trunk road in addition to the usual sum of $250,000 from current revenue.

Manitoba.—Manitoba has for several years had a Provincial Highway Commissioner, whose duties were largely educational. At the last session of the Legislature (January, 1912), two important Acts were passed. One of these, the Act Respecting Provincial Highways, set aside $200,000 annually for Provincial aid to main roads. Townships are permitted to lay out a special system of main highways and this plan, with specifications, are to be submitted to the Provincial Highway Department. If approved by the Provincial authorities, the township may issue thirty-year debentures and proceed with the work, receiving a grant of two-thirds of the expenditure from the Province. In this way it is expected that a serviceable system of Provincial roads will be constructed.

The other Act, known as "The Good Roads Act," is one which relates to minor roads, and does not provide Provincial aid; but requires any township undertaking the improvement of these roads to submit the plans to the Provincial authorities, and when approved the township may issue fifty-year debentures to meet the cost, which debentures may be guaranteed or purchased by the Provincial Government. The work done under this Act is also subject to the inspection and approval of the Provincial Highways Commissioner.

Ontario. Ontario is, physically, in two parts—old Ontario settled for over a century, and with complete municipal organizations; and new, or Northern Ontario, now being opened for settlement. In New Ontario the Provincial Government is this year spending about $[illegible] on colonization roads, and grading the road allowances and [illegible] the bridges.

In Old Ontario, the local municipalities are spending yearly about [illegible] in statute labor and [illegible] in cash. A large proportion of the latter [illegible] through [illegible] and [illegible].

The "Highway Improvement Act" of Ontario [illegible] county councils (composed of [illegible] of the local municipalities composing the county) are empowered to pass a by-law assuming for construction and maintenance a system of main highways.

To this work the Provincial Government contributes one-third of the cost of construction as the work progresses. The Provincial Highway Department fixes certain regulations as to construction and management, inspects from time to time, and co-operates with the municipalities to obtain good results, but the active control is vested in the county councils through their own county engineer.

This Act has been in operation for eleven years, and the annual outlay under it is steadily increasing. In 1911 the total expenditure was $711,000, of which the Province contributed one-third.

This Act is largely educational in its aim, but at the same time is producing much excellent work at a low cost. The educational effect has several features:—

(1) It brings about an increasingly high standard of road construction, which teaches the public what good roads are and how they should be built.

(2) It instructs county councillors in road construction and impresses upon them the principles of good organization.

(3) The roads and organization become models which are observed and imitated by the township councils, so that all roads are affected.

(4) It enables the Provincial Highway Department to prescribe good principles, and the results of investigation, in an effective way.

The Ontario Highway Department is also constructing, at various points, model roads at the sole cost of the Province, or with a partial contribution from the municipality in which the road is built.

Quebec.—The Province of Quebec has been extremely active in the matter of road construction, and has adopted several measures of a progressive character:—

(1) The Province loans road-making machinery to municipalities making request, and has ten complete outfits for this purpose.

(2) Grants are made to local municipalities which dispense with the labor tax, and build an extent of durable gravel or stone road. Nearly 600 out of a total of 1,000 townships are this year taking advantage of the measure.

(3) The sum of $10,000,000, borrowed under 41-year bonds, has been set aside for main highways. Municipalities may, for their construction, draw upon that sum, and are only required to meet one-half the interest (2 per cent.) on the moneys so used for the term of the bond issue, the Province meeting the sinking fund and remainder of the interest.

(4) Three Provincial highways, aggregating 350 miles in length, are now under construction. To this work the local municipalities pay $1,000 per mile, and the Provincial Government contributes the remainder.

New Brunswick.—New Brunswick has not as yet developed a broad policy leading to permanent road construction, but the Provincial Engineer, by means of a contribution to county and parish construction, is enabled to bring technical instruction to bear on the work. The Province appropriated $[illegible] annually for this purpose.

Nova Scotia.—Nova Scotia is very actively canvassing the road question. The Province is subdivided by county organization only, and the counties levy a statute labor tax amounting to about $[illegible] annually. But the Province spends about $[illegible] annually on road construction through an active and well-organized Provincial Highway Department. The Province constructs all bridges costing over $500.

Prince Edward Island.—Prince Edward Island, the smallest but one of the most fertile of the Provinces, has an isolated position in the Gulf of St. Lawrence. Except in the case of two cities, there is no municipal organization.

and the Provincial Government exercises direct control of all the roads. The Province is divided into thirty-eight districts, each having about 100 miles of road, and a road overseer is in charge of the work in each. The Province spends about $32,000 annually in maintaining earth roads, and very little macadamizing has yet been done.

The Federal Government.—The Dominion Government at the last session introduced a bill to provide for grants to Provinces to aid in highway improvement to be distributed according to population, and also to provide for direct expenditure on construction by the Dominion. The bill passed the House of Commons, but the Senate, while approving of subsidies, objected to the Dominion Government making direct expenditures. The amendments of the Senate were not acceptable to the Government, the bill was not re-introduced into House of Commons, and the measure thus failed to become law.

Summary.—Canadian road systems have been, to the present, without enormous Government appropriations or other spectacular features, and construction, as a rule, has been of a comparatively inexpensive type. Rather it is sought to build as substantially as possible for present requirements, and to establish efficient systems of maintenance that will thicken and widen the road crust as traffic requires. Such a policy will, we believe, lead to the more rapid and economical extension of good roads without creating large public debts that will embarrass the future.

Summarizing the situation briefly, Canadian Provinces have about 250,000 miles of public highways. Each of the Provincial Governments contribute directly to road improvement, generally in the form of Provincial grants, where municipal organization permits. Such grants, rightly directed, help the people to help themselves, combine all energy into one effort, and have a highly educative value. Each of the Provinces has a Highway Department for building roads with which the educational object is more or less associated. The Canadian Highway Association is now carrying on an extensive propaganda to construct a road 4,000 miles in length from Halifax to Victoria while the Ontario Good Roads Association, the Manitoba Good Roads Association, and other organizations are doing much to form public opinion. As a result of the interest created, Provincial appropriations are now being made in millions where they were formerly made in thousands. This year the total Provincial expenditures, apart from municipal levies, will amount to $10,000,000. Canada has developed splendid railway and waterway systems, but it is evident that an era of common highway building is being entered upon, that will connect the trunk lines of transportation with the homes and daily life of the people.

◆

DURABILITY OF PORTLAND STONE.

"Experiments on the Weathering of Portland Stone," was the subject of a paper by Dr. J. S. Owens, before the Engineering Section of the British Association. The investigation was initiated by Dr. Des Voeux and was being made for the Coal Smoke Abatement Society. Its object was to find the connection between smoke and the well-known deterioration, by sulphating, of stones containing a large proportion of calcium or magnesium carbonate, when exposed to city air.

The stones were subjected to the following conditions for periods varying from 105 to 687 days: (a) Broken without exposure; (b) broken after exposure to natural conditions out of doors in the country and in London; (c) broken after having been kept indoors in the country and in London; (d) broken after having been exposed, while embedded in soot, to country and London air. The experiments were still in progress.

THE USE OF MOTOR TRUCKS IN ROAD CONSTRUCTION AND MAINTENANCE.

The use of motor trucks has rapidly increased during the last year. In a recent issue of the Concrete-Cement Age, Mr. Rollin W. Hutchinson, Jr., gives some data and costs regarding their use on road construction and maintenance. He says that those who have made a careful study of economic road maintenance have generally conceded that the neglect on the part of cities, towns and townships promptly to repair their roads has brought about an excessive maintenance cost. It is generally accepted as a truism that $50,000,000 is being spent for road building in the United States every year and not 1 per cent. of this is expended for their maintenance.

If two men with the proper equipment were kept constantly employed going over the roads in their territory equipped with materials and tools with which to properly repair trifling defects, the annual expense of such repair work would be considerably less than is now the case with the plan of periodical repair work.

From all information obtainable, it appears that a new piece of road is generally allowed to take care of itself for the first year or two, and at the end of that time the neglect properly to repair what were originally trifling defects has allowed the road to get in frightful disrepair, requiring a very considerable sum to restore it to its former condition.

Very many miles of road could be taken care of by a motor truck operating daily and covering all of the roads in the care of the city or county where it is to work. This truck could be provided with changeable bodies, one of these bodies to be of box construction to carry sand, gravel, crushed stone and top dressing as might be required; at other times tar kettle and material for building roadside fires. The other body could be for water for sprinkling.

A small hole or rut worn in a road, if neglected, will have its sides gradually torn down by continuous traffic and develop into a large hole, requiring the expenditure of a considerable sum to effect proper repairs.

With the advent of the motor truck and automobile it is believed that the business men in every community have come to realize the importance and economy in maintaining good roads.

Depreciation on all vehicles, both horse-drawn and motor-driven, is very considerable where poor roads exist, or where good roads are allowed to get in bad condition for the want of prompt repair.

A manufacturer in advertising the hill-climbing ability of its pleasure cars uses the winding road ascending Eagle Rock Mountain in the Oranges, New Jersey, as a test climb, and many a car has attempted the ascent of this mountain and faded pantingly away before reaching the summit of a grade which runs from 15% to 17%.

Knowing these facts one would hardly look here for a heavy vehicle of any kind operating otherwise than down hill. Modern transportation equipment must however, meet and cope with local conditions, surmounting grades and other difficulties.

The Joseph Murphy Sons C., Hoboken, N.J., employ at Eagle Rock quarry a 7-ton Mack truck with dumping body, on this steep mountain road, hauling broken stone from the Eagle Rock quarry to various points on both sides of the mountain.

The quarry is three-quarters of the distance up the road from the base of the mountain, at a point where the road verges into an abrupt curve, which adds to the difficulty of the ascent, which is here at its steepest.

In the summer of 1911 the truck averaged 55 miles in nine trips a day, hauling 63 tons, or more than five times the work possible with a team of horses making four trips, carrying three tons per trip, or twelve tons in the same time.

There are a number of stone quarries in the vicinity of Baltimore which could use motor trucks to good advantage and with considerable saving. MacMahon Bros., Mt. Washington, with 5-ton and 4-ton Mack trucks, with automatic dumping bodies, and the Schwind Quarry Co., with a 3-ton Packard, are using the motor truck for hauling broken stone for road building. In order to show what could be done in this line, Messrs. Hook and Ford, engineers for MacMahon Bros., ran a week's test with a 5-ton Mack truck with automatic dumping body in competition with a four-mule-team wagon, hauling broken stone for road building from the Dickeyville quarry with the results given below. The truck had to make ten miles to a round trip, as against nine for the team, on account of having to go a mile out of the way on the trip from the quarry in order to avoid a bridge which was too weak to carry when loaded. One mile of the trip loaded was up a 14% grade. The average amount of gasoline consumed was 29 gallons; average amount of oil consumed, 2 gallons; average working hours, 10; average time loading, 3 minutes; average time unloading, 10 minutes; total load carried, 60,000 pounds; number of trips, 6; total mileage, 60 miles. There were three rainy days in the test period, so that most of the time the roads were soft and in bad condition.

Another advantage in the use of the truck is in the spreading of the stone. It took the truck ten minutes to spread the stone as shown, which the contractor stated was done better than could be done by hand and saved the labor of two men working with shovels for one hour. This spreading was regulated by opening the tail board the proper distance and thus letting the truck travel slowly over the road with the body in an inclined position. The results of the comparative tests of motor trucks and mule equipment as made are:

4-Mule-Team Hauling 4½ Tons Per Day 27 Miles.

First Cost.

4 Mules at $325.00 each	$1,300.00
Harness	75.00
Wagon	250.00
	$1,625.00

Mules.

Interest on ½ investment at 6%		$ 48.75
Insurance on team		32.50
Depreciation 20%		325.00
Fixed charges per day (assuming 225 working days per year)		1.85
Wages per day	$1.84	
Feeding at 60c. per head	2.40	
Stable man	0.25	
[illegible]	[illegible]	
[illegible]	[illegible]	
*[illegible]	[illegible]	
Total daily operating cost		$6.18
Fixed charges per day		1.85
Total charges per day		$8.03

5-Ton Dump Truck Hauling 5 Tons Per Day 60 Miles.

First Cost.

Truck	$[illegible]

*[illegible]

Truck.

Interest on ½ investment at 6%		$159.00
Insurance on truck 2½% on 80% of ⅓ value		53.00
Depreciation on truck (not including tires)		480.00
Fixed charges per year		$692.00
Fixed charges per day		3.07
Wages per day	$2.50	
Maint. 4½c. per mile	2.70	
Tires 6c. per mile	3.00	
Gasoline 4c.	2.40	
Oil	0.60	
Total daily operating cost		$11.80
Fixed charges per day		3.07
Total charges per day		$14.87

4-Mule team hauls 13¼ x 4¼ = 57.37 ton miles per day = 13.9c. per ton mile.

5-ton truck hauls 5 x 30 = 150 ton miles per day = 9.9c. per ton mile or a saving of 4c. per ton mile or $6.00 per day.

◆

THE TREATMENT OF EFFLUENTS FROM TRICKLING FILTERS.

The effluents from two trickling filters at the Lawrence Experiment Station of the Massachusetts State Board of Health are passed through a settling tank holding about 5½ hours' flow and are then applied at the rate of 10,000,000 gal. per acre daily to a filter having 2 feet of sand of an effective size of 0.23 millimeter. This filter was operated continuously during 1910, much like continuous water filters, except that when clogged the whole body of sand in the filter was washed in place by an upward current of water from below. The filter was washed 68 times during the year, the average quantity of water filtered between washings being about 39,000,000 gal. per acre.

The results obtained with this filter and settling tank furnish an interesting illustration of the future purification of trickling filter effluents by natural means, according to a report by Messrs. H. W. Clark and S. DeM. Gage. The nearly stable worked-over suspended matters coming from the trickling filters settle out readily in the settling tank, but these suspended matters were capable of further fermentation and disintegration, as is shown by the fact that during the warm months, in spite of the frequent removal of sludge, there was some floating scum on the tank, with a certain amount of gas formation. This fermentation must not be confused with putrefaction however, as no appreciable odors were produced. The clarification begun in the settling tank was completed in the filter, and the final effluent never contained more than a slight turbidity.

The purification process going on in the settling tank and in the filter was the reverse of nitrification, the nitrates serving as the source of oxygen for further oxidation of the soluble matters. This is evident by the reduction in the amount of nitrates and increase in the nitrates and free ammonia in the applied effluents in their passage through the settling tank and through the filter. This was in a measure a retrograde process, but is undoubtedly the process taking place when such trickling filter effluents flow into water low in dissolved oxygen. The amount of nitrates remaining in the effluent, and the fact that this effluent always contained an appreciable amount of dissolved oxygen, indicated a complete stability at all times, and this fact was confirmed by negative putrescibility tests throughout the year.

HIGHWAY ENGINEERING EDUCATION.*

By Arthur H. Blanchard, M.Am.Soc.C.E.†

The educational training of the engineer who may enter that branch of civil engineering devoted to the economics, construction and maintenance of highways should be considered from two standpoints: first, the essentials, which, from an educational point of view, are considered as prerequisite to a successful career in highway engineering; and, second, practical methods of securing this training under American conditions.

The American youth who has expressed the desire to enter the profession of engineering has various channels open to him. The usual course followed is to enroll in one of the four-year engineering courses designated as civil engineering, mechanical engineering, electrical engineering, chemical engineering or mining engineering. There are, however, notable deviations. Several institutions and some engineers advocate a broader training for the engineering profession than is possible in the ordinary four-year course, and in fact believe that the profession of engineering demands the same type of training as is now universally recognized as desirable for men entering the legal or medical profession.

Usually the American boy, in entering on a technical career, has not fully made up his mind as to the particular field in which he is most interested. In the four year courses he has in some cases one, and in others two years in which to make up his mind as to which of the five general branches of engineering referred to above he wishes to enter. It is self-evident that the ideal training is one which will prepare a student upon graduation to enter any one of the numerous fields of engineering. At least it is possible that a comparatively wide field of activities will be open to a man whichever one of the above courses he takes in the technical school.

Having these general facts in mind, attention will now be riveted upon the situation which confronts the young man who may be one of our future highway engineers. Let us suppose, for example, that he has decided to devote four years to securing a technical education and that there is offered to him the four-year course in civil engineering and a four-year course designated as highway engineering. Which course should he take? The evils of over-specialization in the undergraduate engineering course have been fully discussed in the Society for the Promotion of Engineering Education. Suffice it to say in this discussion before the general public interested in highway improvement that the graduate of the civil engineering course on the one hand has before him a large field of activities for all of which he is equally well equipped. For instance, he may enter the field of structural engineering, sanitary engineering, railroad engineering, geodetic engineering, hydraulic engineering, highway engineering, irrigation engineering and in many cases mechanical, electrical and mining engineering. On the other hand, a graduate from a so-called four years course in highway engineering has, if the course is made up of the subjects which the title implies, only a limited field in which he considers that he is particularly proficient.

The consensus of opinion of eminent highway engineers and educators is to the effect that the highway engineer of the future requires the broad foundation which the four-year course in civil engineering gives. A knowledge of practically all of the subjects included is found of value in the manifold duties imposed in the various positions which he may occupy in the service of municipalities, states, counties, towns, estates, contractors' organizations, consulting engineers' offices, and manufacturing companies.

In the consideration of the training received and the subjects covered in the four-year course in civil engineering relating especially to highway engineering, it is of interest to note the present status of highway engineering in the civil engineering courses of American universities and technical institutions. An examination of the latest catalogues received from ninety-two institutions in the United States offering courses in civil engineering showed that seventy-eight included a text-book-lecture course in highway engineering in the curriculum. The number of recitation-lecture hours in the various courses may be arranged approximately in the following groups: thirteen, 15 hours or less; twenty-eight, 30 hours; seventeen, 45 hours; six, 60 hours; six, 75 hours; three, 90 hours, three, 120 hours; one, 135 hours; and one, 165 hours. Fifteen give some instruction in laboratory work, while ten include special courses in highway surveying. In the case of institutions devoting over ninety hours to highway engineering, the general civil engineering course covers three years, while a highway option is taken in the fourth year. A comparison of the present status of highway engineering education, as outlined above, with the conditions described by Logan Waller Page in his valuable paper on "Highway Engineering," presented before the Society for the Promotion of Engineering Education in 1909, is certainly encouraging, especially when it is remembered that only three years have elapsed. In 1909, according to Mr. Page, fifty per cent. of the institutions investigated did not include a course on highways in the civil engineering curriculum, while it is noted that of the courses in ninety-two institutions examined by the speaker, eighty-five per cent. now give a course in highway engineering.

The importance of the subject of the economics, construction and maintenance of roads and pavements in the United States at the present time demands that more prominence should be given to the course in highway engineering in civil engineering curricula. Having in mind the various component parts which go to make up the curricula, it appears that a well-balanced civil engineering course under present conditions should contain a three-hour course of one year in length devoted to highway engineering.

In such a course lectures and text book work should cover the following topics: historical review of the construction of roads and pavements; preliminary investigations incident to construction; principles of surveying and mapping peculiar to highway work; design of highways; drainage and foundations; construction and maintenance of earth, sand clay, gravel and broken stone roads, including a consideration of the materials which enter into their construction; general consideration of bituminous materials as such and their use in the construction of bituminous surfaces, and bituminous macadam, bituminous concrete, sheet asphalt and asphalt block pavements; the construction and maintenance of wood block, stone block, brick and cement concrete pavements; dust prevention, street cleaning and snow removal; construction of car tracks and pipe systems; comparison of roads and pavements; construction of sidewalks, bridges and culverts; and a general treatment of economics, highway administration and highway legislation.

Laboratory work should be limited to what is sometimes called lecture demonstration work by the officers of instruction. In other words, although it is advisable that the methods of testing all kinds of bituminous and non-bituminous road materials should be brought to the attention of

---

[*] Presented before the American Road Congress at Atlantic City on October 3rd, 1912.

[†] Professor of Highway Engineering, Columbia University, New York City.

students in civil engineering by actual demonstrations in the laboratory or lecture room, it is not considered advisable to devote the time necessary for each student to run through complete tests as is done by students in the laboratories devoted to the testing of structural materials. In two to five afternoons all the fundamental tests employed in the examination of bituminous and non-bituminous road materials could be demonstrated before a group of from twenty-five to thirty men if the laboratory equipment was properly arranged and the work well planned out. Two to three afternoons would suffice if the testing of bituminous materials were covered in a course given by the department of chemistry. Unfortunately, at the present time very few instructors in chemistry are familiar with bituminous materials, hence the methods of testing will have to be worked up by civil engineering instructors. Eventually some of the time now given by the department of chemistry to carbon compounds or quantitative analysis in courses for civil engineering students can be profitably devoted to the chemistry of bituminous materials.

A limited number of inspection trips covering the economics of highway location, and the construction and maintenance of various types of roads and pavements will be of value.

The time devoted to road or street surveys in some institutions, in addition to the regular work in railroad surveying and general surveying, is of questionable merit. Although there are many problems in highway surveying which are different from those encountered in other branches of surveying, it is doubtful if it is necessary or expedient to use up valuable time on this work considering the number of subjects which it is necessary to include in a broad course in civil engineering. The speaker's experience with civil engineering graduates who have worked under him on highway work has led to the belief that a graduate in civil engineering, who has had a good course in railroad surveying and in railroad curves, together with a comprehensive course in highway engineering, as outlined above, is admirably equipped to occupy the minor positions in a field party on highway surveys. In these positions he may acquire, either through advanced study or special instruction, the information and practice necessary to occupy the position of chief of party and the higher positions in the highway department connected with the bureau of surveys. It is, however, advisable in certain instances, where practicable, to divide the time devoted to railroad surveying so that a highway survey outside built-up districts may be added to the course together with the preparation of plans, cross-sections and estimates.

In further consideration of the special training which will be of benefit to those entering the field of highway engineering, the educational plans which have been evolved to elevate the profession and to equip men thoroughly for this field of engineering work, foreign practice will be given consideration first.

Great Britain affords an illustration of one method by which well trained highway engineers may, under favorable circumstances, be secured. Fortunately for the British engineer, the position of highway work is much more permanent than in the United States. There are several reasons [illegible]. Among these may be mentioned the recognition by the British public that the principle of continuity in office of qualified engineers results generally in economical and efficient construction and maintenance of public works. Those American engineers who visited Great Britain at the time of the Second International Road Congress in 1910 will, without doubt, find the majority of the prominent highway engineers of England occupying the same positions of responsibility when they attend the Third International Road Congress to be held in London in 1913. This is not a long period, but could the same observation be made in regard to the personnel of many of our great state highway departments for a similar period? It should be stated, however, that the subordinate positions in the United States being, in many cases, under civil service regulation are more permanent than those effected by political exigencies. This condition of permanency of position of high officials in Great Britain means that it is possible for young men who are attracted to highway engineering to enter the department of some county or municipal engineer, and, proving capable, to acquire a valuable experience under the continued leadership of an able engineer. In this position a young man of the right calibre, by hard work, including a large amount of home study, may equip himself for the highest positions in highway work in Great Britain. Another safeguard of the British engineer, and an incentive to highway engineers in embryo, is the admirable practice which has been adopted in many cases requiring that applicants for a certain class of positions shall hold certain grades of membership in the Society of Municipal and County Engineers and in other cases certain grades of membership in the Institution of Civil Engineers of Great Britain.

France offers an entirely different type of training for men who are going to enter the field of highway engineering. All the important positions in this branch of the public service are occupied by picked men especially educated and trained for the service. After a preliminary general service covering as a final period that comparable with the four years high school training in this country, men of high standing are admitted to the Ecole Polytechnique, the course in which is practically two years in length. Upon graduation from this school, the men of high standing are allowed to select one of the several national schools, provided openings exist, in which they will secure special training for the public service in a given field. Those who enter the Ecole Nationale des Ponts et Chaussees devote three years to a general course in civil engineering under the leadership of engineers of the highest grade in the Department des Ponts et Chaussees de France. During the vacations these men are allotted to service on the construction of roads and bridges in various parts of France. It is evident that the training thus obtained is admirable and that the personnel of the engineering staff of the department of roads and bridges of France is exceptionally high.

In America, while in some cases an attempt has been made to give as special instruction in highway engineering a four years undergraduate course in this subject, this method has not given particular satisfaction for the reason previously noted. Excellent work has been done by many universities in several parts of the country in giving extension courses to groups of men interested in various phases of highway improvement. Very little advanced work, however, has been done through the medium of the American university. The United States Office of Public Roads has evolved a scheme by which men may secure a certain amount of advanced instruction and training in that part of highway engineering dealing with highways outside of built-up districts. This plan is to place the student engineers in the charge of men in the service of the Office in various parts of the country on different kinds of highway work. When it is impossible to work in the field, the men do a certain amount of office work at Washington, receiving instruction by means of lectures on certain phases of highway engineering and also do laboratory work on the testing of both bituminous and non-bituminous road materials.

In 1911, through the generosity of Charles Henry Davis, president of the National Highways Association, there was founded at Columbia University a graduate course in highway engineering. The object in founding this course was to elevate this branch of the engineering profession and to provide an opportunity for men engaged in highway work to obtain advanced instruction and training in the various phases of highway engineering under the most favorable conditions. For many reasons it is fortunate that the first course of this character should be found at a university presided over by a president and trustees who look upon the work of the university from an exceptionally liberal standpoint. While maintaining the high character of all degrees conferred, nevertheless these men believe in opening the courses of instruction to any mature man provided he has the prerequisites for any given course and earnestly seeks information. Likewise it is fortunate that the administrative authorities allow the introduction of an innovation as far as the period of attendance is concerned inasmuch as the graduate course referred to is given in the period from December 1st to April 1st. An engineer, therefore, who desires to take all the graduate courses in highway engineering and allied subjects which fulfil the requirements for the master's degree will necessarily be in attendance for two winter periods, the equivalent of one collegiate year. The selection of this period in which to give the instruction was based upon the prevailing idea among leading highway engineers that it would be feasible for many men to obtain a four months' leave of absence during the dull period of the year. This prediction has been found to be correct.

As this plan is somewhat of an innovation in engineering education, it may be of interest to cite certain facts in connection with the attendance during the winter period of 1911-1912, which was the first period under this plan. Although the graduate courses were not brought to the attention of engineers until November, 1911, there were in attendance fifteen men affiliated with highway work, thirteen of whom registered as candidates for the master's degree. It is of interest to note that this group included men connected with state highway departments, contractors' organizations, municipal departments, engineering-sales departments of manufacturing companies, county highway departments and consulting engineers' offices. The experience of these men ranged from one to twelve years. They came from widely distributed localities, Connecticut, Massachusetts, New York, Pennsylvania, Maryland, North Carolina, Alabama, Panama and British Columbia being represented.

The curriculum of the graduate work in highway engineering comprises advanced courses in the economics and design of roads and pavements, including a thorough discussion of bituminous surfaces and bituminous pavements; highway bridges and culverts; mechanical appliances used in highway gineering; road and street surveying and highway design; highway laws and systems of administration; management engineering; bituminous and non-bituminous road material laboratory courses; seminars in highway engineering literature; chemistry of bituminous materials; engineering geology; optical mineralogy, and inspection trips covering various types of roads and pavements and manufacturing plants producing highway materials.

A large staff of non-resident lecturers in highway engineering, which includes many of the most prominent highway engineers and chemists in the United States, is employed to give instruction on specified subjects forming an integral part of the various courses. It was decided to throw these special lectures open to the engineering public and to hold the same during evening sessions in order that this feature of the work may be of maximum benefit to all that may find the university accessible. An attendance of from fifty to one hundred engineers at many of the lectures during the past winter period showed the interest taken in the many problems of highway engineering presented.

During the 1912-1913 winter period a special arrangement will be introduced which is considered of particular interest to practicing highway and chemical engineers. Many, who cannot secure a four months leave of absence, have expressed the desire to devote from six to seven weeks at Columbia University in securing information relative to the manufacture and testing of all kinds of bituminous materials and their use in the construction and maintenance of bituminous surfaces and bituminous pavements. Arrangements have, therefore, been made so that courses covering the above subjects may be taken either independently or as an integral part of the unified graduate course in highway engineering. During a continuous period of about six weeks, beginning in the latter part of December and ending during the first week of February, three courses will be offered as follows: Two weeks will be devoted to a demonstration lecture course on the mining, manufacture and testing of all kinds of bituminous materials; the next two weeks will be devoted to a course on bituminous surfaces and bituminous pavements; while during the final period of two weeks will be given a laboratory course in which those enrolled will test various types of bituminous materials, make analyses of unknown materials, and write specifications covering the use of bituminous materials under varying conditions. Each course will comprise forty lectures or eighty laboratory hours, depending upon the character of the course.

During the coming year at Columbia it is expected that another innovation will be introduced inasmuch as, in connection with the graduate work in highway engineering, there will be founded several research fellowships by various manufacturing companies. The research workers holding these fellowships will investigate problems of particular interest and value to the manufacturing concerns founding the same. It is expected that many problems of wide interest to those engaged in highway work will be thoroughly investigated through this medium. While admirable work has been done along many lines in the research laboratories of our universities, the speaker earnestly hopes that more attention will be given in the next decade than in the past ten years to the multitude of problems in highway engineering which demand the best efforts of investigators for their ultimate solution.

COAL FOR PANAMA CANAL SHIPS.

Montreal capitalists, including several of the promoters of the Kingston (Jamaica) Street Railway, are behind a project known as the Port Royal Floating Dry and Coaling Docks, Limited. It is the intention of the company to furnish coal to ships using the Panama Canal, which will pass by Port Royal both ways. As a matter of fact, a steamer coming from Liverpool or New York and going to the Far East or Pacific ports makes the first call for coal at Kingston and her last on the return voyage. It is 5,000 miles to Liverpool, 4,000 to Gibraltar, 1,600 miles to New York, and from Kingston to Colon at the mouth of the canal the distance is but 580 miles.

The intention of this company is to build a first class floating dock in England and then tow it to Jamaica, meantime building the coaling station and work shops on land donated by the government. The government will also give thirty years exclusive franchise, besides the valuable site, will admit all the materials and dock duty free and also take a block of the common stock, paying for the same and allowing the interest to be deferred.

The cost of the enterprise is estimated at $2,000,000, and it is understood that a year will be required to build the drydock and local works. There will be a bond and stock issue.

NEW TYPE OF MINE LOCOMOTIVE.

The haulage of cars in and about a mine is a big factor in operative economics considered either from the operating cost or the danger of gas ignition in mines where gaseous conditions are liable to be met with. There have been up to the present, four methods of haulage in general use, hand power, horse-driven, chain and cable drive or electrical. The new type is operated by an internal combustion motor and is entirely self-contained.

Haulage by hand power is allowable only on the smallest of workings; horse driving is expensive in the extreme; chain and cable drive is troublesome and economical only in the richer portions of the mine. Electrical driving is satisfactory under certain conditions, but must be constantly supervised to insure economical operation; then again, there is a great possibility of sparking, a condition that is almost fatal in mines emanating explosive gases. The gasoline locomotive, considering its many good points, would appear to have a great future.

Figure 1 depicts one of these machines in operation in England, where they are manufactured by Messrs. Ironside Son and Dyckerhoff, 40 Mincing Lane, London, E.C. The engine frame is of most substantial dimensions, and carries not only the engine, but also the transmission gear shafts, change speed gears, clutches, etc. A rigid power unit is produced by this means and owing to the absence of universal joints any trouble that might arise following an accident is eliminated. The engine is of a design prepared by the makers with all the cylinders fitted with liners, which may be renewed with a few minutes' labor, and of the horizontal type, well balanced. The speed of this engine is rated for [illegible] r.p.m., and may be accelerated to about 20 per cent. above this rating, should conditions call for such. When throttled down, as during a rest, the engine speed is only [illegible] r.p.m. and the fuel consumption is economized accordingly. The design of the engine almost eliminates vibration.

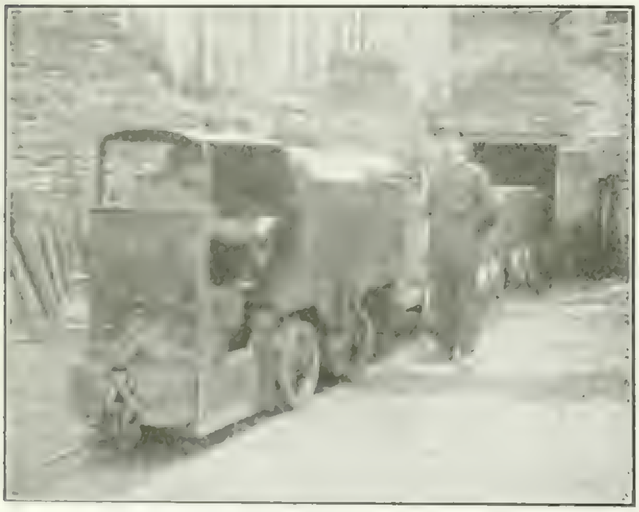

Fig. 1.

In a locomotive of this type, designed with a view of safe working in mines of a gaseous nature, a carburetter that would throw a flame outside the cylinder would be fatal to its use in mines of this type. Consequently the makers have [illegible] attention to this portion of the machine and [illegible] a carburetter that will not give an explosive mixture outside the working cylinder. With this mixing device the [illegible] per British horsepower per hour at full load with petrol as a fuel.

Some of these machines are in operation in the coal collieries in the province of Alberta and for two years have given much satisfaction. We regret that we are unable at the present time to secure photographs of these machines, but as they are much similar to the one illustrated their general outline will be made clear.

◆

SEWAGE TREATMENT VERSUS SEWAGE PURIFICATION.*

By George C. Whipple.

The art of sewage purification has been making progress during recent years. Of this there is no doubt. The nature of the advance, however, has not been that which the popular mind believes it to have been. It has not been in the direction of making sewage more nearly resemble drinking water so much as it has been in adjusting the treatment to particular needs, making the treated sewage fit for discharge into some particular stream or lake, taking into account the subsequent use of this water. The greatest progress has not been in obtaining a higher degree of purity for sewage effluents, but rather in the invention of methods and devices applicable to conditions not previously encountered. To illustrate the general results of that notable series of experiments made a quarter of a century ago by the Massachusetts State Board of Health, at Lawrence, was that the application of sewage to land according to the method known as intermittent sand filtration was the one best suited to the local conditions of that State. Time has proved that this conclusion was correct, and the plants that have been constructed have on the whole given satisfactory results. Intermittent sand filtration gives a relatively high degree of bacterial efficiency. But sandy soils of the proper character do not exist everywhere in the United States; they do not exist in England. Large areas are required and it is not often that these can be found at the proper elevation near large cities. Therefore, this excellent method of sewage purification is much limited in its application. The need of processes to fit other conditions led to the use of improved screens, of chemical precipitation works, of septic tanks, of sprinkling filters, of contact beds, processes excellent in their way, but as ordinarily operated not capable of purifying the sewage to the same extent as the older method of treatment on land.

Yet, and this is the point of my paper, these miscellaneous processes all go popular under the name "Sewage-purification plants." In a certain sense this is correct, for they contribute to the removal of the objectionable ingredients and living organisms in the sewage. The sanitary engineer, knowing the nature of the results, makes a proper mental discount of the term and is not deceived. The layman, however, takes the word "purification" at its face value and is deceived. How many times do we hear city officials proudly boast that the sewage of their city is in no way dangerous because it is purified in a septic tank, when it would seem that the use of one's nose and the application of a little common sense would lead to a different conclusion?

There is no more fatal error in logic than failure to properly define the premises; nothing contributes so much to controversy and misunderstanding as the use of terms of uncertain meaning. The speaker believes that much of the prevailing discussion with respect to the advisability of adopting this or that method of guarding water supplies against infection and of preserving the quality of the water in our waterways has been confused in the minds of many on account of the use of the term "sewage purification" to cover methods and processes that do not make the sewage pure.

---

*A paper read before the general session of the American Public Health Association, Washington, D.C., September, 1912.

It is gratifying to observe that there is an increasing tendency among sanitary engineers to substitute for the term "sewage purification" the words "sewage treatment." Notably, George W. Fuller has adopted this language in his recent admirable treatise on sewage disposal. It is to be hoped that its use will become general. If not, the term "sewage purification" will inevitably become degraded, as people come to learn, as they must, that not all so-called purification plants really purify the sewage. The term "sewage treatment" does not imply complete purification and is, therefore, the more general and the better term.

Using the words in their most obvious meaning, let us ask the question, ought the sewage of our American cities to be purified? Generally speaking, no. To do so would be enormously expensive, and in most cases the results accomplished would not be commensurate with the cost. Ought the sewage of our American cities to be treated in some way before being discharged? Generally speaking, yes. There are relatively few instances where raw sewage can be discharged into streams or lakes without causing objectionable local conditions or dangers of a sanitary character. The nature of the treatment required will vary all the way from a mere straining out of the grosser solids to a combination of processes that results in actual purification.

We hear it said that in England practically all of the sewage is purified. Is this true? Yes, if it is meant that the sewage is submitted to some process that improves its character, but no, if it is meant that these processes completely remove the organic matter and free the sewage of its dangerous bacteria. For example, we like to refer to the interesting sewage works at Manchester and Salford with their great septic tanks and contact beds and sprinkling filters, and we speak of them as purification plants. Do we realize, however, that analyses of the sewage effluents show that during a large part of the time they fall below the standard of purity established by the Mersey and Irwell Joint Committee, a standard that cannot be regarded as too strict if we maintain a reasonable meaning of the word "pure." The biennial report of Hugh Stowell, chief inspector for the Mersey and Irwell district, dated May, 1912, states that out of 126 sewage works, 23 per cent. were non-efficient, this being an improvement over 34 per cent. as shown by his previous report. At Manchester 22 per cent. of the samples were below the established limit for organic matter of "one grain of oxygen absorbed per Imperial gallon in four hours," at Salford 12.8 per cent. of the samples were below standard. This is not intended as a criticism of English methods of treatment, which, on the whole, are well adapted to their particular needs, but merely to illustrate the danger of using loose phraseology.

Or to take another illustration, can the water-supplies of our lakes be protected by purifying the sewage that enters them? Many laymen think so, and ardently advocate the construction of sewage-purification plants and oppose water filtration. Would they say the same if they realized that most so-called sewage-purification plants only partially remove the dangerous substances from the sewage, and that complete removal is impracticable on account of the expense and the almost insuperable difficulty of treating all of the sewage at times of storm? Would not these well-meaning people have a clearer conception of the problem if instead of using the broad misleading word "purification," we used the term "sewage treatment," or still better, some term that described definitely he results accomplished by the different processes.

With laws being framed in various States, to control the pollution of rivers and waterways, it is high time that popular misconceptions should be corrected and that the different phases of this complicated problem should be made clear. In the first place it should be more definitely understood that in the treatment of sewage there are two very different functions to be considered. One is to get rid of the foul, putrescible matter with its accompanying offensive smell; the other is to get rid of living disease-producing organisms. One is very largely a physical and biochemical problem; the other is chiefly bacteriological. One does not directly concern the public health; the other may. In practice, these functions overlap but they may be kept separate.

Is it not the popular conception of the function of sewage-disposal plants that they are intended primarily to protect the public health? Is not this the theory upon which some of the recent legislation is based? It certainly appears so. But is this idea correct? Does the treatment of sewage by the ordinary process materially improve the public health? Are sewage works a success from the hygienic point of view? It is a vital question and one that has not been sufficiently considered from the standpoint of cost and result.

Sanitary history has shown that when polluted water-supplies have been purified by filtration, the typhoid fever death rate of the community has lessened and the public health has otherwise materially improved. And it is a matter of easy reckoning to tell that the financial benefits represented by the saving of human lives and the prevention of sickness have far exceeded the cost of filtration. Taking the cost of efficient water purification at $10 per 1,000,000 gallons, and allowing a per capita water consumption of 100 gallons per day, the process pays for itself if it reduces the typhoid fever death rate by 4 per 100,000.

No such record can be shown for the purification of sewage except perhaps in the case of a few small plants built for the protection of the water-supply of some large city, and even here it is difficult to measure the number of lives that have been saved. The complete diversion of sewage from the drainage area of a public water-supply has repeatedly been of hygienic benefit. So has the introduction of sewer systems in cities and towns where none existed before. But the purification plants that have been constructed for the large cities of the world have not the saving of many human lives to their credit, so far as the best available evidence shows. The reason is obvious. They have not, as a rule, been built for that purpose, popular ideas to the contrary notwithstanding.

Sanitarians abroad have long recognized the fact that river water-supplies cannot be protected against the danger of infection by any of the known methods of purifying sewage discharged into the river above the waterworks intake. Instead they depend upon the filtration of the water-supplies themselves. In Germany the filtration of surface water-supplies is required by law and no difficulty has been found in building water-filtration plants capable of purifying water after it has received what would be regarded in this country as a large amount of sewage. In Germany and in England sewage-disposal works are built primarily to remove organic matter and prevent streams from becoming foul. Therefore, when public health authorities in this country compel large cities to construct sewage-purification plants for the avowed purpose of protecting water-supplies taken from the rivers below them, they are attempting to accomplish the impracticable, and are compelling the expenditure of money without adequate returns. The most that can be expected in this direction is to lessen the burden placed upon the water filters and in some instances this may be desirable.

The pollution of water-supplies is not the only thing involved in this matter. Sometimes it is a question of protecting shellfish supplies, or of bettering the sanitary condition of the water at bathing beaches. These may be fairly classed among the direct sanitary benefits of sewage treatment, but here the treatment to be of benefit must be quite complete and, therefore, expensive, while the number of lives saved is probably small.

It would not be right to balance the cost of sewage purification against the saving of human lives, were it not for the fact that our cities are subject to debt limits and that money is needed for many other purposes that affect the public health; for cleaner streets, for better care of schoolhouses, for parks and playgrounds, and for the special needs of the department of health in securing safer milk and food supplies, and for all sorts of hygienic and sanitary inspections. In view of the steadily increasing tax rates in our large cities it behooves sanitarians to find out for each city in which direction money allotted to the saving of human lives will do the most good. In other words, how can the most lives be saved for a dollar? Whatever the answer may be, it is not likely to be found in the purification of sewage.

That the sewage of most American cities should be subjected to some form of treatment is conceded. The need will increase as our cities increase in size and number. The problem at hand is to determine the most appropriate treatment for each case, bearing in mind the results that can be accomplished, the peculiar local condition, the cost of construction, maintenance, depreciation and operation.

Processes of treatment perform one or more of three functions: clarification of the sewage, oxidation of the organic matter and removal of bacteria. The effect of the methods of treatment now available and in common use are given by Fuller in his treatise already referred to as follows:

Method.	Percentage purification. Suspended matter.	Organic matter.	Bacteria.
Fine screens (10 mesh or finer)	15	10	15
Sedimentation	65	30	65
Septic treatment	65	30	65
Chemical precipitation	85	50	85
Contact filters*	85-90	65-70	[illegible]
Trickling filters*	85-90	65-70	90-95
Intermittent sand filters*	[illegible]	[illegible]	[illegible]

* The figures for the last three forms of treatment are on the assumption that the sewage is given some form of preparatory treatment before it is applied to the filters, and [illegible] settle.

[illegible] primarily to prevent sewage from producing foul conditions [illegible] sonably complete and useful bacterial removal would very [illegible]

[illegible]

ment; they know how well they work when kept in order, and how grievously they fail when not properly operated and enlarged as need requires; they are able to determine what methods or combination of methods are best suited to any case. Yet in common parlance and in official reports they continue to say "sewage purification" when they mean something less. Perhaps a better term than "sewage treatment" can be found, but let us at least be more particular in the use of terms describing the processes discussed, lest the cause of sanitation suffer a reaction from the over-zealous interest of laymen based on false conceptions.

◆

A METHOD OF RECONNAISSANCE SURVEYING.

A method of making reconnaissance surveys herein described has been used for a number of years by a mining engineer who has been employed in examining small mines and prospects in Central America, and was described some time ago in the Engineering and Mining Journal.

There are few mines near the railroads; a journey of two or three days or more may be necessary to reach them, and often the roads over which one must travel on mule back, have never been surveyed. The question as to whether the mine can be profitably worked is often dependent upon the transportation problem, or the possibility of developing power from the nearby water courses. A map of the roads showing in a rough way the topography of the immediately adjacent country is of considerable advantage when such questions have to be considered.

The method that has been used for such reconnaissance surveying is essentially that used by military men. The data for a map are collected as the party travels over the road. The distances are measured by time, the bearings by compass. Starting from a given point the compass man reads the bearing to a certain conspicuous point on the road ahead; the timekeeper notes the time of starting for and arrival at that point, which gives, approximately, the distance. Arriving at that point, another in the road ahead is selected, its bearing from the first observed, and the time taken to reach it recorded. In such manner the bearings and distances of successive points on the road are determined and from the data a map is plotted.

Allowances must be made for the different gaits of the mules, which will vary from 10 to 80 minutes to traverse a mile—horizontally. To make these allowances, some experience is necessary. In starting out, the mule is "standardized" by taking the time required to walk a measured distance on a level road. Such tests are made several times throughout the day in order that allowances can be made for the slower gait of the animal as he becomes fatigued. It is also necessary to allow a different gait in going up and down hills which will in turn vary with the length of the hill and condition and tortuousness of the road. On a level road a mule will average better than 350 ft. per min., four miles per hour, or a 15-min. gait; on steep, rough hills it may make only 66 ft. horizontally per min., or an 80-min. gait. In time the observer becomes experienced in making allowances for gait and greater accuracy is possible.

In keeping notes, the left-hand page of the note book is ruled vertically for: Course, bearing, time of starting, time of arrival, elapsed time, gait factor (indicated by the time required to traverse one mile), and calculated equivalent horizontal distance. On the right-hand page the note-book keeper writes notes and makes sketches to indicate the topography to each side of the road, the rocks out cropping, their strike, dip and character, the rivers and streams crossed and any other features that may be desirable

It is advisable to make frequent observations by aneroid to determine the relative elevations along the road as profiles of at least certain portions of the maps may be wanted. The plotting of the maps is done each night when stopping in some town and the topographical notations are sketched in from the notes while the day's journey is still fresh in mind.

While these maps are far from accurate they are often most useful for making tentative plans that will eventually be based upon accurate surveys made by the usual methods. The plotting of the outcrops often gives an excellent idea of the formation of the region, and, above all else, the engineer becomes familiar with the country far more quickly than would otherwise be the case. Of course, such work delays traveling but the delay is negligible when the value of such records is considered.

As for accuracy, the engineer who has so extensively used this system in Central America has stated that, with a squad of men having had a little experience, two such surveys, over different roads, each about 80 miles long, measured in a roughly circular course, have checked within a mile. Such checking may seem absurd to surveyors but for the purpose of such work an error of one in 80 is accurate enough.

◆

WATER PURIFICATION VIEWED FROM THE HYGIENIC STANDPOINT.*

By Allen Hazen.

The progress in water purification from a hygienic standpoint has been very rapid in the last decade. This progress has been of two kinds. First, there has been a great increase in the number of water supplies that are being purified with satisfactory hygienic results; second, there has been an advance in the standards of efficiency, and in the methods available for reaching them in practical work.

Filtered Water Statistics.—The growth in the purification of water is shown by Table 1.

Table 1.—Population Supplied with Filtered Water at Different Dates.

Year	Population in U. S. Cities of More Than 2,500 Inhabitants.	Population Supplied with Filtered Water. Sand Filters	Mechanical Filers,	Total.	Per Cent. of Urban Population Supplied.
1870	....	None	None	None	0
1880	13,300,000	30,000	....	30,000	0.23
1890	21,400,000	35,000	275,000	310,000	1.45
1900	29,500,000	360,000	1,500,000	1,860,000	6.30
1910	38,350,000	3,883,000	6,922,000	10,806,000	28.20

From Table 1 it appears that the population supplied with purified water increased more than five-fold in each of three successive decades. In 1910 28 per cent. of the whole urban population of the United States was so supplied.

Twenty years ago a considerable proportion of the largest cities of the United States were supplied with water polluted by sewage and notoriously injurious to health. At the present time this practice has mainly ceased. There are still a few of the larger cities that supply water that, in some respects, is not of as good quality as could be desired. But all of the larger cities that supplied notoriously bad water at the date mentioned have improved their supplies in one way or another, and in many or most cases filtered water of excellent quality is supplied at the present time. The smaller cities have followed in the same way but more slowly. While there are some exceptions, a majority of them now have water of at least fair quality.

The statistics above relate to filtered water. They cover only part of the whole field, for in the last years other means of treating polluted waters have come into general use which are important from a hygienic standpoint. No statistics have been compiled to show what additional population is supplied with water so treated, but if it were taken into account it may be conservatively stated that from one-half to two-thirds of the whole urban population of the United States is now supplied with water that has been purified to a greater or less extent.

Advance in Filtration Methods.—The advance in the methods of purifying water from a hygienic standpoint has not been less important than the increase in population supplied with purified water. Some years ago methods of water purification were in common use for treating highly polluted waters which secured the removal of bacteria to the extent of 97 and 99 per cent., and occasionally with well-built and well-operated plants, higher percentages, up to 99.5 and even 99.9 were obtained. These figures relate either to all the bacteria in the raw water or to some portion thereof shown by the methods of examination commonly used. The presumption was that any injurious bacteria that there might be in the raw water would be and actually were removed in as great proportion as were the kinds that could be counted. This was always a matter of some uncertainty and there was reason for thinking, in some cases at least, that the removal of pathogenic bacteria may have been more complete than the removal of bacteria in general. However this may be, it is true that cities supplied with water drawn from highly polluted rivers purified by filtration to the extent above mentioned, were as free from diseases which could be attributed to the public water supply, as cities supplied with upland water of the best quality.

It was obvious that filtration was a relative and not an absolute protection against the impurities of the raw water. Some bacteria undoubtedly passed through the filters, and if pathogenic bacteria were present in the raw water a few of them might pass the filters and reach those who used the water. If a river had a population of 100 per square mile on its catchment area, and if the filter plant removed 99 per cent. of the bacteria, the water after filtration might be compared with water from a river otherwise similar, but with a population of one per square mile.

There was some indication that a falling off in bacterial efficiency had an appreciable effect upon the health of the community. There were notable cases where filters of inferior or inadequate construction, or operated with less than the usual degree of skill, produced, temporarily or permanently, effluents inferior from a bacterial standpoint to those otherwise produced by the best filter plants; and there were cases where diarrhoea, typhoid fever and other indications of water pollution among those who used the water had followed such falling off in efficiency.

Skilful Operation of Filters.—Skilful manipulation of filters must be regarded as equally important with good design in securing at all times an output of well-purified water. The best designed plants may produce poor or bad effluents with careless or unskilful manipulation, and skilful manipulation will do much to improve the average quality of the effluent from old plants not representing modern standards of construction. As the years have gone by, and the number of water purification plants has increased, there has been found a rapidly increasing number of men who have had experience and have acquired skill in operation; and the fact that such men have been available and have been secured to operate purification works has been a most important element in the improvement in the average results that have been secured.

---

* Paper presented before the International Congress on Hygiene and Demography, Washington, D.C.

It is more difficult to keep filters up to a high standard of efficiency during the cold weather of winter and early spring than at other times, and failures of this kind were most frequent at this season of the year. It was perhaps a fair inference that if the use of raw water caused a very great amount of disease among those who used it, and if poorly filtered water during the winter caused a slight though perceptible increase in the same diseases that were caused by the raw water, that the smaller number of bacteria normally passing into the effluent might produce an effect upon the health of those using the water, even though this effect was too small to be measured by such vital statistics as could be obtained.

In the last years the practice of treating filter effluents, as well as raw waters, with hypochlorite of lime has become very common. Applied in very small amounts to clear waters that that do not contain too much organic matter, it produces an extraordinary effect in killing bacteria. This substance had been used for many years as a disinfectant, but usually in much larger quantities. It was something of a discovery to find how efficient it was in extremely small doses in killing bacteria in water free from turbidity and organic matters. This condition certainly could not have been anticipated from earlier practice with it or from the literature on the subject.

Alternative Germicidal Treatments.—Hypochlorite of lime is by no means the first or only substance that has been proposed and used experimentally, and applied in practice in a few small installations for many years. Ozone has been tried repeatedly, but the practical difficulties of carrying out the ozone process effectively, and the great expense of doing it, have operated as obstacles to its general introduction. Hypochlorite of lime seems to have precisely the same bacterial effect as ozone, and it can be applied more easily and is free from some of the uncertainties that have been found adherent to the ozone process. Ozone has some advantages, and if means can be found for overcoming present difficulties its use will be another step in advance.

Sulphate of copper and other metallic salts have also been proposed for killing bacteria as well as algæ in water. It is permissible to use such a substance if it is applied to the raw water prior to filtration so as to secure a disinfecting action, and then have the metallic residue removed in the process of filtration. Some of these processes proved to have merit, especially in connection with filtration, but their use was always limited by the unwillingness of most of those in charge of waterworks to use metallic substances which were more or less poisonous.

The use of hypochlorite of lime has practically superseded all such metallic substances, as it is more efficient and is quickly decomposed in the water into substances that are not poisonous, and within reasonable limits cannot be, by any possibility, injurious.

Other methods of killing the bacteria in filter effluents have been proposed, among which may be mentioned the use of the ultra-violet rays, but no plants for treating water in this way upon a practical scale have been installed in America, and the process is, therefore, one for future consideration rather than of established position.

Hypochlorite of lime has considerable power from a hygienic standpoint, even when applied to the raw water and without filtration. In this case a larger dose must be used and it [illegible] enough must be applied to furnish oxygen for organic and other matters in the water capable of rapid oxidation by its presence, and still leave a sufficient excess to perform its germicidal work. The amount required by the oxidizable matters obviously depends upon the composition of the water, and this frequently fluctuates rapidly from day to day and even from hour to hour. The treatment of raw water has been less efficient and is less satisfactory than the treatment of filtered water, and has not infrequently resulted in occasional overdoses which have been objectionable in the water.

From a hygienic standpoint, the use of hypochlorite of lime is probably the most important event, after the extension of filtration works in the last decade, and where filtration is employed it permits the delivery of water in which the bacteria have been removed uniformly and certainly to the extent of 99.9 per cent. or more.

The use of this process has made it possible to deliver from filter plants of good construction water that is uniformly of excellent hygienic quality. There is no reason to believe that any appreciable danger will result from the use of such water, even when drawn from the most highly polluted sources that are now in use for public water supplies.

With the great extension of filter plants and the development and use of these supplementary processes, the time is rapidly approaching, and has, in fact been reached for a large part of the urban population of the country, when public water supplies cease to be agents for the transmission of disease. On the other hand, many experiences in widely separated cities should teach that constant care is the price of safety, and that every reasonable effort must be made to prevent the occurrence of any condition that would interrupt, even temporarily, the efficiency of the processes that are relied on for safety.

Sewage Purification.—The processes that have been successfully applied for the removal of bacteria from water may be applied, with modifications adapting them to the change in conditions, to removing bacteria from sewage. There has been a renewed effort under the stimulus of these new methods, to secure the disinfection of all sewage to be discharged into rivers and lakes from which public water supplies are taken. This impulse represents a most commendable interest in public water supplies and a desire to protect them from pollution.

It must be recognized, however, that it is more difficult and expensive to remove bacteria from sewage than from drinking water, and the process, even under the most carefully controlled conditions, is at the present time far less certain in its operation when applied to sewage.

The question of the combined or separate system in sewers, the treatment of storm overflows and the treatment of street washings discharged by drains which do not carry sewage, all have to be considered in connection with this general question.

Up to the present time improvement in public water supplies has come almost entirely through methods of improving the water used. Improvement of water supplies by purifying the sewage that flows into the water from which they are taken has played hardly an appreciable part in the improvement of water supplies in America.

Looking at the matter broadly, these conditions must be expected to continue for the present, and further improvement in water supplies is to be expected from improvements in methods of purifying the water, and from increased care and faithfulness in carrying them out rather than from the more extended use of sewage purification.

◆

A contract has been signed between the town of Greenfield Park, Que., and the Montreal and Southern Counties Railway Company, in which the town gave the railway company a twenty-five years' franchise, and the latter agreed to give the town a satisfactory electric train service, to be inaugurated on or before July 1st, [illegible]. Suggestions have been made that the service will be in operation by the end of this year.

THE MUNICIPAL ENGINEER

The city of London has lost the services of their city engineer, Mr. George Wright. Mr. Wright has handed in his resignation as the result of certain statements and criticisms made by the mayor and members of the city council.

The number of engineers who have held the city engineership of London is rapidly increasing. The most recent to have accepted the position only to leave it at an early opportunity are Mr. Graydon and Mr. A. H. VanCleve. Mr. Wills McLaughlin was city electrical engineer also for a period of a few months. These men are known to the profession throughout Canada as capable men and good engineers. What, then, is the trouble in London? Were these men unable to meet the requirements of the position?

The answer is the same one that may be given to the recent trouble in Calgary, when Mr. J. T. Childs, the city engineer, resigned, and to the investigation now pending in Ottawa into the city engineer's department: the absolute lack on the part of city councils of the elementary principles of fairness in dealing with municipal officials, and their utter ignorance of the conditions of engineering work.

Mr. Childs was forced to retire from the city engineership of Calgary after many years of service as the result of a most absurd accusation. Mr. Wright now resigns from the city engineership of London on the trivial charge of poor construction of certain sidewalks. A knowledge of the facts which led up to both of these resignations must convince an unprejudiced observer that the day of usefulness of city councils is rapidly passing.

Suggestions have been made recently as a result of the constantly recurring troubles between city councils and city engineers, that the Canadian Society of Civil Engineers should take up an active policy with the aim of securing more just treatment for the members of the profession following this line of work. We doubt very much if any good purpose would be served by interference on the part of the Canadian Society in the endeavor to ameliorate conditions. The constant criticism and the nagging and fault-finding of municipal councils is due primarily to their comparatively low order of education, and, therefore, to their consequent inability to understand the engineer's work. The members of municipal governing bodies are chosen, as a general rule, on account of their political ability and wire-pulling capacity; and these qualifications are not usually developed in marked degree in the modern, well-educated man. The doctrine of the survival of the fittest is well exemplified in the usual city council of to-day; and the fittest there, is the vote-getter, the man who may be called a "good mixer."

The present method of election of city council by popular vote is not conducive to the obtaining of a high standard of municipal governing body, and it is the city engineer who has been the first to feel the evils of the system.

As we have said, we do not believe that the Canadian Society of Civil Engineers can do anything to help conditions. The trouble lies in the city councils, and the remedy is there also. Until the commission form of municipal government is brought into force, trouble will continue to develop between the city engineer and the municipal governing body.

Engineers with municipal training, and inclination for municipal work, will be cautious in accepting a position as city engineer of London after the past history of the position.

CANADA AND THE NICKEL SUPPLY

While it seems unlikely that the Dominion government will prohibit the export of nickel from Canada except to Great Britain—a suggestion made recently—the hint is a key to an interesting story. Prior to the time of war crisis, such a prohibition might prove an effective weapon. The official reports of mineral production in Ontario show that in 1910, the latest year for which such figures are available, there were raised from the nickel-copper mines of Sudbury 652,392 tons of ore, of which 628,947 tons were smelted in the blast furnaces and put through the converters. The product was 35,033 tons of Bessemerized matte, 23.6 tons of ore being thus required on an average for one ton of matte. In this quantity of matte there were contained 18,636 tons of nickel, last year's output, 13,141 tons, being exceeded by 5,495 tons, or over 41 per cent. The production of 1910 was much the largest since the nickel mines of Sudbury were opened, a quarter of a century ago, and stamps this field as being the most important source of nickel in the world. The value of the nickel contents of the matte, on the basis of what it is worth —or estimated by the producers to be worth—at the point of production is $4,005,961.

To the output of the Sudbury mines must be added, for the sake of completeness, the nickel contents of the silver ores raised at Cobalt, estimated to amount to 504 tons, bringing the total yield of nickel in 1910 up to 19,140 tons.

Monel metal, an alloy of nickel and copper, which has been placed on the market by the Canadian Copper Company, and which is produced by that company without separating the metals or either of them from the matte, has aroused great interest. It is asserted that the proportions in which the nickel and copper occur in the Canadian Copper Company's ores are almost precisely those required for the alloy, which are about 67 per cent. nickel and 27 per cent. copper, and that by careful attention to the furnace charge a Bessemer matte can be produced within one per cent. of that required in making Monel metal. Considerable quantities of this alloy are now coming into use. It is claimed to possess great strength and to be practically non-corrodible. It has been employed as castings in the manufacture of propellers for vessels of the United States navy and private yachts, in pump linings, steam turbine nozzels and valve fittings for superheated steam, in dairy machinery, refrigerating plants, and pickling apparatus in steel mills; in rod form, for pump rods, bolt and nut stock, steam turbine parts, stock for drop forgings, electrical apparatus, motor boat shafting, pickle pins and valve stems; as sheets, for roofing railway terminals and other large buildings, for mine screens and chutes, smelter roofs, skylights and window frames, boat sheathing, cooking utensils and chemical apparatus, also for steam turbine blades; in the form of wire for wire cloth, motor cycle spokes, rope for mine hoists and cableways, nails, screws, rivets, etc.; and many other applications where high tensile strength, combined with non-corrosive features are essential.

The use of nickel for coinage purposes is spreading. In 1910 the Government of Turkey was authorized to put out an issue of coins made of nickel or aluminum. The latter metal, upon being tested, not having given satisfactory results, nickel was decided upon, and it has been resolved to issue 120 millions of 5-para pieces, 120 millions of 10-paras, 70 millions of 20-paras, and 20 millions of 40-paras, in all 330 million pieces. The money is all to be coined in four years and issued in twenty.

The only other important source of nickel is the island of New Caledonia, whose output, however, in proportion to the whole, is now much less than that of Sudbury. Societe le Nickel, whose production is of New Caledonian ores, operates refineries in France, England and Germany. From 1900 to 1909 the French production fell from 1,700 to 1,200 tons, while that in England rose from 1,500 to 2,800 tons, and in Germany from 1,400 to 3,100 tons. Thus in 1909 the total output of nickel from New Caledonia was 7,100 tons. In the same year the yield from the Sudbury mines was 13,141 tons.

◆

EDITORIAL COMMENT.

A statement from Ottawa this week does not bode well for the success of navigation in Hudson Bay. The naval service department, it is said, has had to abandon the scheme to send coal to points in the Hudson Straits for steamers owing to the refusal of the insurance company to insure the vessel which was to be sent. The vessel chartered was the Eric, owned by the Job Brothers, St. John's, Nfld. It is a sealing vessel, strongly built and equipped for ice work, yet the insurance company would not take the risk, chiefly because in case of accident very few vessels are in the vicinity to render assistance. The Pacific Coast outlet for Western Canada has no such drawback.

◆

GENERAL NOTES.

The precipitation of the month of September was somewhat less than average the larger part of British Columbia, and over Eastern Quebec and the Maritime Provinces, while over the remainder of the Dominion, exclusive of the Districts of Nipissing and Muskoka in Ontario; and of Southern Saskatchewan and perhaps some areas in Northern Alberta, it was in excess. The excess was particularly marked in Southern Manitoba, and in the Lower Ottawa Valley, where almost double the average quantity was recorded. Light snow fell in some few localities in the Western Provinces, and severe thunderstorms occurred in all the Provinces.

The table shows for fifteen stations, included in the report of the Meteorological Office, Toronto, the total precipitation of these stations for September, 1912:

	Depth in inches.	Departure from the average of twenty years.
Calgary, Alta	2.8	1.56
Edmonton, Alta	1.1	−0.40
Swift Current, Sask.	1.1	−0.23
Winnipeg, Man	5.5	+3.58
Port Stanley, Ont	[illegible]	+0.11
Toronto, Ont.	3.28	+0.43
Parry Sound, Ont	3.5	0.06
Ottawa, Ont	4.3	+1.68
Kingston, Ont.	4.8	+2.20
Montreal, Que	6.4	+3.01
Quebec, Que	3.3	−0.47
Chatham, N.B	2.3	−0.83
Halifax, N.S.	3.4	—0.61
Victoria, B.C.	0.7	−1.40
Kamloops, B.C	0.8	−0.19

SPILLWAY CAISSON DAM.

Enough of the material for the floating caisson for Gatun Dam Spillway has arrived on the Isthmus from the United States to allow the contractors for its fabrication and erection, the McClintic-Marshall Construction Company, to begin the erection within a short time, is the statement in the current issue of The Canal Record. Inasmuch as the caisson will not be required until after the coming dry season, it will be erected at an elevation between 55 and 60 feet above sea level, on the lake side of the east wing of the dam, there being ample time to complete the caisson before the rise of the lake surface above elevation plus 50 feet; while shortly after the spillway gates have been closed, further to raise the lake, the caisson can be floated off and held ready for service.

The caisson is to be used as a temporary dam for the passages between piers of the spillway dam, when it is desired to repair the Stoney gates by which the passages will ordinarily be controlled to regulate the surface of the lake. When a gate is to be repaired, the caisson will be towed from its moorings at the side of the spillway, and swung into place between the piers supporting that gate. Water will be let into the caisson through intakes below the water line until it sinks into position on top of the ogee and against the vertical seats provided on either side. The downstream side of the caisson will then be six feet six and three-fourths inches from the face of the gate After the placing of the caisson, the gate will be raised slightly to unwater the space between it and the caisson. This will cause a heavy pressure from the lake on the caisson, forcing it more tightly in place, and will afford room for workmen to operate on the upstream side of the gate.

When it is desired to remove the caisson the gate will be lowered and the space between it and the caisson will be filled with water, to the level of the lake, through a pipe passing through the caisson and controlled by a valve. The pressure of backwater having been relieved, the caisson will be pumped out and floated away.

In outward appearance the caisson will be a simple rectangular box. The framework, consisting of vertical and horizontal girders, supporting a system of intercostals to form the skeleton, will be covered on both sides with steel sheathing plates, so as to form a watertight box into which will be put a sufficient amount of concrete ballast to cause it to float upright and at the proper depth in the water. Timber keels and side sills are provided to make tight joints with the ogee between piers and the vertical seats against which the caisson will rest when in use.

The horizontal girders, three in number, and the top truss will be 49 feet 6 inches long by 4 feet 3 inches wide, with web plates ½-inch thick. They will be bolted at the ends to the two vertical girders, 22 feet 6 inches long, 5 feet 9½ inches wide, and ½-inch thick in the web; and each of the three long spaces thus formed will be crossed at right angles by nine vertical intercostal plates ⅜-inch thick. This sheathing will vary in thickness according to the pressure on it, from ⅜ to 7-16 of an inch All of this material will be of specially tested structural steel.

For ballast, concrete will be laid approximately two feet six inches deep over the entire bottom girder, with a slight grade toward a sump near the centre. A number of movable concrete blocks, eight inches square by six inches deep, will be placed on top of this as a means of adjusting the ballast.

The pipes for letting water into the caisson are located above the second girder, holes in which will allow the water to drain to the bottom. These pipes are two in number, four inches in diameter, and controlled by long-stemmed valves operated from the girder above. Swash bulkheads will minimize the rolling of the water within the caisson, assuring steadiness. The flange pipe, through which water will be let into the space between caisson and gate at the conclusion of repairs to the latter, is at the same level as the filling pipes and between them. It will be ten inches in diameter, of cast-iron, and controlled by an extension valve similar to those for the filling pipes.

The pump for unwatering the caisson, to float it, is to be of the horizontal force type, hand-operated by two handles. It will have a 6-inch stroke, and will draw water from the sump in the ballast through a 3-inch suction pipe and force it out through a 2½-inch discharge pipe, emptying through the side of the caisson about a foot below the top. When the caisson is sunk in place on its seat, its top will be two feet eight inches above the surface of the lake at the maximum elevation of 87 feet above sea level.

Trap doors and ladders will be provided to allow workmen access to the interior of the caisson. The top truss will be decked over with yellow pine lumber; and the keels and end sills will be of white oak. The caisson complete will contain approximately 53 tons of structural steel. The caisson for Miraflores spillway will be of identical construction.

◆

DETERMINATION OF STRESS.

Professor E. G. Coker read a paper on the "Experimental Determination of the Stresses in Springs and other Bodies by Optical and Electrical Methods" before the Engineering section of the British Association.

He pointed out that usually the chief difficulties in determining the state of stress in a body arose from the great variations of stress intensity which occurred owing to its complicated shape and the loading; and, further, in the case of springs where plates were built up into a matrix, the rubbing friction between the surfaces was usually sufficient to render the assumptions of perfect elasticity of the whole body somewhat untrustworthy for purposes of calculation, although each plate might be regarded as fulfilling the elastic conditions perfectly.

Methods of experiment were described by optical and electrical methods of general application to stress problems. In the first method, models of springs were constructed of transparent materials for which it was shown that the stress distribution was very similar to that in steel. These models permitted of determinations of the difference of principal stresses at any point, and an important result was that the optical effect of a pure shear was proportional to twice the numerical value of one of the principal stresses. Examples of plate springs and flat-coiled springs were considered in detail, and the general distribution of stress was illustrated by diagrams and natural-color photographs of springs viewed in polarized light. The second method depended on the fact that steel and other metals when subjected to stress within the elastic limit experienced a change of temperature—a diminution for tension stress and an increase for compression stress—proportioned to the stress. The effect at any point, therefore, was due to the sum of the principal stresses, and in coses of pure shear the effect was zero—a noteworthy difference from the first method. The paper described some attempts to utilize the difference in the electrical condition of stressed and unstressed metals for determining the stresses in materials.

The new United States Navy collier, "Jupiter," is fitted with electrically driven engines. She has a displacement of 19,300 tons, and is designed to carry 12,000 tons of coal as cargo, and for a maximum speed of fourteen knots. The machinery is reported to show a considerable saving of weight as compared with the reciprocating engine.

THE ANGUS SHOPS OF THE CANADIAN PACIFIC RAILWAY.

The Canadian Pacific Railway maintain at this point, which is near the city of Montreal, the largest and best equipped shops in America for the maintenance and manufacture of railway rolling stock. It would be impossible to secure even a slight idea of their immensity from a photograph but in order to show something of their extent the drawing, Fig. 1, has been prepared. The various buildings may be located and identified by reference to the following table, the numbers of which correspond with those on the drawing.

Further information regarding these shops may be secured by reference to our issue of January 24th, 1912, which was one of the daily numbers issued in Montreal during that month.

THE SUPPLY OF NICKEL.

The situation in the Sudbury district, Ontario, with respect to the competition in the supply of nickel for use in the nickel-steel industry, has changed considerably in the past few months, states the Iron and Coal Trades Review. The International Nickel Company, acting through its subsidiary company, the Canadian Copper Company, has, up to the present, been the main producer from the Sudbury district, controlling in all about 70 per cent. of all the Sudbury output, which output represents about 75 per cent. of the total nickel product of the world. The Mond Nickel Company has produced about one-fourth of the Sudbury output, while the International Nickel Company has also large interests in the new Caledonia fields. At one time, the International Nickel Company was controlled by Mr. Charles M. Schwab, but about 1907 the control was taken up by Messrs. Converse, Monel, Delamar and Thompson. Prior to Mr. Schwab's advent into nickel, Mr. Joseph Wharton, of Philadelphia, Judge Burke and Mr. Richie, of Cleveland, had been dominating factors in the nickel situation. Recently the International Nickel Company extended its capital from $10,000,000 to $50,000,000. This will result presumably in a close alliance between the International Nickel Company and the United States Steel Corporation, in effect at least. While the International has been strengthening its position and increasing its activities, a Canadian company, known as the Dominion Nickel and Copper Company, has made some important purchases of new properties. This company is controlled by [illegible] represented by Mr. [illegible] of [illegible] and Mr. M. J. O'Brien, of Montreal. [illegible] in the Sudbury district. It had been reported that the American Smelting and Refining Company had made an investigation of the district and [illegible] options. Some smaller interests have sought to enter the nickel field, principally representing [illegible] connections, that are now using nickel extensively, presumably for naval and military [illegible]

ASPECTS OF STEAM RAILWAY ELECTRIFICATION.

The advent of electricity into the steam railway field has not been very rapid. However, several railways in the United States have adopted electricity as motive power for suburban or interurban service. Professor C. L. de Muralt, in an article published in the Railway Age Gazette, outlines the present status of steam railway electrification. We present the article in full.

Let us see what has thus far been accomplished in trunk line electrification and what is likely to be done in the future.

We have to-day at least seven prominent steam railways that are using electricity as motive power on one or more of their main line divisions.

(1) The Baltimore & Ohio, at its Baltimore terminal.

(2) The New York Central, at its New York City terminal.

(3) The New York, New Haven & Hartford, at its New York City terminal and at the Hoosac tunnel.

(4) The Pennsylvania, at its New York City terminal, and on parts of the West Jersey & Seashore.

(5) The Great Northern, at the Cascade tunnel.

(6) The Grand Trunk, at the Sarnia tunnel under the Detroit River.

(7) The Michigan Central, at the tunnel under the Detroit River.

With the exception of the West Jersey & Seashore, every one of these electrifications was caused through the presence of a tunnel, which made further operation by steam locomotives either difficult or impossible. Whatever economies in operation were secured through the use of electricity may be said to have been incidental in all these cases.

Does this mean that electricity will be restricted to places where tunnels form a hindrance to steam operation? A careful examination of the matter shows nothing to confirm such a view. Smokelessness is only one of the advantages of electric traction. As matters stand to-day it will hardly be considered its most valuable one. There is one that is likely to prove of much greater importance. It is the fact that the electric engine possesses inherent qualities, which make it a much more powerful traction machine than its steam rival. To show just how this characteristic has already been utilized and to what extent it is likely to influence further developments is the purpose of this article.

The work which any given engine can do is dependent on three things, tractive power, boiler power and engine power, and it is limited in three ways.

(1) The tractive power is limited by the weight of the engine, or rather by that portion of the weight which is placed on the driving wheels. Any increase in weight on drivers means a proportional increase of tractive power, and for any given weight on drivers there is a certain maximum power which the engine can exert, and beyond which it must necessarily slip its wheels.

(2) The size of the boiler determines the quantity of steam which can be produced in a given time, and thus limits the steam producing or boiler power. If the engine uses more steam than the boiler can produce, the boiler pressure will fall and the engine will then be unable to turn the wheels.

(3) The capacity of the cylinders in a steam engine, or of the motors in an electric engine, limits the mechanical or engine power. If these parts are not sufficiently powerful, then the engine will be stalled, even while utilizing to the utmost a full pressure of steam and while yet unable to slip the drivers.

It may be said at once that the last is in general an unpardonable fault for any engine to have, because it is an absolutely needless sacrifice of a good part of its working capacity. With proper care in the design of its steam cylinders, or proper choice of the electric motors, it is always feasible to make the engine power in excess of either the tractive power of the boiler power, or both. The limit to the work which can be done by a well designed engine need therefore never lie in its motor part. It is always due either to insufficient tractive power or insufficient boiler power.

On these two points the electric engine shows its superiority over the steam engine. The electric engine has the boiler in the power house, and its size can thus be determined without reference to the limitations which are imposed on the boiler of the steam engine by the physical characteristics of the track and of the fireman. In other words, by proper design the limitations of the boiler power can be entirely removed in any system of electric traction.

Similarly, we find that the limitations of tractive power may be practically eliminated wherever electricity is used, because the electric motor lends itself to subdivision of power with such ease, that it is quite possible, in case of necessity, to turn any desired number of axles into driving axles, and thus to utilize any desired part of the weight, up to the full weight of the train, for tractive purposes. The tractive power which is thus made available is away beyond anything that is likely to be demanded in railway work.

Now, let us see how these two characteristics of the electric engine may be utilized.

Our contention is, that electricity is peculiarly suitable for the relief of all congested spots on the present steam roads. We have two main cases of congestion, namely, terminals and ruling grades.

We started by saying that the electrification of the New York terminals of the New York Central, the Pennsylvania and the New Haven railways was largely caused by the necessity of avoiding smoke in the tunnels that form a part of these terminals. But it would be wrong to assume that the matter stopped there. The men who had charge of these installations fully realized the other advantages which were thus incidentally placed at their disposal. In such cases it is especially the removal of the limitations on tractive power which is of considerable value.

It is a fact well known to all superintendents of motive power that it is difficult to make a fast schedule in dense suburban passenger traffic, even with the most powerful steam engines especially designed for such service. The reason is that with steam locomotives there is a distinct limit to the amount of weight that can be placed on the drivers. From this results a limit to the tractive power, and consequently a limit to the ease with which heavy trains can be started and brought up to the speed. Even the highest obtainable rate of acceleration is too low to give a really satisfactory schedule speed when stops average about one mile apart. Furthermore, the number of cars that can be hauled in such a train is distinctly limited.

Electricity changes the situation completely. Any number of axles can be equipped with electric motors, and thus the tractive power can be raised to any desired amount. In actual practice an electric train can readily be accelerated two or three times as fast as even a light steam train, and there is practically no limit to the number of cars that can be placed in an electric train. The congestion is thus relieved in three ways, first, by the possibility of using larger trains; second, by the chance of higher schedule speeds, and third, by the greater ease with which the trains can be moved out of each other's way, that is to say, by the possibility of decreasing the interval between trains. In actual practice all three methods are usually combined with resultant satisfaction to passengers as well as the railway.

In the case of congestion due to severe grades, on otherwise level or low-grade lines, the conditions are reversed. In such instances the maximum tractive power is usually quite sufficient; in other words, the obtainable acceleration is satisfactory, but it is the boiler power which causes trouble. In order to lift the train up the grade, the engine must consume more and more steam until a point is reached when the boiler is unable to produce any longer what the engine requires. Then, either must the train weight be reduced, or its speed, or both. This is what actually happens on the ruling grades of most of the lines crossing the Alleghenies, the Rockies, and other mountain ranges. Helper engines mitigate the nuisance to a certain extent, but there is a limit to the number of helpers that can consistently be used on one train, and when this limit is reached, the trains are made lighter at the bottom of the grade, or their speed is cut down, or both.

Here, again, we find that the use of electricity completely changes the situation. There is no limit to the power which the boilers in the far-off power house can produce, and this power can very readily be carried to the engines in the form of electric current by means of the third rail or overhead contact line. Thus it is possible to concentrate sufficient power in an electric locomotive to take any train up the grade in the same composition in which it arrives at the bottom of the grade, and with the proper type of motor this can be done at the same speed at which it is run on the level. The congestion produced by the grade is thus effectively removed. In fact, one might almost say that for electric operation the vertical profile of a road loses all of its terrors, and trains can be taken over the most broken profile almost as well as over the level road.

We see, therefore, that the excess power of the electric engine can be made useful in at least two ways. The electrification of terminals is likely to make further steady, but comparatively slow progress. As a matter of fact, there are not very many places where terminal congestion has reached such a state as to make the use of electricity necessary, or even very important. The electrification of heavy grades, however, is destined to find more and more favor, especially because the business of the country is on the increase and any congestion now existing is therefore likely to be aggravated in the near future. At the Cascade tunnel of the Great Northern a heavy grade has been electrified in addition to the tunnel, and the results there obtained are certainly quite encouraging.

As regards the kind of system to be used, too much importance has been attached to this subject in the past. There are to-day at least three well established electric systems, namely, the continuous current or direct current system, the single-phase alternating current system, and the three-phase system. Any of these can no doubt be used to electrify almost any [illegible]

Just as there are many different types of steam engines, and at least three types of approved valve gears, so is there room for many different kinds of electrical motors.

The fact which is important is that in the electric locomotive of proper design we have an engine of much greater working capacity than can ever be obtained in a steam engine. This greater capacity can be used, either to give greater acceleration in terminal work or to move heavier trains at higher speeds over ruling grades. the latter employment in particular is likely to prove of great value in the case of roads where a severe grade produces a congestion, and thus a decrease in the traffic capacity of the whole line.

In a future article we will investigate whether grade reduction, or the use of Mallet engines, or both together, can afford as great a return on the capital invested, or offer the same operating advantages as electrification.

◆

SHERBROOKE RAILWAY REPORT

"During the year," states President C. J. McCuaig, of the Sherbrooke Railway and Power Company, in the annual report, "some important steps have been taken in connection with the company's affairs, and the scope of its operations has been extended by the acquisition of several companies, with established businesses, in the district between Sherbrooke and the international boundary line. Legislation was obtained at the last session of the Quebec legislature ratifying these contracts and still further extending the company's powers. The companies acquired consist of the Eastern Townships Electric, the Stanstead Electric and the controlling interest in the Lennoxville Light and Power Companies.

"To provide funds for the purchase and extension of these properties, building transmission lines, and the extension of the company's main system, the company issued $348,500 additional bonds and $348,500 stock, which they have sold.

"Negotiations are pending for the sale of another large block of the company's power and it is reasonable to expect that a market will be found for the greater portion of the remainder of the power developed before the expiration of the year.

The following is the statement of profit and loss for the year ending June 30 last:—

Railway and power operations:—			
Gross earnings		$64,500.71	
Operating expenses		43,616.98	
Net earnings			$20,883.73
Real estate:—			
Rentals			$ 990.65
Stanstead and Eastern Township's Electric Company's			
Gross earnings		$23,148.58	
Operating expenses		12,975.63	
			$10,172.95
Lennoxville Light and Power dividend			$ 800.50
Net profit for 1912			$32,847.83
Balance at credit, 1911			3,694.46
			$36,542.29
Less:—			
Bond interest	$41,077.66		
Less interest charged to portion of system under construction	8,000.00		
		$33,077.66	
Accounts written off:—			
Railway department	$ 532.86		
Power department	590.22		
		$ 1,123.08	$34,200.74
Balance carried forward to the credit of profit and loss			$ 2,341.55

ELECTROLYTIC DISPOSITION OF SEWAGE.

The treatment of sewage is taking on added importance as time goes on and the necessity for preventing further pollution of lakes and streams increases. Mr. F. C. Caldwell, in the June bulletin of the Ohio State University, takes up the present status of electrolytic methods of purification. In the following we present his discussion.

The electrolytic purification of sewage is not new, patents covering the system have been taken out in England nearly a quarter of a century ago. It has, however, been recently revived with such a degree of success, as makes it fitting that it should be considered by this association, to the members of which its general adoption might be of considerable importance.

The material to be handled is made up of domestic sewage, sometimes accompanied by factory wastes and more or less diluted with storm water. Domestic sewage is made up of organic matter that is animal and vegetable, partly dissolved and partly suspended in water. There are also present vast numbers of bacteria often thirty to fifty million in a cubic inch. Factory waste when present may be of any one or more of many kind and affects the problem differently according to its nature. It is therefore not considered in this paper.

The degree of dilution of the sewage to be handled will vary greatly, depending both upon the habits of the population and upon the amount of storm water. In general, it is much more dilute in this country than in Europe. The large proportion of water greatly increases the difficulties of handling the sewage.

The presence and action of the bacteria constitutes one of the most important factors in the problem. They may in general, be divided into two classes, the purifying, also called anaerobic, because they flourish without oxygen, and the oxidizing or aerobic, which as indicated by their name, require oxygen for their best development.

The purifying bacteria operate in the sewers and in any closed reservoir or septic tank in which the sewage may be held. They are helpful in that they digest or liquify any solid portions, but to their action are due the offensive odors which characterize stale sewage. It is therefore essential that their action should be for the most part stopped before the sewage is turned into rivers or other water.

The oxidizing bacteria on the other hand, oxidize or "burn up" the organic material reducing it to simple, stable and inoffensive matter in which condition it ceases to be a nuisance, especially when further diluted with river water. As indicated above, their action is promoted by the presence of air and goes on without offensive results even after the sewage has been turned into the river. They can, however, act only effectively upon finely divided matter, and it is therefore usually desirable for their action to be preceded by that of the putrifying bacteria.

There are also to be considered the disease producing bacteria, originating in the human body. Of these the most notable is the typhoid bacillus. These, if simply run into the river water will remain alive for considerable periods, but they do not flourish under such abnormal environment and are not difficult to eliminate. In many plants it is not considered necessary to sterilize against such bacteria except at times of epidemics.

Any system of purification, to be a success, must leave the sewage inoffensive in appearance and in odor. Practical elimination of the disease producing bacteria is also desirable. Generally, also, the sewage must be to such an extent oxidized that there will be no danger, under the conditions of its disposal of purification again setting in. It is not sufficient to eliminate the putrifying bacteria as there are enough to be found in the river or other water to start the process and once started the rate of increase is enormous. It has been estimated that under unnaturally favorable conditions one bacterium would in twenty-four hours give rise to sixteen and one-half millions.

Granted that a new system accomplished these functions satisfactorily, it would still remain to be demonstrated that it did so more economically than other methods already available.

Before inquiring into the effectiveness of the electrolytic method it will be well to describe its operation. The following relates to the latest plant, a description of which has been published, namely, that at Oklahoma City, (population in 1910, about 64,000). This plant was put in operation on March 29, 1911, and was designed to handle 750,000 gallons of sewage per day. One or more of three flumes 18 x 20 in cross sections and 30 feet long received the sewage. This comes from the city through a conduit about a mile in length and the flow through this is an important factor as it assists in the mechanical disintegration of the sewage as well as serving as a septic reservoir for the action of putrifying bacteria. Each flume is designed to care for 250,000 gallons of sewage per day. The electrolysis is effected by ten groups of iron plates, each group consists of 27 plates, 3-16 x 10-24 spaced ½ inch between surfaces. These may be likened to the elements of a storage battery of such size as to nearly fill up the flume, and with their faces parallel to its sides. Alternate plates are positive and negative, and are connected to bus bars run along the edges so that all the groups of plates are in parallel. The bus bars are supplied by a 3-kw. motor generator set with current at from 1½ to 3 volts. Each flume takes normally 270 amperes. A reversing switch is included in the circuit, and changing the direction of the current once or twice a day equalizes the wear on the plates and removes the deposit which forms upon them.

To prevent excessive electrolysis at the upper edge a copper binding is used. The plates are gradually dissolved and take part in the chemical action upon the sewage.

The effluent is discharged into a so-called "dry gulch," and the sediment deposited in the flumes is periodically flushed out into the same gulch.

The Oklahoma plant was established on the strength of the results obtained from one installed at Santa Monica, California, population 11,000 to 18,000, depending upon the time of year, in June, 1908, and was modelled closely after it. The Santa Monica plant, however, discharges the effluent into the ocean 1,600 feet from shore. In passing, it is interesting to note the surprising lack of knowledge of things electrical evinced in the installation of this system. For example, magnets were placed over the plate electrodes for the purpose of intensifying the action of the current upon the sewage, but were easily removed.

We come to the perplexing question—Does the electrolytic method satisfactorily "purify" the sewage? Two causes of purification are claimed, namely, the production chemicals which are strongly oxidizing or chlorinating in their nature and the production of oxygen itself in the so-called nascent state, in which it is very active chemically. That such chemicals are formed and that they do operate to destroy the bacterial life they reach and to some extent to oxidize the organic matter itself is undisputed. The part played by the nascent gases is more doubtful as it seems to have been well established by Geo. W. Fuller in an extended investigation at Louisville (see his "Sewage Disposal," page 557) that such oxygen is almost entirely used up in attacking the iron plates. Further, the gas ceases to be nascent almost immediately after its formation on the surface of the plates and hence any direct action due to it would only take place in a very thin layer next to the plates, so that a small portion of the liquid would be affected.

An illustration of the efficacy of the electric current in the destruction of bacteria is found in some tests made some time ago by Dr. C. B. Morrey, of the Ohio State University, and the author, on the electrolytic sterilization of milk. In a sample of market milk containing 19,480,000 bacteria per cubic centimeter, an application of 2.5 amp. at 2,000 volts alternating current for 15 seconds reduced this number 99.97 per cent. Another similar test showed a reduction 98.7 per cent. and a third, in which the milk was inoculated with diphtheria bacteria in very large numbers, showed their practically complete destruction. Chemical examination of the milk showed no changes which would account for the sterilization nor could this be accounted for by the heating which took place.

The evidence seems quite conclusive that where the sewage has received suitable disintegrating and digesting or purifying action previous to the electrolytic treatment the effluent, immediately after each treatment, is practically odorless and free from bacteria. The question which does not seem to be satisfactorily answered is "Has organic matter been so far oxidized that it can be relied upon not to again putrify and thus develop a nuisance in the stream through which it flows?"

The experience at Santa Monica where the effluent, in comparatively small amount, is deposited in the ocean over a quarter of a mile from shore cannot be taken as indicative of the results which would follow where a comparatively small stream were made use of. The case of Oklahoma City, where the effluent is run into a dry gulch, is perhaps more instructive, though even here the conditions are so different from those usually met with in this part of the country that they should not be given too much weight. There being presumably no other water in the gulch through most of the year, there might be no such supply of putrifying bacteria as would be found in most streams. Again, if the soil is sandy the effluent may sink in before it has had time to develop further putrefaction. The effluent as it comes from the plant may be somewhat antiseptic, which would discourage the growth of putrifying bacteria for a considerable period. This condition, however, might soon cease if the [illegible] sewage were diluted in a relative small stream.

On the other hand, the advocates of the system claim that the organic material is actually oxidized or rendered [illegible] and most of the evidence given in the published accounts is to the effect that whatever the sewage [illegible] it [illegible] does not putrify after being subject to the electrolytic treatment, and after all "the proof of the pudding is in the eating," though we might not go so far as to say that the proof of the sewage is in the drinking.

[illegible] the available data [illegible] definite [illegible] with great confidence [illegible] particularly as pertaining to the [illegible] and different conditions elsewhere. The evidence, however, [illegible]

So far the operating side of the problem alone has been [illegible]. The financial aspects are even more difficult to pass judgment upon with the available data.

[illegible] competent and experienced sanitary engineer to make a conclusive report based on the experience of the two plants now in operation. Such report would at least apply to conditions similar to those under which these plants are operating, though of course any new proposition would have to be considered on its own merits.

The experimental plant established at Crossness, a suburb of London, by the original inventor, W. Webster, in 1889, and which was identical in principle with those of today, though different in certain details, seems never to have led to any further application of the principle, though all the obtainable evidence is to the effect that it was successful in its operation. The further fact that during the twenty years following in which so many and such costly experiments were made in sewage purification, the process was never further developed by sanitary engineers is significant.

On the other hand, weight must be given to statements that the Santa Monica plant has been enlarged and that Oklahoma City is constructing a second plant with a capacity of 2,250,000 gallons. It is also to be noted that present-day purification methods are much more costly both in fixed and operating charges than those of 20 years ago and hence this system would be in a better position to compete with them. Again, the fact that sanitary engineers are not usually electrical engineers may have induced them in the past to favor methods which were more familiar to them.

The following cost data are taken from the reports published in the electrical press.

First cost of Santa Monica plant (2 flumes, 550,000 gal.) including pumps, buildings, and forebay, $18,000. Monthly expenses of operating, including pumping, $400. Cost of energy for the year 1909, $159.95, at three cents per kilowatt-hour. Two men are employed at $85 per month but they do other work for the city. The proposal for a filtration plant to do the same work was:

First cost of Oklahoma City plant, $16,000 (cut about 20 per cent. below this figure in order to introduce the plants).

Operating Costs.

	Per annum.	Per mil. gals.
Current (at 5 cents)	$700.50	$ 2.50
Attendant	660.00	2.41
Lights	40.00	.15
Renewal of plates	200.00	.73
Depreciation	100.00	.37
Interest, 5 per cent	800.00	2.92
	$2,500.50	$ 9.17
Sinking fund, (5%, 20 years)...	1,000.00	3.64
	$3,509.50	$12.81

Another process, also invented by Webster, which employs electricity and was extensively exploited in 1894, makes use of an antiseptic solution produced electrolytically from sea water or salt solution. It seems to have been conclusively demonstrated that such solution has no advantage over antiseptics bought from manufacturing chemists and is more costly for ordinary conditions. Improvements in this method recently suggested by W. B. Ball, but still in an experimental stage may alter this situation.

Another interesting development is the use of ozone electrically produced for sewage purification. It is claimed that [illegible] grams of ozone can now be produced per kilowatt hour by the Mosher ozonizer and that a contract for a complete sewage treatment plant has been entered into with the city of [illegible], N.J. No data are at present available.

In conclusion it appears that the verdict for the electrolytic purification of sewage must be at the present time "Not proven. [illegible]."

HARBOR IMPROVEMENTS AT ST. JOHN'S, N.B.

St. John's activity during the last year is due chiefly to the enormous expenditures being made on harbor works, but there is also an increase in the number of factories. The Norton Griffiths Dredging Company are bringing in a fleet of powerful dredges to work in Courtenay Bay, and there are already five dredges and a stone lifter at work in the western harbor and the channel. The Norton Griffiths Company are steadily enlarging their mammoth plant at the site of the breakwater and dry dock in Courtenay Bay, and work will be continued throughout the winter. At West St. John work has been begun on the foundation of the Canadian Pacific Railway grain elevator, and this work will be steadily continued throughout the winter, as well as also the work of constructing new wharves at that point.

The Canadian Pacific Railway finds it necessary to erect a large addition to its office building at West St. John. It has also asked the city for a considerable strip of land at Fairville for an extension of its railway yards. The Intercolonial Railway is adding to its yard capacity storage room for 300 additional cars. The street railway company will extend its line in the direction of East St. John and its electric light system the whole way

Interesting developments are taking place at Coldbrook, three miles out on the line of the Intercolonial Railway. Formerly there were extensive rolling mills at this point, and it was quite an industrial centre, but of late years industry there had ceased. The Maritime Motor Car Company is building an automobile factory to be ready by February 1st, and has discovered on its property a deposit of fine brick clay and a brick-making establishment will be added. The Coldbrook Realty and Development Company, which has planned a garden suburb there, will erect before spring several cottages for workpeople.

USE OF PEAT IN GAS PRODUCERS.

On account of the lack of suitable coal deposits in the central Provinces of Canada and the rapidly decreasing supply of wood, the Canadian Government has taken an active interest in the exploitation of peat bogs with the view of developing from these deposits a fuel supply independent of outside sources.

Not only has the use of peat as fuel been considered, but the question of its utilization for producer gas has also received attention. A producer has been installed at the Fuel-testing Station, Ottawa, and exhaustive investigations have been conducted to determine the suitability of peat for this purpose. It is stated that very gratifying results have been obtained.

Mr. B. F. Haanel, chief engineer of the Division of Fuels and Fuel-testing of the Department of Mines, Canada, who discussed these results in a paper presented before the Eighth International Congress of Applied Chemistry, explains that the process used in manufacturing peat fuel mechanically treats the raw peat and utilizes the sun's heat for drying.

The raw peat is fed into a pulping mill consisting of a series of revolving knives rotating against fixed knives. By this treatment a homogeneous mass is secured, and by breaking the cell walls the contained moisture evaporates more easily. After thorough pulping the peat is taken to the drying field, spread out, cut into blocks of suitable size and thoroughly dried. The moisture content is reduced by this process to 25 or 30 per cent., below which it is not considered economical to proceed.

On account of the hand labor involved the estimated cost of one ton of peat fuel is about $2, including interest on capital invested and a profit of 15 cents per ton. To put the industry on a paying basis it is recommended that the excavation and spreading should be performed automatically and on a large scale. A plant is now being installed to meet these requirements.

On account of the low heating value of peat fuel it is not considered suitable for steam raising, though well adapted for producer gas production.

The high percentage of nitrogen in Canadian peat thus far examined peculiarly adapts it for plants designed for ammonia recovery. The nitrogen in the peat is recovered as ammonia sulphate, for which there is a large demand in the fertilizer industry.

However, the common type of producer employed for peat is not constructed for the recovery of by-products, but rather to burn the fuel with the highest possible thermal efficiency. The Körting producer erected at the Fuel-testing Station, Ottawa, is of this type, and is designed not only to obtain the complete gasification of all the combustible components in the peat, but to destroy rather than recover any of the by-products.

It was found necessary to modify the type of producer in some details before economic results were obtained but without going into details the investigation, in the opinion of Mr. Haanel, has proved that the peats tested are an economic source of power.

THE EFFICIENCIES OF A HYDRO-ELECTRIC SYSTEM.

The accompanying table gives an outline of the losses and efficiencies, for 1911, of the Seattle Municipal Light and Power Plant. This matter was presented by J. D. Ross in a recent paper before the Pacific Coast section of the American Institute of Electrical Engineers. The figures given are believed to approximate closely the true values, since great care was taken in the measurements made by frequently calibrated instruments. All results have been checked in as many ways as possible.

Outline of Losses and Efficiencies for 1911, Seattle Municipal Light and Power Plant.

	Per cent all-day efficiency	Total 1911 input, kw-hr	Average 1911 input, kw	Total 1911 loss, kw-hr	Average 1911 loss, kw	Per cent loss	Per cent of penstock input	Per cent of total loss

The Seattle plant is a hydro-electric system delivering water to two 1,500 kw. Pelton units and two 5,000 kw. turbine units under 600 ft. head through two pipes approximately [illegible] miles long, one of which is [illegible], and the other 49 ins. inside diameter. The current is transmitted at 60,000 volts through two lines to Seattle, a distance of 38.7 miles, and is there distributed at 13,000 and 2,400 volts for use by approximately 20,000 customers and for the city street lighting.

SMELTING COBALT-SILVER ORES BY VACUUM ELECTRIC FURNACE.

The problem of smelting the difficult arsenides in the vacuum electric furnace was discussed recently by Colin G. Fink of the General Electric Co. at the April meeting of the American Electrochemical Society. He described experiments carried out with the idea of ascertaining whether ores, particularly complex or "rebellious" ores, such as smaltite, containing arsenic, sulphur, phosphorus or similar elements, could be more readily and more economically reduced in a vacuum.

Experiments were made with the treatment of smaltite ore from Canada, in a vacuum electric furnace. Simple heating of the ore without any additions was first tried, but without great success. Up to temperatures of about 1,500° C., but 40% of the arsenic present in the ore is expelled. It is only after exceeding the melting point of cobalt that a further reduction of the arsenic is brought about. If silver is present in the ore, it distils out at about 1,300° and can be collected in a chamber fitted into the cooler portions of the furnace.

Since it proved difficult to reduce the ore by intense heating, Dr. Fink tried the effect of additions. Of all those he tried the most effective was calcium carbide or a mixture of calcium carbonate and carbon.

With a mixture of 20 parts $CaCo_3$ and 6.4 CaC_2 and 30 parts ore, when the charge was heated at 1,500° C. for 1½ hours, the arsenic in the product was 2.1%. In this case the calcium oxide and carbide react with each other:

$$2CaO + CaC_2 = 3Ca + 2CO.$$

And the metallic calcium combines with the arsenic:

$$CoAs_2 + 3Ca = Ca_3As_2 + Co.$$

Calcium arsenide separates from the reduced cobalt as slag and part of the arsenic is volatilized.

The second part of Dr. Fink's paper describes experiments made with Nipissing ore. One lot analyzed 9.65% cobalt, 4.65% nickel, 28.65% arsenic, 18.06% silver, 39% gangue.

The behavior of this ore was similar to that of the smaltite ore. When heated alone a splendid separation was obtained into crude silver (83% ag), metal speiss, and slag.

The dividing line between silver and speiss is exceedingly sharp in the vacuum furnace product. A number of comparative runs were made in a carbon resistance furnace of the Moissan type, the gas pressure in the furnace being one atmosphere. Although a separation of the crude silver, speiss and slag was obtained, it was very incomplete and the volume of arsenic fumes evolved was very annoying.

In the vacuum furnace it was found convenient to make the runs in two stages. During the first stage the temperature was maintained at about 1,250° to 1,350° for 2 hours. At the end of this time, instead of cooling down or tapping off the three components, the temperature was still further increased to 1,550° to 1,600° and the charge kept there for about 3 hours. At this temperature the silver distilled out, leaving the [illegible] and slag behind.

The composition of the charge at the end of the first stage [illegible] slag, 20%, and arsenic (distillate) 8.5%. The addition of 5 [illegible] allowing the gases to escape readily. The crude silver of [illegible]

IMPROVEMENTS IN ACETYLENE GAS GENERATION.

Acetylene is a gas that has been known to chemists for many years, but its recent introduction before the public is due almost to an accident. Some years ago a Canadian chemical experimenter, according to report, was treating a mixture of coke and lime with the electric arc in a confined crucible; just what he was hoping would result from this fusion is not stated, but the results in his first estimation were a failure. A drop of water happened to fall on the discarded mixture and this is the story of the discovery of calcium carbide.

The daily and scientific press of that day immediately seized the discovery as the philosophers stone and simple, sure directions for the construction of an acetylene generator appeared in almost every technical paper; but they failed to realize what every veteran inventor must come to understand, that there is a long stride between laboratory discovery and a complete successful marketing of the commercial product. Companies that were to manufacture acetylene generators were organized all over the world, but very few have thrived. Of some seventy concerns organized in the city of Toronto for this purpose three are still in existence.

All these generators depend on one of two principles; either the calcium carbide was brought to the water or the water was brought to the calcium carbide. The gas was evolved in tremendous volumes absolutely raw and unpurified, and in this condition was burned on a tip so arranged that a draught of air was created that kept the burner from clogging, for acetylene is very rich in carbon.

An English company taking the name of Carbic, Limited, have revolutionized acetylene gas generation by improving the means of applying the calcium carbide to the water instead of attempting any great novelties in the generator, as so many companies have.

Under the patents of this company calcium carbide, ground to the size of small beans, is mixed with two common and inexpensive substances and then heated to 120 degrees F. The sticky mass which results is placed in the die of a power press and forced to assume the shape of a brick or tablet and when this is cool it is ready to be packed and shipped.

There are many advantages in using calcium carbide under this form of which the following are a few.

There is no ash left; all the by-products are in the form of a thin sludge which may be entirely removed by opening a cock at the bottom of the generator.

The cake does not deteriorate when the generator is not operating.

The cake dissolves away from the bottom.

The ingredients in the cake serve as a purifier and the gas comes off very pure and almost odorless.

The generator does not heat.

The gas is generated very slowly.

The cakes may be left exposed to the air for several days without damage.

The cakes are very low in price and quite light for shipping.

A branch of this company has been established in Toronto, and will manufacture the products as well as a fine line of generators. Among the generators to be manufactured will be [illegible] night lamp that gives a powerful white light at an exceedingly low cost of operation, and a generator to be used in the production of acetylene for metal welding in conjunction with oxygen. Other lamps for specific purposes will also be manufactured. Reference will be made to the other plants of the company in a future number of The Canadian Engineer.

REPORT ON RAILWAY ENTRANCES TO CITY OF OTTAWA.

A report was made some time ago by Mr. W. F. Tye, Consulting Engineer, and Mr. N. J. Kerr, City Engineer, on the proposal of the Canadian Pacific Railway to enter the city of Ottawa. An abstract of the report follows:—

The city of Ottawa, lying in the horseshoe curve formed by the Ottawa and Rideau Rivers, is curiously hemmed in both by nature and art. The rivers, canals, and railways form three distinct barriers to the city's progress. The outer barrier, formed by the Ottawa and Rideau Rivers, has, independent of the railways, only eight outlets in a distance of nine miles, namely: the Chaudiere, Interprovincial, Sussex Street, Minto, St. Patrick's, Cummings', Hurdman, and Bank Street Bridges. The second barrier, formed by the Ottawa River and Rideau Canal, has only six outlets in six miles, namely: the Chaudiere, Wellington-Sparks Street, Laurier Avenue, Cartier Street, Bank Street, and Bronson Avenue Bridges. The third barrier, to a great extent the same as the second, is formed by the Ottawa River, Rideau Canal, and the Isabella Street line of the Grand Trunk Railway, and has only six outlets in five miles.

The Ottawa River must always remain a deadline to Ottawa's growth in that direction, and can only be crossed by expensive bridges. The Rideau River has not so far proved a serious obstacle, as it is at too great a distance, but it will only be a few years with Ottawa's present rate of growth until many bridges must be constructed to give access to the lands beyond.

The growth of the city has been rapid. The annual report of the Assessment Department shows the population since 1881 to have been as follows:—

Year.	Population.	Increase %.
1881	25,633	
1891	43,229	68.6
1901	60,689	40.4
1902	61,151	
1903	61,597	
1904	63,234	
1905	65,120	
1906	67,572	
1907	76,260	
1908	80,284	
1909	83,360	
1910	86,106	41.8

In twenty-nine years the growth of the city has been 60,473, or equal to the whole population in 1901. It seems reasonably safe to assume that the rate of increase for the last ten years will be maintained for some time to come, and that the population in 1920 will be at least 125,000. If so, the area between the Isabella Street branch of the Grand Trunk Railway and the Rideau River should be completely built up.

The Rideau Canal and the Isabella Street line of the Grand Trunk Railway are at the present time seriously impeding the city's growth. This can be appreciated by noting the very much superior class of buildings on the city side of the Rideau Canal as compared with the very poor class on the other side, and noting a considerable growth at Ottawa East and Ottawa South, where bridges have already been constructed across the canal, and the almost entire absence of buildings between these points where no bridges have so far been constructed. A poor class of buildings and an absence of substantial growth is also to be seen adjoining the Isabella Street line of the Grand Trunk Railway. Both the canal and railway should undoubtedly be diverted to locations where they will be a benefit to the city, and not a detriment as they now are.

The railways, for the convenience of the public, must reach the heart of the city, which is now and probably always will be in the vicinity of the Parliament Buildings. The valley in which the Rideau Canal has been constructed forms the natural access to this portion of the city; and the railways may be located in this valley so as to give the greatest good to the city with the minimum amount of inconvenience. Streets, crossing from one side of this valley to the other, must of necessity be carried on high-level bridges, and the presence of the railways underneath will not seriously add to their cost.

The manufacturing district between the Ottawa and Rideau Rivers is now and probably will remain in the vicinity of the Chaudiere Falls. The future extensions will depend on the location of such connections as Ottawa will have with the Georgian Bay Canal, but it is almost certain that such extensions will be to the westward. Railway facilities must, of course, be given to this manufacturing district, and the problem which now confronts the city is to so connect these two districts by rail as to give the maximum of efficiency to the railways with the minimum of inconvenience to the city.

Recommendations.—The following recommendations are made on an assumption that assurance can be had from the Dominion Government that the Georgian Bay Canal will be constructed in the reasonably near future.

1st—That the Rideau Canal through the city be moved from its present location to a new location in the western portion of the city approximately as shown on the maps, and that it be rebuilt to the same standard as the Georgian Bay Canal, and to a connection with it.

2nd—That a Railway Reserve be established from the deep cut on the Rideau Canal to the Sparks Street bridge. This reserve to consist of the canal bed and a strip 55 ft. wide, on the west side of the canal from the deep cut to Laurier Avenue, and all the canal lands, exclusive of streets, as shown on the plan, from Laurier Avenue to Sparks Street. This reserve south of Laurier Avenue would be 135 ft. wide sufficient for nine tracks, and should be used by all steam or electric railways (the Grand Trunk excepted) now or hereafter seeking entrance to Ottawa, on terms to be decided by the Railway Commission.

3rd—That the city give its consent to the construction of a tunnel between the Central and Union Stations.

4th—That the city purchase from the Grand Trunk Railway Company that portion of its Canada Atlantic Railway lying between the east side of Concord Street, in Ottawa East, and a point at or near Breeze Hill Avenue. That the land so purchased be resold for building purposes, or used for an east and west boulevard, to be extended eastward by way of Echo Drive and Gladstone Avenue, Tempelton or Somerset Street, to and across the Rideau River, and westerly in two branches, one to the Richmond Road and one to Carling Avenue.

5th—That the Grand Trunk join in the construction of the Wellington Street tunnel, or be given running rights through it on equitable terms. That its Parry Sound line be carried through the tunnel, over its Canada Atlantic main line from the west portal of the tunnel to a point near Laurel Avenue, thence with a curve to the right to join the present right-of-way near Bayswater Avenue.

6th—That no additional railways be hereafter permitted in the area bounded by the present Rideau Canal, Wellington and Preston Streets, except in the Railway Reserve.

7th—When found necessary by the growth of the city, the grades of the Canadian Pacific, Grand Trunk and Canadian Northern be raised at the crossing of the Rideau River at Hurdman's Bridge to permit of proper subways for streets, drives, etc.

The advantages to the city of such a rearrangement of the traffic arteries seem manifest.

Rideau Canal.—The change in the Rideau Canal would give a deep-draught modern harbor connected with the Georgian Bay Canal, and one which could be extended indefinitely up the present Rideau Canal as occasions demand. A definite location is not shown for this canal, as it would require extensive surveys to actually determine, but it would be somewhere in the vicinty of the route shown.

If the Dominion Government spend from $100,000,000 to $150,000,000 in building the Georgian Bay Canal, it should not hesitate to spend an additional one or two per cent. to get direct connection with the city of Ottawa—the greatest traffic centre between Georgian Bay and Montreal.

Such a modern, deep-draught canal, giving entrance to the city of ocean-going vessels, with branch railways on either bank, with a superabundance of power within easy transmission distances, and large deposits of iron within easy reach, should make a manufacturing centre second in future possibilities to none on the continent.

The present Rideau Canal could be closed with a dam in a line with Main Street and Robert Street, Ottawa East, and the portion between that and Dow's Lake used as a pleasure lake in summer and an open-air skating pond in winter. Streets could be carried over it wherever desired at low cost with a large saving to the city. This would at once increase the value of the land between the canal and river and make it available as a high-class residential district. All of this can be done at an actual saving to the city of over $500,000.

Placing the railways in the proposed reserve and through the tunnel would put them where they would be doing the very least damage possible to the city and giving the most effective service. It would firmly anchor the Canadian Pacific main line to the city of Ottawa. It would give the Canadian Northern, the Canadian Pacific, the electric lines, and all other railways, an entrance to the heart of the city, and convenient to the business and residential districts.

Removing the Grand Trunk Isabella Street line would naturally improve what should be a fine residential district, and materially increase real estate value in the neighborhood. The ultimate cost to the city should not be high. The cost of necessary subways, bridges, etc., estimated at $500,000, would be saved. A portion would be recouped by the sale of the land, and additional taxes from the increased values of real estate would materially reduce, if not completely wipe out, the balance.

The suggested change would give the Grand Trunk an equally good line. Some inconvenience would no doubt be found in the necessary change in the Grand Trunk yards, but the heart of a great city is not a fit and proper place for through yards such as these are. They should be located outside the city, as land in their present location is entirely too valuable for such use.

The proposed line could be laid with grades not to exceed [illegible] per cent., and there are many steeper grades on the branch. The [illegible] that a level crossing of the Chaudiere branch of the Canadian Pacific Railway would be necessary, and [illegible] than Perry [illegible] would be rather heavy.

It is a matter of great importance to the city that a Transcontinental Railway, such as the Canadian Northern, [illegible] and the proposed arrangement will give it as good facilities as either the G.T.R. or the C.P.R. and so put it into direct competition with those roads.

The advantages to the city of an Inter-Urban Electric Railway [illegible] of the city.

With the exception of a few unimportant spurs and the Canadian Pacific Railway through Mechanicsville, the proposed changes would eliminate all level crossings, and put Ottawa in this respect in a better position than any city on this continent.

Alternative.—The foregoing recommendations are based on a well-founded assumption that the Georgian Bay Canal will be built in a reasonable time, and if so built, that the Government will rebuild the outlet of the Rideau Canal as a branch of the Georgian Bay Canal to the same standard as the main canal.

If, on proper representation to the Government, it is found that this canal will not be built for many years, and if it is considered undesirable to close the outlet of the Rideau Canal, we recommend that a strip 107.5 feet in width be taken on the west bank of the canal for a railway reserve from the deep cut to Laurier Avenue, together with all canal lands, exclusive of streets, from Laurier Avenue to Sparks Street, and that the foregoing proposals be modified as shown on the accompanying plans. This modification consists principally in raising the proposed grade through the tunnel between eleven and twelve feet, and continuing the 0.4 per cent. grade to the Union Station, where a lift in the grade of the C.P.R. tracks of one to two feet would be necessary. The only objectionable feature in this recommendation to the railways would be the lift-bridge necessary across the canal at the deep cut.

Objections to Alternative Proposition.—It would be objectionable to the city, however, in a number of ways. It would take an unduly large portion of the driveway. The roof of the tunnel being so much higher would interfere with the new relief sewer at Kent Street, necessitating an inverted syphon. The new grade would be so high at Wellington Street as to make necessary a viaduct, and it would also be difficult to get overhead crossing on the streets between Lett and Broad. Should it be necessary to make a level crossing at Broad Street it is recommended that the railway line be deflected to the north of the station.

The new line to connect with the Interprovincial bridge, as shown on the plan, would occupy an undesirable position. It would pass under the post-office and destroy the Customs abode now between the post-office and canal.

A bridge would be required across the Rideau Canal opposite the new G.T.R. station to permit the present G.T.R. tracks to be connected with the tracks through the tunnel.

This alternative is only recommended in the event of the Georgian Bay Canal not being built, and does not in any way affect our recommendation as to the purchase and removal of the Isabella Street branch of the G.T.R. between Concord Street and Breeze Hill Avenue.

The following maps, plans, etc., accompany this report:—

Map of Ottawa, showing proposed changes.

Plan and profile of the proposed new line from the Central to the Union Stations.

Plan and profile of the alternative new line from the Central to the Union Stations.

Cross sections of the canal and driveway, showing lands to be taken for the proposed Railway Reserve.

Profile of the proposed new G.T.R. connection near Bayswater Avenue.

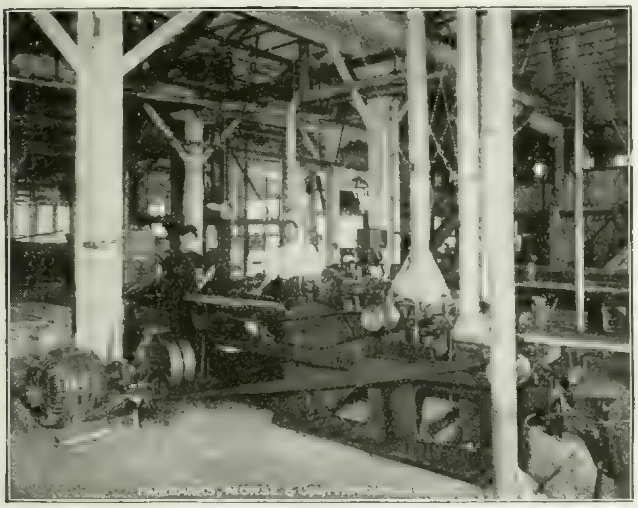
◆

From the British Columbia marine yards at Esquimalt will shortly be launched the steel steamship "Princess Maquinna," the largest vessel ever built in British Columbia waters. She will be employed in the coasting service of the Canadian Pacific Company. The engines and boilers are being built by British manufacturers. The vessel will be fitted as an oil burner.

ELECTRICAL EQUIPMENT OF A LARGE PLANING MILL.

By W. G. Hesser.

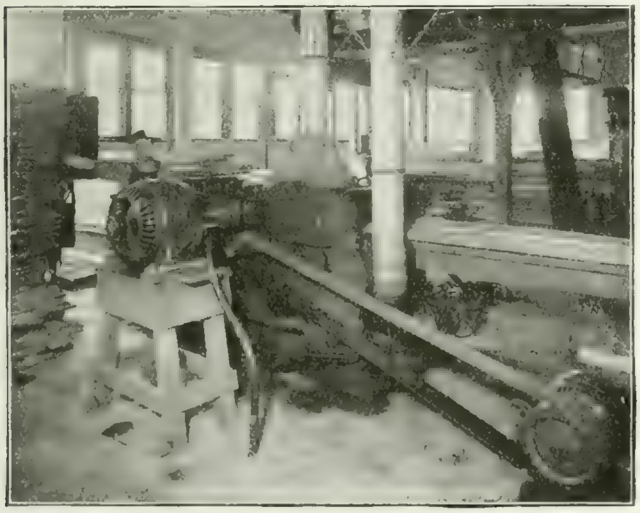
The Louisville Planing Mill and Hard Wood Flooring Co. is incorporated under the State laws of Kentucky for the purpose of manufacturing interior and exterior millwork, sash, doors and high-class stair work. The plant covers approximately 75,000 sq. ft., employs 90 men, and uses about 500,000 ft. of lumber annually, which is manufactured into various kinds of interior and exterior finish.



S. A. Wood Inside Moulder, Driven by 25 H.P. Fairbanks-Morse Motor.

This plant formerly operated its own power plant, but after being destroyed by fire, installed entire new woodworking machinery, operated by motors in the most up-to-date style of drive. Practically, all the machines are direct-connected as shown in the schedule following.

All motors are of the Fairbanks-Morse manufacture, and are 3-phase, 440-volt, 60-cycle. The total horse-power of motors installed is 294, of which 246 H.P. operates on individual drive, and 48 H.P. on group drive as shown in schedule.



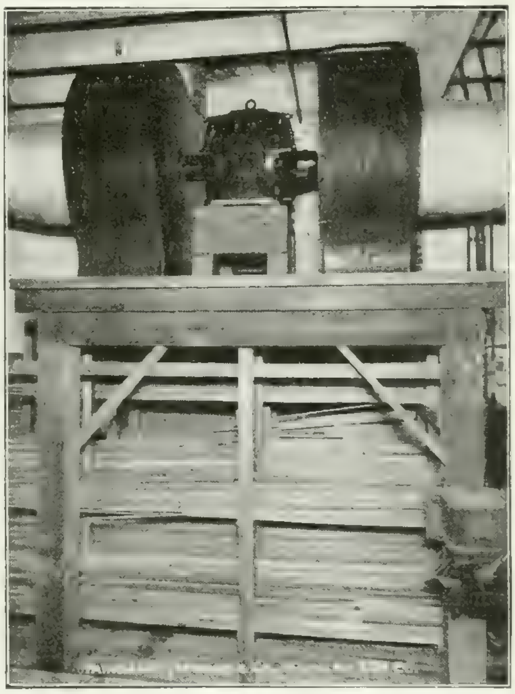
30 x 12 Double Surfacer, Driven by 20 H.P. and 7½ H.P. Fairbanks-Morse Motor.

The principal points of interest in connection with the electrical equipment of this plant is the extreme limit of speed, which is rather unusual for this class of motor. The planers have the motors directly attached to the cylinders, motors operating cylinders at a speed of 3,600 R.P.M., motors being directly connected through flexible couplings.

The double surfacer shown in cut is operated by a 20 H.P. motor at a speed of 3,600 R.P.M., direct connected to the upper cylinder through flexible coupling. The lower cylinders of this machine is belted to a 7½ H.P. 1,750 R.P.M motor.

While there are some few cases where the planer cylinders are operated by induction motors direct connected to cylinders, the direct connecting of motor to the cylinder of the double surfacer is entirely new in this territory, and is proving successful and is giving most excellent satisfaction.

The triple drum sander is driven by a 20 H.P. 570 R.P.M. motor, direct connected through flexible coupling to the countershaft on machine.



70″ Sturtevant Blower, Driven by 40 H.P. Fairbanks-Morse Double End Motor.

The 70″ Sturtevant low-power blower is operated by a 40 H.P. double end motor at 475 R.P.M., the shaft of motor being extended sufficiently for the fan-blades to be directly mounted on each end of shaft. This blower serves readily fifteen motors operating the different machines throughout the plant.

PORT MANN NOT TO BE OCEAN TERMINUS.

Port Mann will be the train assembling centre for the Pacific section, says Sir Donald Mann, at Vancouver. It will be an available centre for the distribution of coal and other freight into the interior, but it will not be our ocean terminus. "We will have our car repair shops and our assembling yards at Port Mann. In all the chief cities of Canada the railways are moving their assembling yards out some distance from the centre of the city. This is being done for several reasons. For one, inside property is too expensive, and another the smoke nuisance caused by shunting has caused many complaints. Most of the yards in Toronto are now five or six miles away from the Union Station. The Grand Trunk has moved its yards out to Mimico and we are moving out also."

COAST TO COAST.

Hamilton, Ont.—The population of this city, according to the [illegible] census, is [illegible], and the assessment $67,000,000.

Moose Jaw, Sask.—The work on the new C.P.R. dam on Manitoba Street East is progressing slowly, but steadily.

Fort George, B.C.—Recently discovered copper deposits found to the west of this town are causing considerable activity among miners residing here.

Winnipeg, Man.—Surveys have been started in order that the line of a proposed railway, to be known as Canada to the Sea, and extending from this city to the Gulf of Mexico, may be ascertained.

Vancouver, B.C.—Vancouver business men, including a few in the immediate surrounding country, have purchased pleasure yachts from Seattle parties, during the last two years, to the amount of over $250,000.

Montreal, Que.—The Canadian Pacific Railway has arrived at an agreement with the owners of the collier Helvetia, which was sunk in the St. Lawrence by the Empress of Britain on July 27th last, and have paid them the sum of $300,000 as compensation.

Ottawa, Ont.—A delegation representing the National Builders' Exchange waited upon Hon. W. T. White with a demand for an imposition of higher duty on every kind of building stone, save rough quarry blocks, coming in from the United States. Consideration was promised the delegates.

Ottawa, Ont.—The medical health department of this municipality recently added a dose of hypochlorite to the water about six times stronger than ordinarily prescribed, and advised the citizens to allow their taps to run in order that the mains might be sterilized. In conjunction with this all dead ends of mains were opened.

Nelson, B.C.—Experiments to show the existence of the platinum group of metals in the ores of the Granite-Poorman mine have been commenced by A. Gordon French and his son, Thomas French, before W. Fleet Robertson, provincial mineralogist. The demonstration is taking place at the Granite-Poorman mill and will probably occupy several days.

Montreal, Que.—The students attending McGill University are working to have a printing press installed for the printing of all the materials required by the various organizations. The faculty heartily endorsed the scheme, but were unable to make financial contributions; the students, however, are making every effort for the installation, and it is probable that such will be made in the near future.

Montreal, Que.—The management of the Canadian Ex[illegible] a new [illegible] transportation of expressage by installing to their service a number of electric trucks. Three are of two-ton capacity and two of one-ton capacity. They have a speed of from 10 to 12 miles an hour, which is more than double the efficiency of the old horse truck, [illegible] miles on a single charge. The large vehicles are 166 inches in length over all [illegible] The others are [illegible] inches in length and [illegible] in width, respectively.

Winnipeg, Man.—[illegible] tons of foodstuffs of all kinds [illegible] by the city health department [illegible] according to the [illegible] The largest [illegible] tons of [illegible] were the other [illegible] During the month the [illegible] were taken [illegible] standard [illegible] in [illegible] and all [illegible] taken for analysis.

Ottawa, Ont.—The Department of Trade and Commerce is issuing a circular letter to the principal boards of trades throughout Canada, asking for information on the possible development of natural resources in each locality. This information, when obtained, will be forwarded to the Imperial Royal Commission, which is now in session in England, with Hon. G. E. Foster as a member. The letter asks for details as to what industries could be suitably developed to work up raw materials which are already produced under profitable conditions, and as to existing obstacles in lack of capital, labor or means of transportation hitherto preventing development of these industries.

Montreal, Que.—A company has been incorporated under the Dominion Companies Act with the title, Siemens Company of Canada, Limited, who will act as sole representatives of the "Associated Siemens Companies" in Canada. The head offices of the new company will be situated in the Transportation Building, Montreal, and the existing offices in Toronto and Winnipeg will be taken over in due course as branch offices. Mr. Arthur S. Herbert, the present Canadian manager, has been appointed general manager; Mr. J. W. Brooks, manager of the Toronto office, and Mr. C. W. Stokes will continue, as hitherto, manager in Winnipeg.

Spokane, Wash.—Plans for the entertainment of delegates to the fifteenth Annual Convention of the American Mining Congress, which meets in Spokane, November 25th to 29th, include a big excursion to the Coeur d'Alene district in Idaho. Civic bodies and owners of the great lead producers will join in perfecting arrangements that will throw the entire district open to inspection. Trips will be made through the big tunnel of the Bunker Hill and Sullivan mine to some of the immense stopes now being mined; to the Morning and other properties of the Federal Mining and Smelting Company, and to the Hercules at Burke. It is expected that fully 500 visitors will be transported on the special train that is scheduled to leave the city early on the morning of the last day of the week. The return will be made either Sunday evening or Monday morning.

Niagara Falls, Ont.—An attempt was made to run a car over the new girder rails laid by the N.S. and T. on the curve at the corner of Erie Avenue and Bridge Street, with the result that one of the large St. Catharines cars was almost derailed. The test showed that the gauge of the track is too wide, the flange of the car wheel which should engage with the flange of the rail being more than an inch from true, and it is probable that the work will have to be done over. The track at that point is entirely completed, and the tearing up and relaying of the rails will involve great additional expense and loss of time. The rails are laid on steel ties, which are firmly embedded in concrete and brick, making it a difficult task to tear them loose. The rail is of the girder type, but different to the rail approved by the city council, in that the flange is narrower, leaving no room for free play of the car wheel flanges. The rail approved by the council had a wider flange and does not turn up at such an acute angle.

◆

CORRECTION.

In the issue of *The Canadian Engineer* of October 10th, page [illegible], in the article on "Briquetting Bituminous Coal," the statement was made that the Inverness Railway and Coal Company are installing a briquetting plant at Inverness, C.B. The context would lead the reader to believe that this plant is of Belgian manufacture. Our attention, however, has been drawn to the fact that this plant is of English make, and we are therefore glad to make this correction.

ESTIMATORS AND ENGINEERS.

Attention is called to the card on another page of this issue of a new engineering firm in Toronto.

The firm, Kortright & Greene, estimating and quantity engineers, will undertake estimating, taking off quantities from plans, foundation reports, supervising, and all branches of engineering for contractors and engineers. There is undoubtedly a great necessity here for such a firm, and the idea of technically trained men with practical experience in this field work, deserves the hearty encouragement of all. Both members of the firm have had wide engineering experience, which, combined with their technical training, thoroughly qualifies them for such work.

◆

PERSONAL.

MR. GEO. WRIGHT, City Engineer of London, Ont., has tendered his resignation to the City Council.

MR. WM. WORTHINGTON, B.A.Sc., has been appointed assistant engineer in charge of sewers for the city of Toronto.

Mr. E. M. HAMILTON is at Cobalt, engaged in completing the new Nipissing mill, which will shortly be put in commission.

DR. WILLIAM B. MUNRO, a native of Almonte, Ont., has been appointed Professor of Municipal Government at Harvard University.

DR. REGINALD A. DALY, a native of Napanee, Ont., has been appointed to the head of the Geological Department of Harvard University.

MR. JOHN P. WAGNER, sales-manager of the Consolidated Expanded Metal Companies, of Pittsburg, Pa., was a visitor to Toronto last week. It will be remembered that we noted in a recent issue that Messrs. Alfred Rogers, Limited, had obtained the exclusive selling-rights in Ontario for the expanded metal manufactured by the above firm. Mr. Wagner is a graduate of the University of Berlin, Germany, and has had a great deal of experience both in engineering design and construction. His work has been located both in Canada and the United States, the Simpson and Globe Buildings in Toronto being representative of the work done here.

John P. Wagner.

MR. G. I. EVANS, Mechanical Engineer of the Canadian Pacific Railway, Montreal, Que., has been appointed Superintendent of the locomotive shops at Angus, Montreal.

MR. J. D. SHIELDS, B.A.Sc., assistant engineer in charge of sewers for the city of Toronto, has tendered his resignation. He is going abroad for a short trip and will then look after his private interests which have necessitated the city's employ.

MR. G. HALL SCOTT, of London, England, and MR. ALBERT BROOKS, Montreal, representatives of Sir John Jackson, Limited, of Edinburgh, are in Victoria to look over the site and complete investigations on which to base a tender for the work on the breakwater.

MR. ALEXANDER ALLAIRE, until recently the manager of the Foundation Company, Limited, with headquarters at Montreal, has been appointed the manager for Western Canada of the Foundation Company, with headquarters at Winnipeg and New York. Mr. R. Chadwick, who was Mr. Allaire's chief assistant at Montreal, steps into the managership of the Montreal office. The western interests of the company have developed to such an extent that it became necessary to open the office in Winnipeg.

Alexander Allaire.

Mr. Allaire is of French descent, was born in Brooklyn, N.Y., and received his engineering education at the Stevens Institute of Technology at Hoboken, N.J. He graduated in mechanical engineering in 1901, and, after four years of practical experience in mechanical work, he joined the Foundation Company in the United States. About two years ago this company decided to start an independent Canadian company. A Federal charter was obtained, and Mr. Allaire was selected as manager of the Canadian company, with offices in the Bank of Ottawa Building, Montreal. A number of important works have been carried out by the Foundation Company, Limited, during the past two years, and the opening of the western office is a natural result of the increased amount of work which has developed in Western Canada.

DR. FRANCIS W. MERCHANT, director of Technical and Industrial Education of Ontario, has gone on an extended tour to Europe to study the technical-school systems in operation there.

MR. J. H. CUNNINGHAM, recently resident engineer, has been appointed superintendent of Extension colliery, in British Columbia, owned by the Canadian Collieries (Dunsmuir), Limited. He succeeds Thomas Russell, resigned.

MR. FRANK KOESTER, Consulting Engineer, has removed his office from 115 Broadway to 50 Church Street, New York. Mr. Koester recently finished the plans for a central asphalt repairing plant of 3,000 square yards daily capacity, for which he was retained by the Borough of Manhattan.

MR. W. F. TYE, President of the Canadian Society of Civil Engineers, has been appointed by the Government to investigate work done in the construction of the National Transcontinental Railway under the old commission. An investigation has been in progress for some months by

George Lynch Staunton, K.C., of Hamilton, and F. P. Gutelius, formerly with the C.P.R.

◆

OBITUARY.

MR. PETER ARNOT, proprietor of the firm of Peter Arnot and Son, is dead; he was well known in engineering and contracting circles. Among the important works executed by him are the sea walls at Sunnyside and the Exhibition grounds in the city of Toronto and the lake front at Hanlan's Point, Toronto Island. He was born at Ashburnham, near Peterboro, in 1849. He entered the contracting business in 1875 with Mr. Charles Robertson as partner; this firm was dissolved in 1905 and Mr. Arnot took over the entire business. He is survived by a widow and several children.

CANADIAN ELECTRICAL ASSOCIATION.—President, A. A. Dion, Ottawa Secretary, T. S. Young, 220 King Street W., Toronto.

CANADIAN FORESTRY ASSOCIATION.—President, John Hendry, Vancouver. Secretary, James Lawler Canadian Building, Ottawa.

CANADIAN GAS ASSOCIATION.—President, Arthur Hewitt, General Manager Consumers' Gas Company, Toronto; John Kelilor, Secretary-Treasurer, Hamilton, Ont.

CANADIAN INDEPENDENT TELEPHONE ASSOCIATION.—President, W. Doan, M.D., Harrietsville, Ont.; Secretary-Treasurer, Francis Dagger, 21 Richmond Street West, Toronto.

THE CANADIAN INSTITUTE.—198 College Street, Toronto. President J. B. Tyrrell; Secretary, Mr. J. Patterson.

CANADIAN MINING INSTITUTE.—Windsor Hotel, Montreal. President, Dr. A. E. Barlow, Montreal; Secretary, H. Mortimer Lamb, Windsor Hotel, Montreal.

CANADIAN PEAT SOCIETY.—President, J. McWilliam, M.D., London, Ont.; Secretary-Treasurer, Arthur J. Forward, B.A., 22 Castle Building, Ottawa, Ont.

THE CANADIAN PUBLIC HEALTH ASSOCIATION.—President, Dr. Charles A. Hodgetts, Ottawa; General Secretary, Major Lorne Drum, Ottawa.

CANADIAN RAILWAY CLUB.—President, A. A. Goodchild; Secretary, James Powell, P.O. Box 7, St. Lambert, near Montreal, P.Q.

CANADIAN STREET RAILWAY ASSOCIATION.—President, Patrick Dubee, Montreal; Secretary, Acton Burrows, 70 Bond Street, Toronto.

CANADIAN SOCIETY OF FOREST ENGINEERS.—President, Dr. Fernow, Toronto.; Secretary, F. W. H. Jacombe, Department of the Interior, Ottawa.

CENTRAL RAILWAY AND ENGINEERING CLUB.—Toronto, President G. Baldwin; Secretary, C. L. Worth, 409 Union Station. Meets third Tuesday each month except June, July and August.

DOMINION LAND SURVEYORS.—President, Mr. R. A. Belanger, Ottawa Secretary-Treasurer, E. M. Dennis, Dept. of the Interior, Ottawa.

EDMONTON ENGINEERING SOCIETY.—President, J. Chalmers; Secretary, B. F. Mitchell, City Engineer's Office, Edmonton, Alberta.

ENGINEERING SOCIETY, TORONTO UNIVERSITY.—President, J. E. Ritchie; Corresponding Secretary, C. C. Rous.

ENGINEERS' CLUB OF MONTREAL.—Secretary, C. M. Strange, 9 Beaver Hall Square, Montreal.

ENGINEERS' CLUB OF TORONTO.—96 King Street West. President Willis Chipman; Secretary, R. B. Wolsey. Meeting every Thursday evening during the fall and winter months.

INSTITUTION OF ELECTRICAL ENGINEERS.—President, Dr. G. Kapp Secretary, P. F. Rowell, Victoria Embankment, London, W.C.; Hon. Secretary-Treasurer for Canada, Lawford Grant, Power Building, Montreal, Que.

INSTITUTION OF MINING AND METALLURGY.—President, Edgar Taylor; Secretary, C. McDermid, London, England. Canadian members of Council:—Prof. F. D. Adams, J. B. Porter, H. E. T. Haultain and W. H. Miller and Messrs W. H. Trewartha-James and J. B. Tyrrell.

INTERNATIONAL ASSOCIATION FOR THE PREVENTION OF SMOKE.—Secretary R. C. Harris, City Hall, Toronto.

MANITOBA ASSOCIATION OF ARCHITECTS.—President, W. Fingland, Winnipeg; Secretary, R. G. Hanford.

MANITOBA LAND SURVEYORS.—President, George McPhillips; Secretary-Treasurer, C. G. Chataway, Winnipeg, Man.

NOVA SCOTIA MINING SOCIETY.—President, T. J. Brown, Sydney Mines, C. B.; Secretary, A. A. Hayward.

NOVA SCOTIA SOCIETY OF ENGINEERS, HALIFAX.—President, J. N. MacKenzie; Secretary, A. R. McCleave, Assistant Road Commissioner's Office, Halifax, N.S.

ONTARIO ASSOCIATION OF ARCHITECTS.—President, C. P. Meredith, [illegible] Secretary, H. [illegible] Moore, [illegible] Toronto.

ONTARIO PROVINCIAL GOOD ROADS ASSOCIATION.—President, [illegible] Hon. Secretary-Treasurer, J. E. Farewell, Whitby, Secretary-Treasurer, G. S. Henry, Oriole.

ONTARIO LAND SURVEYORS' ASSOCIATION.—President, T. B. Speight, Toronto; Secretary, L. V. Rorke, Toronto.

THE PEAT ASSOCIATION OF CANADA.—Secretary, Wm. J. W. Booth, New Drawer, 2263, Main P.O., Montreal.

PROVINCE OF QUEBEC ASSOCIATION OF ARCHITECTS.—Secretary, [illegible] Beaver Hall Square, Montreal.

REGINA ENGINEERING SOCIETY.—President, A. J. McPherson, Regina; Secretary, J. A. [illegible] Victoria Avenue, Regina.

ROYAL ARCHITECTURAL INSTITUTE OF CANADA.—President, H. C. [illegible], Winnipeg, Man.; Hon. Secretary, [illegible], No. 5 Beaver Hall Square, Montreal, Que.

ROYAL ASTRONOMICAL SOCIETY.—President, Prof. Louis B. Stewart, Toronto; Secretary, [illegible], Toronto.

SOCIETY OF CHEMICAL INDUSTRY.—Wallace P. Cohoe, Chairman. Alfred Burton, Toronto, Secretary.

UNDERGRADUATE SOCIETY OF APPLIED SCIENCE, McGILL UNIVERSITY.—President, J. P. McRae; Secretary, H. F. Cole.

WESTERN CANADA IRRIGATION ASSOCIATION.—President, Duncan Marshall, Edmonton, Alta. Permanent Secretary, Norman S. Rankin, P.O. Box [illegible], Calgary, Alta.

WESTERN CANADA RAILWAY CLUB.—President, R. R. Nield; Secretary, W. H. [illegible], P.O. Box [illegible], Winnipeg, Man. Second Monday, except June, July and August, at Winnipeg.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc. Printed forms for the purpose will be furnished upon application.

PLANS AND SPECIFICATIONS ON FILE.

The following Plans (P.) and Specifications (S.) are on file for reference only, unless otherwise noted, at the office of The Canadian Engineer, 62 Church Street, Toronto:—

Bids close		Noted in issue of
10-24	—Construction of about 7¾ miles of Combined Sewers, New Westminster, B.C. ....(P. & S.)	10-10
10-24	—Supply of 10,400 ft. reinforced concrete pipe, New Westminster, B.C. ....(P. & S.)	10-10
10-24	—Supply of 1,660 ft. of 48″ steel pipe, bends and specials, New Westminster, B.C. ...(P. & S.)	10-10

TENDERS.

Cap-a-l'Aigle, P.Q.—Construction of an extension to wharf: Tenders to be received until November 11th, 1912, by R. C. Desrochers, secretary, Department of Public Works, Ottawa. Plans, etc., may be seen at this office, also at the offices of A. R. Decary, Esq., district engineer, Post Office Building, Quebec; J. L. Michaud, Esq., district engineer, Merchants Bank Building, St. James Street, Montreal, and on application to the postmaster at Cap-a-l'Aigle, Que.

Ile aux Coudres, P.Q.—Extension to wharf: Tenders to be received until November 5th, 1912, at the office of R. C. Desrochers, secretary, Department of Public Works, Ottawa. Plans and specifications, etc., may be obtained at this department, also at the offices of A. R. Decary, Esq., district engineer, Post Office Building, Quebec; J. L. Michaud, Esq., district engineer, Merchants Bank Building, Montreal, and on application to the postmaster at Ile aux Coudres, Que.

London, Ont.—Tenders for constructing and erecting a 270 foot span pin-connected Petit truss highway bridge with necessary approach spans, concrete piers and abutments complete, will be received at the office of the city clerk until November 13th, 1912. Plans, etc., at the office of the city engineer. W. E. Robinson, chairman No. 2 committee; George W. Wright, city engineer. (See advt. in Canadian Engineer.)

Ottawa, Ont.—Tenders will be received up to noon on Tuesday, the 12th November, 1912, for the following descriptions of timber: Birch, cedar, spruce, pine, oak, fir, teak, all being for delivery at H.M.C. dockyards, at Halifax, N.S., and Esquimalt, B.C. Forms of tender may be had by application to the Naval Store Officer at either dockyard,, and the office of G. J. Desbarats, Deputy Minister of the Naval Service, Department of the Naval Service.

Quebec, Que.—The Quebec Harbor Commissioners have extended the time for the reception of the tenders for a grain elevator until November 20th, 1912. Raoul Renault, secretary-treasurer. (See advt. in Canadian Engineer.)

Regina, Sask.—Tenders for the construction of drain through Townships 13 and 14, will be received until October 29th, 1912, by H. S. Carpenter, acting deputy minister, Regina, at whose office copies of plan, etc., may be had.

Salmon Arm, B.C.—The engineer has been authorized to call for tenders for the erection of the power house, to be either brick or cement.

Salmon Arm, B.C.—Tenders for the material required for the water supply system will be received until October 15th, at the office of the city clerk, Salmon Arm. Plans, etc., at the office of Messrs. Dutcher, Maxwell & Co., Suite 618 Rogers Building, Vancouver, B.C.

Salmon Arm, B.C.—Tenders for the labor required in the construction of the pipe line and distribution systems for the water supply of this city will be received until October 15th, 1912, at the office of the city clerk. Plans, etc., at the office of Messrs. Dutcher, Maxwell & Co., Suite 618 Rogers Building, Vancouver, and city clerk's office, Salmon Arm, B.C.

St. Boniface, Man.—Tenders for the supply and erection of a variable speed motor and motor-driven pump capable of delivering either 1,000,000 or 1,500,000 imperial gallons per 24 hours, will be received until November 8th, 1912. Plans showing layout and available space may be obtained at the city engineer's office. J. B. Cote, city clerk. (See advt. elsewhere in Canadian Engineer.)

Toronto, Ont.—Tenders addressed to Chairman, Board of Control, City Hall, will be received until noon of October 22nd, 1912, for the construction of asphalt, bitulithic and concrete pavements, concrete curbs, and concrete walks on a number of streets. Specifications may be seen and forms of tenders obtained at the office of the Commissioner of Works, Toronto. G. R. Geary (Mayor), chairman, Board of Control.

Vancouver, B.C.—Tenders will be received until October 15th, 1912, for the construction of that portion of the Canadian Northern Pacific Railway extending from Kamloops, B.C., to points at Vernon, Kelowna and Lumby, B.C., a total distance of approximately 131 miles. The contracts will be let in two divisions, as follows: Kelowna to Vernon and Lumby, 48 miles; Vernon to Kamloops, 83 miles. Tenders to include clearing, grubbing, grading, bridges, trestles, culverts, masonry and fencing. Plans, etc., may be obtained at the office of Mackenzie, Mann & Co., Limited, 719 Metropolitan Building, Vancouver, B.C.

Winnipeg, Man.—Tenders for the manufacture and delivery f.o.b. cars city yards, of a quantity of 20-inch O.D. steel drive pipe with couplings, will be received until October 17th, addressed to the chairman, Board of Control. M. Peterson, secretary, Board of Control office, Winnipeg. Specifications, etc., at the office of the city engineer, 223 James Avenue.

Winnipeg, Man.—Tenders addressed to the chairman, Board of Control, will be received until November 13th, 1912, for the manufacture and delivery of the following apparatus and supplies for the fire department: 2 horse-drawn hose wagons; 2 60-h.p. motor hose wagons; 5,000 feet 2½-inch cotton rubber lined fire hose; 600 feet 3½-inch cotton rubber lined fire hose; 30 fire alarm boxes. Specifications, etc., at the office of the chief of the fire department, central fire station.

Yorkton, Sask.—Tenders for the purchase of a combined automobile truck and extension ladders for fire purposes, will be received by the Fire and Light Committee, until November 4th.

CONTRACTS AWARDED.

Barrie, Ont.—Mr. W. A. Ton, of Collingwood, has been awarded the contract for the alteration and adapting of the public building at this place. Cost will be $19,000.

Brockville, Ont.—A contract for alterations to the Brockville post office, costing $1,450, has been awarded to Mr. Fred W. Clow.

Messrs C. L. McCool and T. H. Moffatt have been awarded the contract for constructing the timber superstructure of a wharf here. The cost will be $15,200.

Dalhousie, N.B.—The Northern Dredging and Construction Co., Limited, will do dredging at this point to the ex- [illegible]

Edmonton, Alta.—Mr. W. R. Eastwood has been awarded a contract to erect a temporary school building at a cost [illegible]

Mr. George Watson has been awarded a contract to erect a temporary school building at a cost of $3,800.

Fort William, Ont.—Contracts for the construction of sewers have been awarded as follows: Edward St. sewer, Messrs. Alto and Jacobson, for $3,595. Francis St. sewer, Messrs. Stewardson Bros., for $1,390.

Kingston, Ont.—Messrs. Jago and Harris, Toronto, have secured the contract for the erection of the thirty mechanics' houses for the Kingston Realties, on its property on Stephen Street.

Little Current, Ont.—The Foundation Company, Limited, Bank of Ottawa Building, Montreal, P.Q., have been awarded the contract for the sub-structure of a bridge from Manitoulin Island to Goat Island, for the Algoma Eastern [illegible] Work has already commenced and it is expected that the foundations will be ready for the erection of steel in the spring of 1913.

Moose Jaw, Sask.—[illegible]

Niagara Falls, Ont.—[illegible]

Nelson, B.C.—[illegible]

Ottawa, Ont.—[illegible]

Ottawa, Ont.—[illegible]

Ottawa, Ont.—The federal cabinet have awarded a contract for the following rolling stock to the Canadian Car and Foundry Company, of Montreal: 500 additional steel-framed box cars; price, $1,210 each. 100 Hart convertible cars of 40 tons capacity. 100 steel underframed platform cars of 80,000 pounds capacity each; price, $1,070. Fifty Otis all-spring dump cars; 20 refrigerator cars; price, $2,058.50 each. One 8,000-gallon tank car; price, $2,695.

Ottawa, Ont.—The federal government have awarded a contract to the Preston Car and Coach Company, Preston, Ont., for the supply of three baggage cars at a cost of $7,500 each. These are for use on the Intercolonial Railway.

Ottawa, Ont.—The municipal board of control have awarded a contract for the supply and erection of a new intake pipe for this city to Messrs. Laurin and Leitch, of Montreal.

Penticton, B.C.—The contract for the construction work on the railway bridge over the Okanagan River has been awarded to Messrs. Butterfield and Armstrong, of Seattle. It will be of steel and will be supported by concrete pillars.

Salmon Arm, B.C.—The city council have awarded the following contracts in connection with electric light power plant: That of the Canadian Westinghouse Company for the supply and erection of the field generator, etc., and the Edmond P. Kay Company, Limited, for the Diesel oil engine.

Summerside, P.E.I.—A contract has been awarded to the Dominion Dredging Company for 150,000 cubic yards of dredging at this point.

Toronto, Ont.—At a meeting of the Property Committee of the Board of Education the following tenders were accepted: Malvern High School, mason work, $23,000, G. T. Gates; carpenter work, $11,600, Cross and Le Drew; plastering, $3,000, Beaver & Co.; roofing, $973, A. Mullhu, Limited; iron stairs, $3,600, Canadian Ornamental Iron Co.

Vernon, B.C.—The contract for a new drill hall has been awarded to Mr. T. E. Crowell, the tender being for $16,811.

Victoria, B.C.—The municipal engineering department acting under instructions from the civic authorities will secure an outfit capable of indicating the conditions of the underground water and gas mains. It is understood that considerable damage has been caused by electrolysis. Ald. Gleason and the city electrician were appointed a committee to secure the apparatus.

RAILWAYS—STEAM AND ELECTRIC.

Guelph, Ont.—A citizen of this city is endeavoring to complete a proposition whereby the interests represented by him will build an electric road from Guelph to Puslinch Lake and Hespeler and the municipal council of this city will hand over the franchise of the railway now operating within the confines of Guelph.

LIGHT, HEAT AND POWER.

Brockville, Ont.—Mr. H. Acres, engineer of the Ottawa Hydro-Electric Commission, after an inspection of the Long Sault dam proposition, has expressed himself as pleased with the situation.

Cranbrook, B.C.—Mr. D. S. Grosscup, of Tacoma, U.S.A., and a party from the United States, have opened negotiations with the [illegible] of the Bull River Power Plant with a view of purchasing the plant.

False Creek, B.C.—The Dominion Government are making arrangements for the erection of a beacon light at this point.

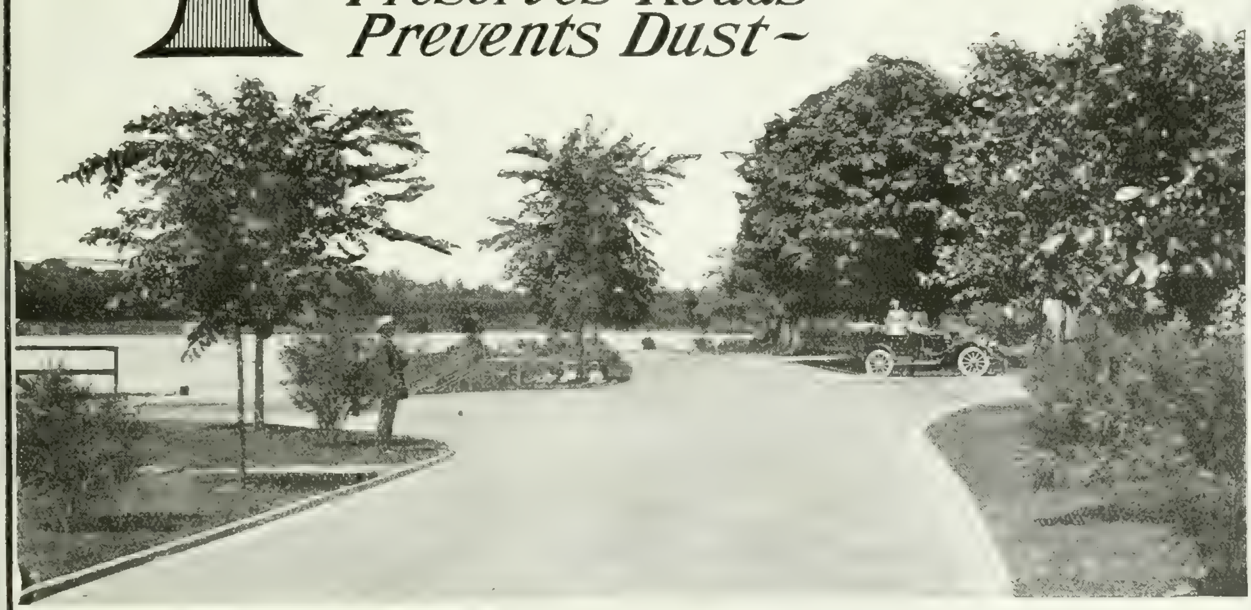
Lindsay, Ont.—The management of the Seymour Power Company are taking steps to interest the farmers of this district in the application of electricity to their daily work.

Toronto, Ont.—The municipal fire and light committee has [illegible] a grant of $[illegible] to be used in the extension of the lighting system of the city.

Township of Yarmouth, Ont.—Seven hundred farmers of this township have petitioned the hydro-electric commission for Niagara power.

Tarvia

Preserves Roads
Prevents Dust~



Section of Government Parkway, Ottawa, Canada, treated with Tarvia B.

The Property Owners' Investigation.

IN the City of St. Thomas, Ont., the property owners on Gladstone Avenue contemplated petitioning the City Council to improve the roadways. They commissioned one of their number to visit various American cities, inspect pavements and make a report. Their investigator, Mr. E. A. Horton, visited various cities in New York and New Jersey. In his report he made the following statements:

> "I saw a 'Tarvia X' road in Rochester which extends from the city to the lake front, a distance of about six miles. It had been in use for eighteen months, and when I saw it, it was in excellent condition, with heavy traffic over it every day. I........inspected a piece of road in Newark........the surface when finished was smooth, and to my mind was one of the finest pieces of road it was my privilege to see. We then inspected another piece of 'Tarvia X' which had been done by the Road Commission two years ago........Constant heavy traffic passes over this road every day, and trucks have loads of from 6 to 8 tons. Steel-tired drays were used with most of their heavy traffic. This piece of road, as I saw it, did not show any wear whatever, and was apparently in as good condition as when it was put down.
>
> "I did not confine my attention to Tarvia roads as I saw (here he mentioned five of the commonest types of road treatment) and every other kind of road that is known.
>
> "I must say after making enquiries from people who were in no way interested, nor did they know I was seeking information, that everyone had a good word to say for the Tarvia road. I have no hesitation in recommending it for use on our street, and at the estimate cost that has been given us, after seeing the many pieces of road that I have seen, I think it is the cheapest road that can be built."

The foregoing is quoted from the St. Thomas, Ont., Journal on February 20th, 1912. Since that date Gladstone Avenue has been constructed with Tarvia X.

Anyone who will investigate the road problem with the same thoroughness will reach similar conclusions. Tarvia is made in three grades:

"Tarvia X" for use in constructing roads and pavements.

"Tarvia A" for hot surface applications.

"Tarvia B" (applied cold) for dust prevention and road preservation.

Booklet describing the latest developments in methods for building tarviated roadways and pavements will be sent free on request. Address our nearest office.

THE PATERSON MANUFACTURING COMPANY, LIMITED
MONTREAL TORONTO WINNIPEG VANCOUVER
THE CARRITTE-PATERSON MANUFACTURING CO., LIMITED
ST. JOHN, N.B. HALIFAX, N.S.

ELECTRICAL INSULATING CONDULETS.

The Canadian General Electric Company, Toronto, are now manufacturing condulets for the protection of electric light and power cables; and in this connection have issued a booklet under the tittle of "Type N Condulet" for stucco work and other decorative positions. This book is not intended to act as a catalogue but contains much information of value to persons engaged in this class of illumination.

◆

SUCTION GAS PLANTS.

The suction gas plant consisting of a gas engine and a gas producer appears to be gaining considerable popularity in Western Canada. The British-Canadian Engineering and Supply Company, Limited, 122 Phœnix Block, Winnipeg, are agents for the Ruston-Proctor producer gas engine and plant, and they have supplied a number of towns throughout the middle west with their equipment. The producer and the engine form together a complete system, the suction of the piston in the engine cylinder drawing from the producer the amount of gas the engine requires. The plant is self-contained, no steam boilers being required and the initial cost of installing the plant is small. The British-Canadian Engineering and Supply Company, Limited, have been awarded contracts for the supplying and erecting of electric lighting plants in the following towns, for Ruston-Proctor producer gas engines and plant, together with all electrical equipment both in and outside the power-house: Gull Lake, Sask., 64 brake h.p.; Hanley, Sask., 50 brake h.p.; Outlook, Sask., 72 brake h.p.; Wadena, Sask., 50 brake h.p.; Rapid City, Man., 50 brake h.p.

◆

A NEW CANADIAN COMPANY.

The C. O. Bartlett & Snow Company, of Canada, Limited, have been granted a Dominion charter to deal in, manufacture and install elevating and conveying machinery, power transmission machinery, engines, boilers, hoisting machiney, brick machinery, garbage reduction and destruction machinery, paint machinery, grain and cereal machinery, and to carry on a general line of engineering, manufacturing and construction work.

The head office of the company has been opened at 282 St. Catherine Street West, Montreal, with Herbert S. Hersey general manager.

[illegible] business of the C. O. Bartlett & Snow Company, of Cleveland, O., and although the connection between the Ohio company and the Canadian company will be very close for some time, the organization and management are entirely [illegible]

The Canadian company has been granted Canadian rights to all patents and licenses owned by the Ohio company and this, taken in connection with the vast engineer- [illegible]

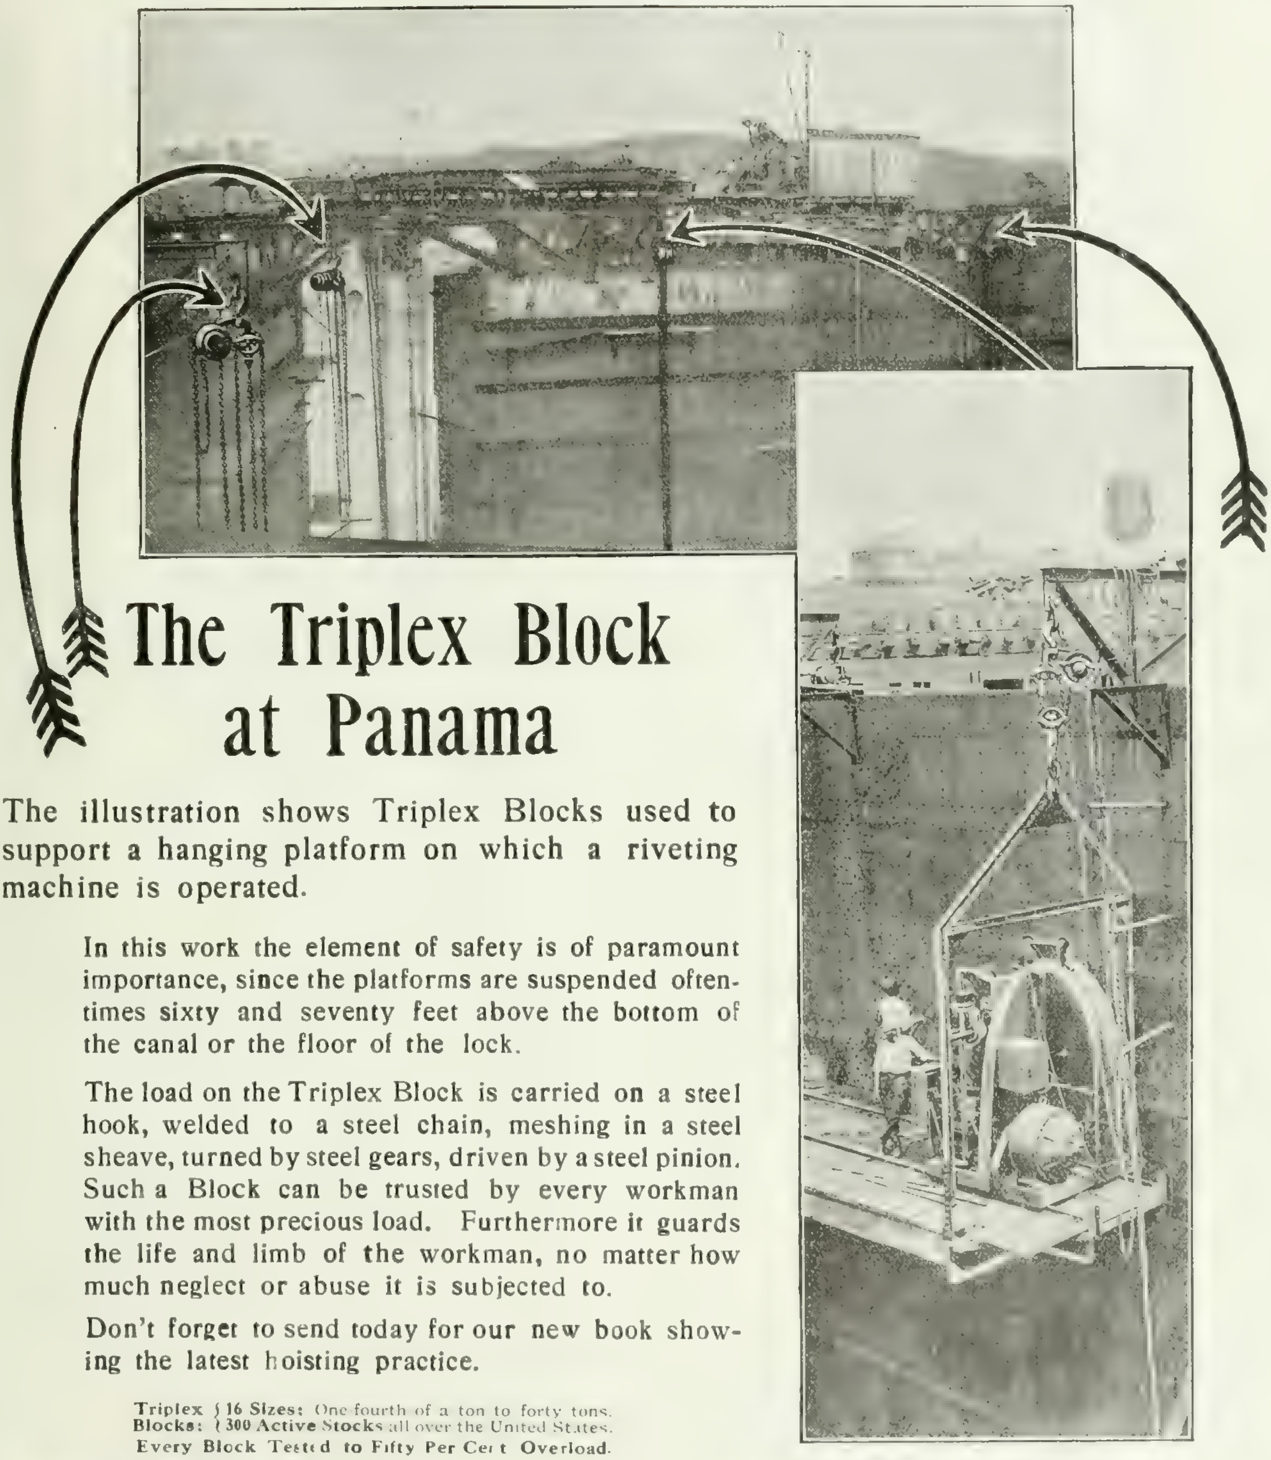
THE TRIPLEX BLOCK



The Triplex Block at Panama

The illustration shows Triplex Blocks used to support a hanging platform on which a riveting machine is operated.

In this work the element of safety is of paramount importance, since the platforms are suspended oftentimes sixty and seventy feet above the bottom of the canal or the floor of the lock.

The load on the Triplex Block is carried on a steel hook, welded to a steel chain, meshing in a steel sheave, turned by steel gears, driven by a steel pinion. Such a Block can be trusted by every workman with the most precious load. Furthermore it guards the life and limb of the workman, no matter how much neglect or abuse it is subjected to.

Don't forget to send today for our new book showing the latest hoisting practice.

Triplex Blocks: { **16 Sizes:** One fourth of a ton to forty tons.
{ **300 Active Stocks** all over the United States.
Every Block Tested to Fifty Per Cent Overload.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA.

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date [illegible] for ready reference and easy filing. Copies of these orders may be secured from The Canadian Engineer for small fee.

17630—October 2—Authorizing C.P.R. to take certain lands for the purpose of enlarging its station grounds at St. Pie, Co. Bagot, Quebec, containing an area of [illegible] hundred and eighty-eight (1,[illegible]88) feet.

17631—October 2—Authorizing C.P.R. to construct extra track across road allowance between Sec. 3, Tp. 15, R. 15, W.P.M., and Sec. 33, Tp. 14, R. 15, W.P.M., at Neepawa, mileage [illegible] on the Minnedosa Subdivision, Manitoba.

17632—September 25—Authorizing Kingston and Pembroke Ry., to construct spur for the North American Smelting Co., Ltd., in city of Kingston.

17633—October [illegible]—Authorizing Toronto Suburban Railway Company to contsruct across the line of the C.P.R., at Mimico River, in Lot 8, Con. B, Tp. Etobicoke, Co. York, Ont., by means of an undercrossing.

17634—October 4—Authorizing G.T.R. to reconstruct four (4) bridges, namely, over Little Sable River, mileage 121.08, Hamilton Creek, mileage 151.18, O'Grady's Creek, mileage 153.28 and over stream, mileage 159.52, on its Middle Division.

17635—September [illegible]—Granting leave to Ottawa Electric Company, to cross, with its wires, the line of C.P.R., at Carleton St., Riverside Park.

17636—October 1—Approving location Toronto, Hamilton and Buffalo Railway Company's passenger station at Silverdale.

17637—October [illegible]—Authorizing Alberta Interurban Ry. to construct across tracks of C.P.R., Calgary-Edmonton Branch, Sec. 13, Tp. 24, R. 1, W. 5 M., [illegible] Southern Alberta, Alta., by means of overhead crossing.

17638—October 4—Approving C.N.O.R. plan of span to replace present timber trestle over Montreal Terminal Ry., Bout de L'Ile, mileage 12 from Montreal, Parish of Pointe aux Trembles, Quebec.

17639—September 26—Authorizing C.N.O.R. to cross tracks of Algoma Eastern Ry. Co., with its main line extension to the Algoma Eastern Ry., on Lot 6, Con. 4, Tp. of McKim, District of Sudbury.

17640—October [illegible]—Extending, until 15th December, 1912, the time within which C.P.R. complete spur for the American Lumber Co., at Sumas Junction, B.C.

17641—October 4—Approving C.P.R. plan showing replacement of double tracking of existing bridge by 30 ft. D. P. G. Span, at bridge 63.3, Lac Du Bonnet Subdivision.

17642—October 4—Authorizing C.P.R. to construct 2 industrial spurs in Block No. 1, which adjoins North Boundary of N.W. ¼ Sec. 34, Tp. 23, R. 1, W. 5 M., city of Calgary, Alta.

17643—October 4—Approving location and style of G.T.R. station at Gobles, Ontario.

17644—October 4—Authorizing G.T.R. to construct branch line for W. Gracey & Sons, town of Barrie, Co. Simcoe, Ontario.

17645—October 4—Authorizing G.T.R. to construct siding for Queen City Oil Co., town of Barrie, Ont.

17646—October 3—Authorizing G.T.P. Branch Lines Company to carry traffic over its Regina-Boundary Branch, Sask., between Regina, mileage 0, and [illegible], mileage [illegible].

17647—October 4—Authorizing city of St. Catharines to construct Berryman St. [illegible] tracks of G.T.R. and N. St. C. & T. Ry.

[illegible] September 4th, 1912, which required derails to be placed on line of B.C. Electric Co., and interlocking [illegible] Vancouver, [illegible] and Southern Ry. Co. [illegible] and cars operating on Nanaimo St., be brought to full stop before making the crossing, at First Ave., Vancouver, B.C.

[illegible] Esquimalt & Nanaimo Ry. to construct [illegible] Victoria.

[illegible] Esquimalt & Nanaimo Ry. to construct [illegible] B.C.

[illegible] Esquimalt & Nanaimo Ry. to construct [illegible] Victoria, B.C.

17661—October 3—Authorizing C.L.O. & W. (C.P.R.) to construct across Scugog St., in town of Bowmanville, Ont., mileage 149.2, and crossing to be protected by gates.

17662—September 3—Authorizing G.T.R. to construct spur for the Battle Creek Toasted Corn Flake Co., Ltd., on Lots 18, 6, 5, 4, and 3, of part of Lot No. 10, Con. "C," Township of London, Ont.

17663—September 7—Authorizing C.P.R. to construct additional track across Clavet & Nelson Sts., by means of undercrossings, and across Stephen St., by extending present overhead bridge, all in city of Port Arthur, Ont.

17664—October 7—Authorizing C.P.R. to construct Bassano to Irricana Branch across fifteen (15) highways from mileage 36.8, near Standard to mileage 50.3, near Hussar, Alberta.

17665—October [illegible]—Approving proposed deviation of Nipissing Central Ry. Co.'s line between Cobalt and North Cobalt, District of Nipissing.

17666—October 7—Approving location Interprovincial and James Bay Ry., from mileage 0 to mileage 10.11, through Parishes of Geandreau and Mercier, Co. Pontiac, Quebec.

17667—October 4—Relieving Kingston and Pembroke from erecting fences along certain portions of its railway.

17668—October 7—Authorizing G.T.R. to take certain lands in St. Antoine Ward, city of Montreal, Quebec, for convenient accommodation of the public and the traffic carried over its railway.

17669—October 7—Directing G.T.R. to protect all shunting movements over switch between its Ry. and Central Ontario Ry. Co. at subway leading from Tp. Murray and' Village of Frankford, to town of Trenton, Ontario, by sending a man ahead.

17670—October 7—Authorizing Algoma Eastern Ry. Co. to construct spur from mileage 9.08 to main line, through Lot 9, Con. 3, in Twp. Snider, to the North Star Mine.

17671—October 7—Authorizing C.P.R. to construct 3 spurs for the Sand & Supplies, Ltd., on Lot 31, Con. 9, Tp. North Dumfries, Co. Waterloo, Ontario, near Ayr.

17672—October 8—Approving revised location Can. Nor. Alta. Ry., through Tp. 46, R. 1, W. 6 M., Alberta, mileage 224.66 to mileage 228.36.

17673—October 8—Approving C.N.R. location through Tps. 4-7, Rgs. 1 East of Principal Meridian, to 2 W. P. M., Manitoba, mileage 0 to mileage 18.08.

17674—October 7—Authorizing C.N.O.R. to construct across public road between Lots 242 and 245, Parish of St. Eustache, Co. of Two Mountains, Que., at station [illegible].

17675—October 7—Authorizing C.N.O.R. to construct across 2 highways in Twp. Ferris, Dist. Nipissing, Ont., on its Montreal-Port Arthur Line.

17676—October 8—Authorizing C.N.O.R. to construct bridge across Ottawa River, at Fitzroy Harbor, Tps. Fitzroy and Onslow, Cos. Carleton and Pontiac, mileage [illegible], west of Ottawa.

17677—October 7—Authorizing G.T.R. to construct siding for James K. Kidd, on Lots 6 and 5, east of Queen St., Mount Bridges, Twp. Caradoc, Ontario.

17678—October 9—Authorizing G.T.R. to construct 6 additional sidings across Robert St., and a public lane running from Elgin St. to Ferguson Ave., city of Hamilton, Ont.

17679—October 8—Approving revised location G.T.P. Branch Lines Co.'s Regina-Boundary Branch from East Line, Sec. 11, Tp. 7, R. 10, to East Line, Sec. 13, Tp. 3, R. 4, W. 2 M., mileage 91.13 to mileage 135.93, Dist. Cannington, Sask.

17680—October 7—Authorizing G.T.R. to construct siding for the Canada Pine Lumber Co., Ltd., on Lot 1, Con. 11, Tp. of Bethune, Dist. of Parry Sound, Ontario.

17681—October 8—Authorizing C.L.O. & W. (C.P.R.) to construct across twenty [illegible] highways from mileage [illegible] to mileage [illegible].

17682—October 9—Authorizing G.T.P. Branch Lines Co. to construct its Regina-Boundary Branch across highway on N.E. ¼, Sec. 11, Tp. 17, R. 20, W. 2 M., at mileage [illegible], Dist. Assiniboia, Sask.

17683—October 7—Approving location C.N.O.R. station grounds at [illegible], Tp. [illegible], Co. Renfrew, Ont., mileage [illegible].

17684—October 8—Extending, Until Nov. 15th, 1912, the time within which G.T.P. Branch Lines Co., complete spur from Melville-Yorkton Branch at a point just north of city limits, Yorkton, Sask.

17685—October 8—Authorizing G.T.P. Branch Lines Co. to construct Brandon Branch across two (2) highways, mileage 18.48 and mileage 14.2, Dist. Brandon, Manitoba.

17686—October 9—Authorizing C.L.O. & W. (C.P.R.) to construct [illegible] between Lots [illegible] and [illegible], Con. 1, Twp. Darlington, Co. Durham, Ontario.

17687—October 9—Approving location C.N.O.R. through Tp. Saltfleet, Co. Wentworth, Ont., mileage [illegible] to mileage [illegible].

17688—October 5—Directing G.T.R. to protect West and Front Sts., in town of [illegible], Ont., by gates and day and night watchmen.

[illegible]—October [illegible]—Approving C.P.R. to construct spur for Consolidated Rubber Company, in city of Winnipeg, Manitoba.

[illegible]—October [illegible]—Extending, until December 31st, 1912, the time within which C.P.R. [illegible] for B.C. [illegible] Ltd., in city of New Westminster, B.C.

[illegible]—October [illegible]—Extending, until June [illegible], 1913, time within which C.P.R. complete railway authorized to be constructed under Order No. [illegible]

[illegible]—October [illegible]—Approving location C.P.R., northwesterly from [illegible] Parish [illegible]

[illegible]—October [illegible]—Authorizing G.T.R. to construct siding for the Pratt & [illegible] Co., Ltd., in city of Brantford, Ont.

Samson Water Wheels

You can always judge a water wheel by the number of successfully operating wheels of that type there are in use—and besides the successful wheels show that the builders have had the right kind of experience, which is important to you.

The Samson wheels in use are developing about *Two Million Horse Power*.

And all the knowledge gained from this extensive experience is back of each new installation.

Send us your next specification.

Peterborough, - Ont.

WINNIPEG LIGHT AND POWER DEPARTMENT.

The civic light and power department of the city of Winnipeg is now considering the necessity of enlarging the capacity of the power-house facilities owing to the rapid industrial development of the city and the consequent demand for power. The horsepower now contracted for to be delivered this fall will necessitate extensions and additional transformer capacity to that provided in the present building. For the spring of 1913 the manager recommends that two extra units be installed. These turbines and alternators should be in operation by summer in 1914. The department is now getting 95 per cent. of the new business of the city, says Manager Glassco, in competition with a private corporation, which before the completion of the municipal plant last year enjoyed a monopoly in the supply of light and power.

◆

GREATER VANCOUVER'S WATER SUPPLY

The water committee of the city council has appointed a sub-committee to go into the matter of the Seymour Creek water supply and to report on same. It is proposed to construct a huge reservoir in the Seymour Creek Valley, the cost of which, with mains, etc., has been placed by the consulting engineers at $632,000. This irrespective of expense in connection with the acquisition of land in the watershed which may be bought to ensure the city's supply of water for ever. The sub-committee will go into the whole problem and will consider what portion, if not all of the land in the valley, is to be purchased. There is talk this week of the Pacific Great Eastern taking a route along the Seymour, as has been suggested, and this will be protested by the city, for it would mean contamination of the water supply if a railway ran close to the reservoir and along the creek from which the water is obtained. If the city secured the whole valley by purchase it would probably exclude the railway. Once this water supply plan is carried into effect, Greater Vancouver should have a complete and efficient system. Not only will there be an abundance of water, but the pressure will be ample in all parts of the city.

Ratepayers have protested because of an insufficient supply and fire insurance underwriters have hinted that pressure is not what it might be. Now that the city has started to act in earnest, it is to be hoped that the work will be carried forward if a satisfactory report is obtained, and not allowed to lapse at the beginning of the year when the usual change will be made in the personnel of the water committee. Even if delays are absent, the scheme cannot be carried into effect for many months, for the work is a very large one.

TENDERS CALLED FOR

CITY OF LONDON, ONTARIO.

Tenders for Wharncliffe Road Highway Bridge Over Thames River.

Sealed proposals addressed to the "Chairman and Members No. 2 Committee," will be received at the Office of the City Clerk until 5 p.m. on Wednesday, November 13th, 1912, for constructing and erecting a 270 foot span pin-connected Petit Truss Highway Bridge with necessary approach spans, concrete piers and abutments complete.

Each bidder shall name lump sum for the various parts of the work as described in the general specification and give price for any deductions or additions to the same and make [illegible] by the City Engineer.

Plans, specifications and form of Tender may be seen or [illegible] from the Office of the City Engineer.

Contractors [illegible] a marked check for Ten per cent (10) of the amount of their bids.

The City reserves the right to reject any or all bids and to accept any bid.

W. L. ROBINSON, GEO. W. WRIGHT,
Chairman No. 2 Committee. City Engineer.

DUNNVILLE WATER COMMISSION.

Tenders will be received up to 9 p.m. on Monday, [illegible] for the laying of approximately [illegible] feet of [illegible] water mains, together with the necessary valves and hydrants.

Further particulars and the conditions of tender to be seen at the office of the Town Engineer, Dunnville, Ont.

Lowest or any tender not necessarily accepted.

A. M. JACKSON,
Town Engineer.

For further Tenders see page 76.

The Canadian Engineer

An Engineering Weekly

BRICK ROADS: MATERIAL, CONSTRUCTION AND MAINTENANCE.*

By THEODORE A. RANDALL, Indianapolis, Ind.†

Permit me to state briefly what I believe constitutes an ideal roadway. It is a pavement which wears smooth and clean and needs no caretaker to keep it in repair, no matter what the character or quality of traffic which passes over it. A pavement which is weather-proof, flood-proof, dirt-proof, wear-proof, and so practically time-proof. A pavement which affords an open and easy highway from country to city every day in the year for any and all sorts of traffic. A roadway over which pleasure vehicles may speed with safety to the driver and without injury to the vehicle or pavement. A roadway over which heavy service trucks may draw loads of several tons at a speed rivalling, if not exceeding, that of the so-called fast freight trains, without damage to the truck or the roadway. A roadway over which a farmer may easily haul with one horse what requires a team on ordinary roads, or with one team as much as two teams will commonly haul. A pavement over which one may journey in comfort, for it is a dustless pavement.

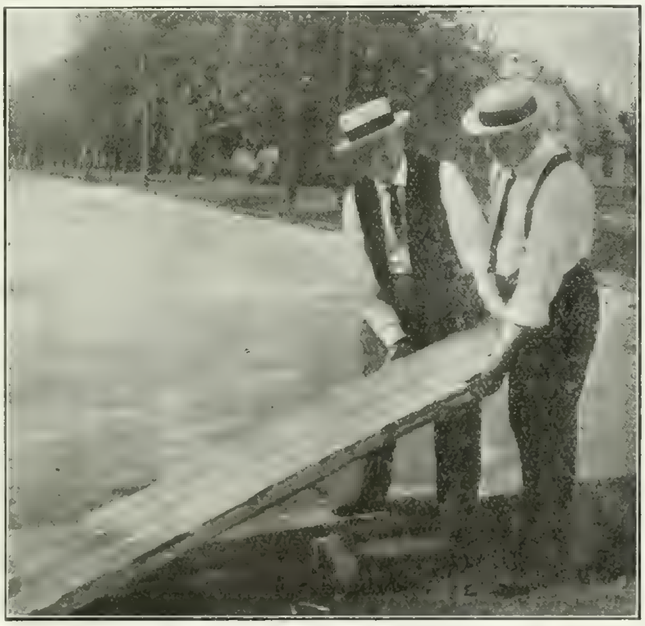

Fig. 1.—A Section of Pavement.
This illustrates the perfect application of the cement filler.

That is precisely the kind of a pavement you can construct of vitrified brick, and that, too, at a cost but little more than is now being paid for our temporary roadways. When you consider that the only cost of such a pavement is its first cost, you must admit that ultimately it is the cheapest pavement you can build. I think I can demonstrate to your satisfaction that practically there is no wear on a properly constructed brick roadway. Here is my proof, and if "seeing is believing," it is most convincing.

Eighteen years ago there lived in Sandusky, Ohio, a wise and painstaking engineer, Mr. John W. Miller; may his tribe increase. Under his direction a mile of brick pavement, part city street and part rural road, was laid, extending from the centre of the town out into the suburbs. Over this pavement during all these years has daily passed much traffic. To-day the pavement is perfectly smooth from one end to the other.

Fortunately, while this pavement has been torn up at times for the laying of gas mains, water pipes, etc., it has, luckily, always been replaced as carefully as it was originally laid, so that to-day it is as good as any new pavement. As you know, most pavements are damaged irretrievably by being torn up, but when such work is done properly, no harm is done to a brick pavement, as demonstrated in this case. During these eighteen years not one dollar has been spent on this pavement for repairs, yet it is still an ideal roadway and bids fair to continue such for another twenty years, or perhaps twice that length of time.

A portion of the main business street of Sandusky was paved the same year (1904) as the other roadway, and with brick of the same grade, but evidently with much less care in the method of construction. To-day, it is a rough and undesirable pavement. This pavement was laid under the same specifications as the good pavement, but as I will show you, some minor but very essential details of construction were carelessly slighted. Mr. Will. P. Blair, secretary of the National Paving Brick Manufacturers' Association, of Cleveland, Ohio, and others who have been studying this subject for some years, determined if possible to learn the real cause of failure in one pavement and the remarkable success in the other. Accordingly, experts recently visited Sandusky and with the co-operation of the city engineer, had a stretch of some fifty square feet of each pavement, the good and the poor, taken up.

The good pavement was perfectly bonded from top to bottom, every course of brick was intact, just as when it was first laid. The foundation was right to begin with, and there was a two-inch sand cushion, thoroughly compressed, affording a smooth, even bed for the brick, and insuring a comparatively noiseless pavement. The cement filler had been so applied that both sides and ends of each and every brick was imbedded in it. You will see by the pictures that the brick and cement formed a solid mass, making the pavement monolithic in character. The result was a perfectly smooth, unbroken surface. From one end of the street to the other, there has been no chipping of brick, or disintegration of the cement filler or binder. A closer inspection of this mile of eighteen-year-old pavement made late in August did not disclose a single defect. The traffic over this pavement has had no perceptible effect upon it, the pavement showing scarcely any wear at all. If left undisturbed this pavement will be just as good at the end of another eighteen years, without a dollar of expense for up-keep.

---

*Abstract of a Lecture delivered before the American Road Congress at Atlantic City, N.J., October 8th, 1912.

†Secretary National Brick Manufacturers' Association.

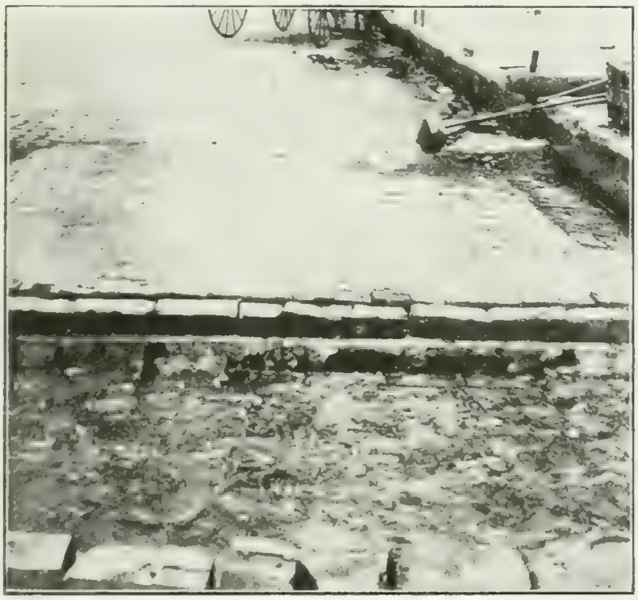

Fig. 2.—A Cut in Pavement.

Showing the imperfect application of the cement filler to which is due the uneven wearing quality of the pavement.

The section of the poor pavement taken up disclosed the secret of its failure, if a pavement can be called a failure which, after eighteen years of use, is, though rough, still doing service, with no expense incurred for repairs. As a fact, it is a failure only by comparison with the perfect pavement. The same grade of brick was used in each pavement, and the traffic is much the same on each street. Why the difference? The answer is easy. It is in the careless construction of one, and the careful construction of the other.

In the good pavement, the cement filler was properly applied. In the poor pavement, not half of the brick were imbedded in the cement. Some of the brick had cement on one end, and not on the other; some of the brick had cement on the upper portion and little, or none, on the lower, and vice versâ. In some small portions of the removed pavement the cement was properly applied. In such portions the [illegible] [illegible] [illegible]; where there was little or no cement, the pavement was the roughest. To my mind, this investigation solves the mystery of good and poor brick pavements. Scientists are at work on the problem and in time a full report of the finding will be made public. I feel [illegible] that the result will justify the opinion I have expressed.

[illegible] have learned how to build brick roadways in Ohio. Every detail of construction is looked after carefully, no [illegible] of the work is neglected, and as a result the roads are so perfect that it [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] [illegible] hundred miles of brick roads in Cuyahoga county alone, and those who use them constantly and appreciate their excellence and economy, [illegible] [illegible] [illegible] pavements and brick pavements [illegible].

Ohio is not alone in appreciation of good brick roads. They are being built in other States. New York, for instance, [illegible] made a fine start. [illegible] has about one hundred miles of these brick roads in the vicinity of Buffalo, and the State Highway Department is building about one hundred additional miles this year at other points, and when the efficiency and economy of these roads have been demonstrated by actual use, the taxpayers of the Empire State will become veritable Oliver Twists in their demand for more of the same sort. It is estimated that $50,000,000 have been expended in New York State alone on temporary roadways. Think of the many miles of permanent brick roads this sum would build. There is a vast difference between a roadway that must be looked after and repaired constantly, and these brick roadways which cost nothing at all if once properly constructed.

The proper construction of a brick paved roadway is a simple matter. In general, the requirements are the same as maintain in the building of any good road.

1. Proper drainage.

2. The careful compaction of the roadbed to a grade corresponding with that of a finished street.

3. A concrete foundation in the colder climates, and on soils of slow drainage.

4. A sand bed, two inches in depth evenly compressed, intervening and immediately underneath the brick.

5. Laying the brick best edge up, with lugs lying in in the same direction.

6. Rolling the brick to an even surface.

7. Application of the cement filler in proportion of one to one.

8. Protecting the filler from too rapid setting.

A properly constructed vitrified brick roadway is the ideal highway. Its merits summarized are:

It is easily built.
It is economical as to first cost.
It costs nothing for maintenance.
It is most satisfactory in use.
It is the most sanitary pavement known.

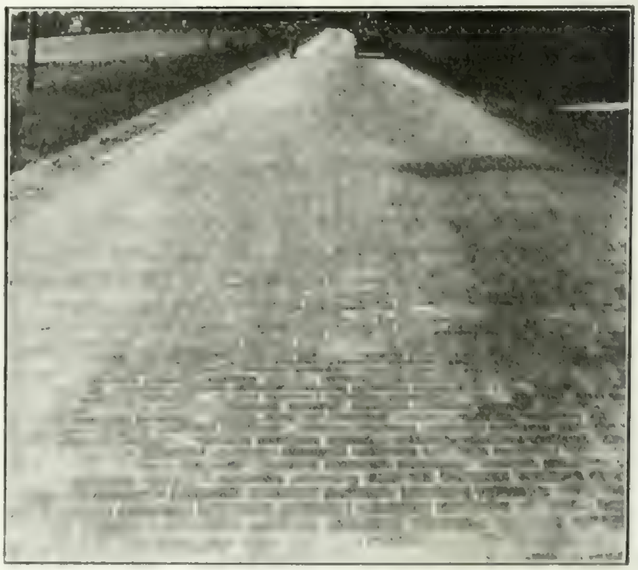

Fig. 3.—Glenwood Road.

Six and one half miles out from Buffalo, N.Y. Wire cut lug brick being used.

It affords the least traction resistance.

It is not a slippery pavement even when wet.

It is adaptable to all climates and all conditions of soil.

It is not an experiment, but a demonstrated fact.

It may be seen and inspected, hundreds of miles of it, in actual use, successfully withstanding excessive traffic.

Its affirmative merits are many and, when the truth is told, there is not one single objection that can be urged against its use for the heavy travelled highways of this country.

If you like speed, you can have it with no "Thank-you-ma'ams" to jar you. If you enjoy beautiful pastoral scenery, you will be delighted. You will be surprised by one feature of these brick-paved country roads—their cleanliness. It is not an uncommon thing for visitors making such a trip for the first time to ask how often the roads are swept. The answer is, "They are swept constantly, but Dame Nature does the sweeping, and she uses no broom." The wind keeps them as clean as the dear old board walk out here that we all love and enjoy.

If, after being convinced, as you will be by such a trip, that the brick-paved roadway is the ideal roadway, and you want to build them in your own district, the National Paving Brick Manufacturers' Association will make it easy for you by supplying you free of charge with complete specifications in which every detail of construction is set forth in plain terms, so that any engineer or road builder can readily comprehend all that is required. If, however, any uncertainty arises, all you need do is to write the National Paving Brick Manufacturers' Association, which is an organization of boosters, which is boosting by methods of education instead of by use of boodle.

In time, brick roads will become universal throughout this country, for there is an abundance of raw materials, shales, and clays, in almost every State in the Union, from which vitrified brick may be made. In sections where paving brick are not now made they can be shipped in, as transportation charges are not prohibitive. On the contrary, brick and cement can be supplied to almost any district in the land at a reasonable price, and the other materials used are found everywhere almost. Indeed, one of the commendable things about brick roadways is the fact that common labor is used in building them, and home products are chiefly used in their construction. They are not a drain on local capital; on the contrary, they stimulate local business by affording employment for labor at fair wages. In short, brick-paved roadways are desirable and commendable from every view point.

◆

CREOSOTING CROSS-TIES.

The annual replacement of cross-ties in Canadian railway lines is about 10,000,000, according to statistics compiled by the Forestry Branch of the Department of the Interior. The average life of a tie, i.e., seven years, could be prolonged to seventeen years if proper preservative treatment were adopted, and an annual saving of 350 million feet, board measure, of timber, could be effected. This is equivalent to three years' cut of one of the very largest mills in the country.

While the initial expense of creosoting would bring the cost per tie from 58 to 93 cents, it would save $1,400,000 annually.

Since 1910 two timber-treating plants have been established, treating, in 1911, 206,209 ties, or 1.5 per cent. of the total cut.

The number of ties purchased in the Dominion in 1911 was 13,683,770, an increase of 4,469,808, or 48.5 per cent. over 1910.

The rapid development of railways in the western provinces is largely responsible for this increase.

Eighteen kinds of wood were used. Jack pine, with 40 per cent.; tamarack, with 19 per cent.; Douglas fir (used to a very great extent in new electric lines in British Columbia) with 14 per cent., and hemlock, with 12 per cent., were the leaders. A remarkable change is that of cedar, in decreasing from 40 per cent. to 5.4 per cent. of the total.

AN ELECTRIC FOUNTAIN OF UNIQUE DESIGN.

By L. M. Edholm.

In San Diego, California, a unique electric fountain has been constructed to stand in a small park on one of the principal streets of the city. The park faces the U.S. Grant Hotel, a magnificent building, and it was necessary to have the fountain harmonize with the surroundings and be an ornament to the park in the day time as well as night.

Mr. Irving J. Gill,* a well-known western architect, designed the fountain after classic monuments of Greece and Rome, not a cheap imitation, but original ideas used, that would take a prominent place among the old masterpieces in art.

The details, many of which are unique, seem to have been very carefully thought out and planned by Mr. Gill.

In a concrete basin stands a granite pedestal from which rise eight marble columns of the Corinthian order. These support a dome of prismatic glass and bronze on the top of which rests a bronze lantern.

View of Fountain in Operation.

Even in the morning before the flow of water is commenced the structure is one that delights the eye, being well proportioned, graceful, quiet and dignified.

Every day at noon the water is turned on. A small electric pump forces the flow up through the marble columns to a point below the bronze lantern from which it flows over the prismatic glass of the dome. The bronze framework of the dome protrudes and causes the water to cascade and foam. Through a perforated sheet of metal under the dome the water falls downward in a shower between the columns. Eight jets shoot at an angle from the sides of the basin to meet the shower and together the waters dash, gurgling and splashing, upon the pedestal and runs into the basin in eight miniature waterfalls. It gives the strange illusion of water rising from the pedestal and terminating in the foam-covered dome.

As a matter of economy the water returns to the starting point and is used again and again.

At night the lights are turned on and the color display is very artistically arranged. All the jets and overflows are illuminated in the different colors. Holoplane reflectors are used under each cluster of lights and a flasher is worked automatically.

Clusters of colored tungsten lights are placed under the prismatic glass of the dome and the subdued glow showing through the glass and foam gives it a jewel-like effect.

One rather unusual detail which Mr. Gill used in his fountain was his idea that in a work of this kind the centre should be the point of greatest interest, and in order to bring this out, the costliness of the material should increase as the centre was reached.

In this arrangement first came the concrete of the basin, the granite of the pedestal, while next in value the marble columns, the dome of prismatic glass and the bronze lantern at the top and centre, which is the most costly material used in the construction.

The fountain was a gift to the city from Mr. Lewis J. Wild, a wealthy resident of San Diego, and was installed at a cost of $15,000.

The mechanism for operating the lights and the small electric pump which sets the water in motion is concealed in a chamber under the fountain.

Five dollars a day covers the up-keep of the fountain and includes the time of the caretaker of the park, whose services are all that are required for the running of the fountain.

CANADA'S COKE SUPPLY

The industrial value of Canada's coke supply is discussed in The London Financier by Mr. J. Lawrence-Hamilton, M.R.C.S. As neither anthracite nor lignite, when heated, coalesces, they are both incapable of making coke, he says. Bituminous coal, on the other hand, when strongly heated in the absence of air in suitably closed ovens, is gradually decomposed, yielding its water, gases, tar, oils, nitrogenous and volatile compounds, which are, of course, separated and collected.

Bituminous coals thus heated first fire, or melt or soften, and then, as decomposition progresses, they stiffen to produce a hard, light, porous, or cellular, coke, consisting chiefly of carbon combined with the contained ash from the original coal. The cellular or quasi-fossil, sponge-like structure of the coke is produced by the expansion of the heated escaping gases derived from the molten mass.

In blast-furnace smelting for treating mineral ores and metals, coke is superior to coal as charcoal is to wood, because both coke and charcoal are rich in carbon. Hence, to manufacture this class of fuel it is necessary to spend time, trouble and money to convert the coal into coke.

For metallurgical and allied purposes a superior coke is required. Such carefully manufactured coke is strong, hard and does not soften or crumple, so that when burning in the blast furnace it can carry a heavy charge of ore without crushing or melting, which would obstruct the blast and diminish the heat required.

Good coke burns without producing tar, oils or smoke. It posses a high calorific value.

Experiments show, and experts know, that Canadian coke [illegible] chemistry, quality and quantity can successfully compete with the cokes from all other countries and Colonies most of which in the near future will be more or less dependent upon the Dominion's cheap coke [illegible], which is practically inexhaustible. To develop Canadian mines and allied industries, cheap, abundant local coke is necessary. Carbonite, or natural coke, made in nature's own laboratory by [illegible], has not yet been discovered in Canada, where, however, it probably exists in large quantities.

Clean, sparkling, pure, solvent water of Canadian "white coal," washes the previously crushed, sized, screened and [illegible] coal [illegible] to the ordinary methods and machines employed in dressing and concentrating metallic ores.

The commercially valuable materials or products in metallic ores are heavier than the contaminating or containing rock. Coal is the lightest of all important commercial minerals, and its natural adulterants, or impurities, are heavier than the coal itself. In other words, in coal washing, the lighter coal escapes at the top, whilst its impurities, being heavier, are discharged separately at a lower exit. In metallic ore washing the lighter contaminating rock escapes above, whilst the metallic ores are discharged at a lower level.

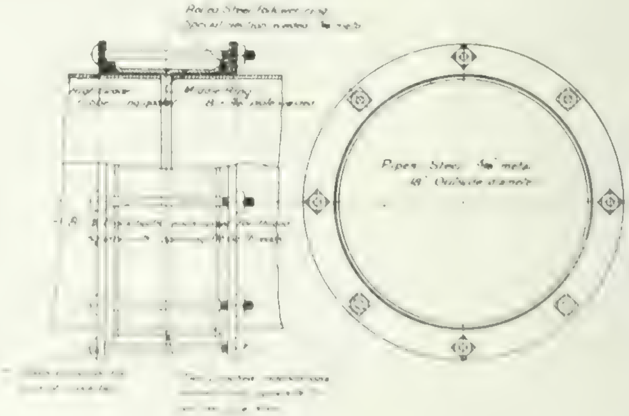
Canada having generally a very dry climate, the quantity of mechanically (not chemically) included water or moisture in Canadian coal as bought or sold averages only about 3 per cent. Of course, during prolonged or excessive wet weather this amount of contained or free water would be augmented, especially where coal is stacked in uncovered yards, or where purposely adulterated or diluted with water from a hose. Evidently small soft coal and coal dust absorb far more moisture than larger harder coals. Damp or damped coal is additionally friable or liable to waste by crumbling. In other words, where coal contains, say, 5 per cent. of free moisture—as it usually does in the United Kingdom—then in every ton there is 1 cwt. of useless water, so that the consumer on every pound's worth of coal purchased gets only 19s. worth of coal and loses a shilling for the coal's contained free water or moisture, which must not be confused with the water chemically combined as a constituent of the native coal.

Good coals as sold in London seldom contain more than 8 per cent. of free water or moisture, with an average probably approximating 7½ per cent.

AN EFFICIENT PIPE JOINT.

A very efficient pipe joint has been used recently on the new pipe line being installed for the Moose Jaw water supply. The water is being brought to Moose Jaw through nineteen miles of eighteen-inch plain end steel pipe.

There are two joints of this kind which are very similar; one is made by the Custer Coupling Company, of Bradford, Pa., and the other by C. J. Dresser Company, of the same place. The Dresser Company prefer a gland detail similar to that used on an ordinary piston rod. The Custer joint, which was adopted on the Moose Jaw water supply, compresses the rubber gasket in a different way, and gives some latitude for variations in the size of pipe and couplings. It is stated that hundreds of these joints were made on the Moose Jaw work in a foot or more of water. The accompanying sketch gives a clear idea of the joint.



The above information, together with the sketch, has been very kindly furnished us by Walter J. Francis & Co., of Montreal, who are the consulting engineers on the Moose Jaw water supply.

THE VENTILATION OF SEWERS.*

By T. De Courcy Meade.†
